(*labour*). These are deeply degraded below not only the Brahmins, but the other two castes; and even the reading of the Vedas or sacred books is forbidden to them. Besides these four grand divisions, the Hindoos have many subdivisions of caste, and no fewer than thirty-six are reckoned which are all inferior to the Sudra. These descend, according to the mythological history of the Hindoos, from the "Burren Sunker" or mixed class, proceeding from the confusion of castes which took place under the reign of a wicked and irreligious monarch. Finally, the Pariahs and some other races are considered as having no caste at all, and mere outcasts from humanity. Traces of the system of caste, which confines employments to hereditary classes, are to be found in the institutions of many countries, and in the history of many more. That the Egyptian nation was thus divided, is well known; and it is supposed that similar institutions prevailed in the ancient Assyrian empires. If Plato can be relied on as an authority, the Athenians in the first ages of their commonwealth were divided into five classes of the same description — priests, handicraftsmen, shepherds and hunters, ploughmen, soldiers. And it is said that the Cretans were divided, according to the laws of Minos, in the same manner as the Egyptians.

CA'STELLATED. (Lat. castellum, *a castle.*) In Architecture, a building in the style of a castle.

CA'STING. (Dan. kaster, *to throw.*) In Architecture, a term used to denote the bending of the surfaces of a piece of wood from their original state, caused either by the gravity of the material, or by its being subject to unequal temperature, moisture, or the uuuniform texture of the material. Called also Warping.

CASTING. In Foundery, the running of liquid metal into a mould prepared for that purpose. *See* FOUNDERY.

CA'STING OF DRAPERIES. In Painting, the disposition of the folds of the garments wherewith the figures in a picture are clothed. Carlo Maratti thought that the disposition of drapery was a more difficult art than even that of drawing the human figure, and that a student might be more easily taught the latter than the former. Inferior painters enter into the minute discriminations of quality in drapery; but, as Sir Joshua Reynolds has well observed in his Fourth Discourse, with the historical painter "the clothing is neither woollen nor linen, nor silk, satin, nor velvet: it is drapery; it is nothing more."

CA'STING OFF COPY. In Printing, is to ascertain accurately how many pages in print a given quantity of manuscript copy will make; or how many pages a given quantity of printed copy will make when the size of the book and the type are changed; also when a given quantity of manuscript copy is delivered, with directions that it is to make a certain number of pages in print, to determine the size of the page and the size of the type. This is usually done by composing a line or two of the copy, when, supposing a line and a half of it makes a line of print, it becomes a mere arithmetical question. Supposing there are 12,000 lines of copy, it will make 8,000 lines in print, which, at 24 lines to a page, will be 333 pages, and with the title, short pages, &c. equal 14 sheets in 12mo.; about the general quantity in a volume of modern novels.

CA'STLE. (Lat. castellum; or Sax. caꞅtel.) In Architecture, a building fortified for military defence; also a house with towers, usually encompassed with walls and moats, and having a donjon or keep in the centre. The principal castles of England at present are, the Tower of London, Dover, Windsor, Norwich, &c.; but at one time those of Harwood, Spofford, Kenilworth, Warwick, Arundel, and others might have vied with them in importance. The characteristics of a castle are its valla (embankments) and fossæ (ditches); from the former of which the walls rise, usually crowned by battlements, and flanked by circular or polygonal bastions at the angles formed by the walls; these latter were pierced for gates with fixed or draw bridges and towers on each side; the gates, which were of considerable strength, were further guarded by descending gratings, called portcullises; all the apertures were as small as they could be made, consistently with internal lighting. The component parts of a castle were, the foss or mote, with its bridge; the barbican, which was in advance of the castle, being a raised mound or tower, the outer walls having terraces towards the castle, with their bastions, as above mentioned; the gate-house, flanked by towers, and crowned with projections, called machicolations, through which heavy materials or molten lead were dropt on the assailants entering the gateway; the outer ballium, or area within the castle, which was separated from the inner ballium by an embattled wall with a gate-house, and in which the stables and other offices usually stood; and the inner ballium, for the residence of the owner or governor and his retinue; this, at one corner, or in the centre, had a donjon or keep tower, which was the strong hold of the place, wherein was a state apartment; a well and a chapel; the former usually, and the latter frequently, are found in ancient castles.

For further information on the subject the reader is referred to *King's Mun. Antiq.* fol. 4 vols; the *Archæologia* in several places; *Leland's Collect.* vol. ii.; *Woolnoth's Ancient Castles of England and Wales*, &c. &c.

CA'STOR. The generic name of the beaver. (*Castor fiber*, Linn.)

CA'STOR. A peculiar concrete substance, contained in oval pouches situated near the anus of the *Castor fiber* or *beaver*. There are four of these pouches; two contain a species of fat; while the two larger ones include in their membranous cells a viscid fetid substance, which is the *castor* of the Materia Medica. It is imported from Russia, Prussia, and Poland, and from Canada: the latter, known in trade under the name of *New England castor*, is very inferior. It is said to be an antispasmodic.

CA'STOR AND PO'LLUX. The name given to a meteor which sometimes appears at sea, attached to the extremities of the masts of ships under the form of balls of fire. When one ball only is seen, it is called Helena. The meteor is generally supposed to indicate the cessation of a storm, or a future calm; but Helena, or one ball only, to portend bad weather.

CA'SUA'RINA'CEÆ. (Casuarina, one of the genera.) A curious natural order of plants, inhabiting New Holland, some parts of India, and the South Sea Islands, with long slender creeping branches, resembling those of *Equisetum*, and bearing scales only in the place of leaves. The order is nearly allied to *Myricanceæ*, and belongs to the most imperfect forms of Exogenous vegetation.

CA'SUIST, CA'SUISTRY. In Theology, a casuist is a doctor charged with the decision of cases of conscience. The Jesuits were distinguished for the cultivation of this mixed subject of theology and ethics; which was admirably calculated to promote the crafty policy of that order. The science of casuistry, however, has been cultivated in the Protestant as well as the Papal church; and until very recently there was a professor of casuistry at Cambridge. (See *Mayer's Bibliotheca of Casuists.*)

CAT. *See* FELIS, or FELINÆ.

CAT. A ship employed in the coal trade.

CAT. Tackle by which the anchor is raised to the cathead. See *Falconer's Dict.*

CA'TABA'PTISTS. (Gr. κατα, *against*, and βαπτιζω, *I baptize.*) In Ecclesiastical History, a general term to designate all the sects which have denied the necessity of baptism generally, or have opposed infant baptism. *See* BAPTISTS, QUAKERS, SOCINIANS, &c.

CA'TACA'USTICS. (Gr. κατακαιω, *I burn.*) In Optics or Geometry, are the *caustic* curves formed by the reflection of the rays of light, and so called to distinguish them from the *diacaustic*, which are formed by refracted rays. *See* CAUSTIC.

CA'TACHRE'SIS. (Gr. κατα, in the sense of *beside*, and χρησις, *use.*) In Rhetoric, a figure by which a word is used in a sense analogous to its own. *See* METAPHOR.

CA'TACLE'SIUM. (Gr. κατα, *against*, and κλειω, *I enclose.*) A name applied sometimes to such fruit as that of *Mirabilis*, which consists of a membranous indehiscent pericarp enclosed within a hard pericarp-like tube of the calyx.

CA'TACLY'SM. (Gr. κατακλυσμος, *an inundation, a deluge.*) Geologists apply the word to signify the various great inundations which they conceive to have occurred at different periods in the history of the globe.

CA'TACOMBS. (Gr. κατα, *against*, and κυμβος, *a hollow place.*) In Architecture, subterraneous places used for burying the dead. The hypogæa, crypta, and cimeteria of the ancients were used for the same purpose. In some cities those vast excavations were made use of for other purposes than those of sepulture; at Syracuse, for instance, the same cavern served for a prison as well as a public cemetery. It has been said that in the early ages of Christianity they also served as places of devotion. The most celebrated for their extent are those of Rome, Naples, Syracuse, &c.; and the more modern ones of Paris, which have been formed by quarrying for the stone with which the city is built.

CA'TACOU'STICS, or CATAPHO'NICS. (Gr. κατα, *about*; ακουω, *I hear*; φωνεω, *I speak.*) The science of reflected sounds; or that part of acoustics which treats of the properties of echoes, or in general of sounds which do not come to the ear directly but after having been reflected by some substance. *See* ECHO and SOUND.

CA'TAFA'LCO. (Ital. *a scaffold.*) In Architecture, a temporary structure of carpentry, decorated with painting and sculpture, representing a tomb or cenotaph, and used in funeral ceremonies. That used at the final interment of Michael Angelo at Florence was of the most magnificent description, and perhaps unequalled as to the art employed on it by any used before or since.

CA'TALE'CTIC. (Gr. καταληκτικος, *deficient.*) In Greek and Latin poetry, a verse wanting one syllable of its proper length: *acatalectic*, a verse complete in length; *hypercatalectic*, having one syllable too many; *brachycatalectic*, wanting two syllables.

CA'TALEPSY. (Gr. καταλαμβανω, *I seize.*) A disease in which the functions of the organs of sense and

motion are suspended, whilst the heart continues to pulsate. The patients are said to be in a *trance;* and in this state they remain for some hours, or even days. Ammoniacal and etherial stimulants are the most effectual restoratives.

CA'TALOGUE RAISONNE'. In Bibliography, a catalogue of books, classed under the heads of their several subjects, and with a general abstract of the contents of works where the title does not sufficiently indicate it; thus serving as a manual, to direct the reader to the sources of information on any particular topic. The want of alphabetical arrangement is supplied by an index at the end. The catalogue of the French *Bibliotheque Royale* (10 vols. fol. 1739—53) is said to be the best work of this description, as far as it extends.

CA'TAMARA'N. A sort of raft used chiefly by the Indians on the Coromandel coast for the purposes of fishing. It is composed of three pieces of wood lashed together, the middle piece being longer and broader than the others; and it is almost the only kind of boat that can live in the surf that prevails on that coast. Catamaran was also the name given to the floating batteries with which the French at the commencement of the present century meditated the invasion of England.

CATAME'NIA. (Gr. κατα, *according to*, and μην, *a month.*) The monthly uterine evacuation.

CA'TAPE'TALOUS. (Gr. κατα, *against;* πεταλον, *a petal.*) When the petals of a flower are held together by stamens which grow to their bases, as in the mallow.

CA'TAPHRA'CTED. (Gr. καταφρακτος.) Covered with a hard callous skin, or with horny or bony plates or scales closely joined together. Among the ancients, cavalry equipped with complete defensive armour were termed *equites cataphracti.*

CA'TAPLASM. (Gr. καταπλασσω.) A poultice.

CA'TAPULT. (Gr. κατα, *against*, and πελτη, *a shield.*) A military engine used by the ancients for throwing stones, long darts, or javelins. The catapult is often confounded with the balista; but the latter engine seems to have been chiefly used for the purpose of propelling stones, while the former more frequently was employed with other missiles. Their size and construction were various, but the principle of action was the same in all; namely, the elastic force with which twisted rope uncoils itself.

CA'TARACT. (Gr. καταρρασσω, *I confound.*) An opacity of the crystalline lens of the eye, producing confused or indistinct vision, or total blindness, according to the less or greater extent of the thickening: it is sometimes rapid, and often very slow in its progress. It is distinguished from *gutta serena* by the visible opacity of the lens, and by the iris contracting upon exposure of the eye to light. This disease is curable either by depressing or extracting the lens, operations which are performed with wonderful dexterity by some of our oculists.

CATA'RRH. (Gr. καταρρεω, *I flow down.*) The complaint commonly called a *cold in the head*, generally attended by running from the eyes and nose, sneezing, hoarseness, and commonly ending in cough. It is produced by sudden changes of air or temperature, and by exposure to draughts of air. In its usual form domestic remedies relieve it,—diluents, mild aperients, and abstinence from wine and animal food; but when attended by fever, headache, tightness about the forehead, and difficult breathing, it often requires more serious attention, for, if neglected, it may lead to much mischief.

CA'TARRHINES, *Catarrhina.* (Gr. κατα, *at*, and ῥιν, *nose.*) A tribe of Quadrumanes, including those which have the nostrils approximated, and the intervening septum narrow; as in the apes of the old world.

CATA'STROPHE. (Gr. καταστρεφω, *I overturn.*) In modern literary language, the final event of a drama or romance, to which the other events are subsidiary. The περιπετεια, or revolution, indicated by Aristotle as one of the parts of the drama, was a change in the fortunes of the principal personages of the play; as, the fall of Œdipus from sovereignty into extreme misery and banishment, in the *Œdipus Tyrannus.* Some such change is generally involved in the idea of a catastrophe: thus, marriage is the ordinary catastrophe of a comedy or a novel, as some disastrous change is that of a tragedy.

CA'TCH-DRAINS. Open drains across a declivity to intercept surface water. The term is sometimes also applied to under drains across a declivity.

CA'TCHWORK-MEADOWS. Grass lands with very regular surfaces, subjected to irrigation, the water as it descends the declivities being intercepted by catchdrains.

CA'TECHISM. (Gr. κατηχεω, *I instruct.*) A form of instruction by question and answer, appropriated by general usage to instruction in religious subjects, and more especially to the set forms which most churches have authorised for the instruction of children in the elements of religion. The English church catechism is intended to be an exposition of the vow made at baptism, and till the time of James I. consisted only of the *renunciation* or repetition of the baptismal vow, the creed, and the Lord's Prayer. The latter portion, explaining the nature of the sacraments, was added after the conference at Hampton Court. The catechism of the Council of Trent, or *Catechismus ad Parochos*, was set forth by the Roman Catholic divines for the use and direction of the clergy, and contains an ample account of the whole sum of the Romish doctrines. It was approved by Pius V., and published in 1566. (See *Bingham's Antiq.* b. x. ch. 1, 2.)

CA'TECHU. A Japanese word, signifying the juice of a tree. The extract of the *Acacia catechu*, an astringent substance, consisting of tan and extractive matter, imported chiefly from Bengal and Bombay. Its principal use is in medicine.

CATECHU'MEN. (Gr. κατηχουμενος.) He who learns the elements of any science: one who is undergoing a course of religious instruction with a view to his admission into the church. The Christian society in the early ages was divided into two classes, Fideles and Catechumeni; the former being those who had been admitted by baptism into the entire privileges of the church, the latter such as were preparing for that admission.

CA'TEGOREMA'TIC. (Gr. κατηγορεω, *I predicate.*) In Logic, when a word is capable of being employed by itself as a *term*, or predicate of a proposition.

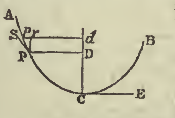
CATEGO'RICAL PROPOSITION. (Gr. κατηγορεω, *I declare something of another.*) In Logic, a proposition which affirms or denies, absolutely and without any condition, that the subject does or does not agree with the predicate. (*See* PROPOSITION.) Categorical propositions are said to be pure (those which simply assert one thing of another), and modal (those which assert one thing of another under a certain mode or form). But this is a distinction arising out of the poverty of language only, and no essential difference between the two classes; *e. g.* "the king reigns" is a pure categorical proposition; "the king reigns justly" is said to be modal. But it is evident that if our language had a single word to express the whole idea (to reign justly), the latter would be called pure likewise. All cases of modal categoricals may probably be resolved into similar instances of the deficiency of words to express complicated notions.

CA'TEGORY. (Gr. κατηγορια.) In Logic and Metaphysics, a Greek word, signifying originally that which may be said or predicated of a thing; a general term in reference to a less general one which is included under it. By Aristotle, from whom the word, and its corresponding Latin term *predicate*, was borrowed by the schoolmen, it was applied to denote the *most general* of the attributes that may be assigned to a subject. Of these he attempted an enumeration, under the names of substance, quantity, quality, relation, place, time, condition, state or habitude, action, and passion. The word has been revived in modern times by Kant, to express the most general of the modes in which a thing can be raised from an object of sense to an object of intellect; or, in other words, the forms or conditions which must pre-exist in the understanding, in order that an act of intelligence may take place. For an account of these see art. KANTIAN PHILOSOPHY. The difference between the categories of Kant and those of Aristotle is this, that the latter are mere generalizations from experience, which may consequently be multiplied indefinitely; whereas the former result from a professedly exhaustive analysis of the human understanding as it is in itself, or formally, that is, apart from all consideration of its object-matter.

CATENA'RIAN ARCH. (Lat. catena, *a chain.*) In Architecture, an arch whose form is that of a chord or chain suspended from two fixed points at its extremities.

CATE'NARY. (Lat. catena, *a chain.*) The curve into which a chord or flexible chain of uniform density and thickness forms itself when suspended or allowed to hang freely from two points. This curve was first noticed by Galileo, who proposed it as the proper figure for an arch of equilibrium; but he imagined it to be the same as the parabola. Its true nature was first demonstrated by James Bernoulli, and its various properties soon after pointed out by John Bernoulli, Huygens, and Leibnitz. It is interesting on account of the light it throws on the theory of arches, and also by reason of its application to the construction of suspension bridges.

The equation of the catenary may be found as follows: let A and B be the points of suspension, and C the lowest point in the curve. Draw C D perpendicular to the horizon, and through any two points P and p very near each other, draw P D and $p\,d$ perpendicular to C D; draw also P r parallel to C D, and let P S be the tangent at P. Now, the chain having assumed this form, the equilibrium would not be disturbed by supposing the part C P to become rigid. In this case it would be kept at rest by three forces; namely, the tension at its two extremities, and its own weight. The tension at C is exerted in the direction C E or $p\,r$, that at P in the direction P S or Pp, and the weight in the vertical Pr. These three forces are therefore, by the principles of mechanics, proportional to $p\,r$, p P, and P r; that



is, making $CD = x$, $DP = y$, and $CP = z$, proportional to the differentials of these quantities, or to dx, dy, dz. But the tension CE (arising from the part of the chain CB) is constant; suppose it therefore equal to a, and the chain being uniform, the weight of CP is proportional to its length, or to z; therefore we have $a : z = dy : dx$, or $a\,dx = z\,dy$, which is the differential equation of the curve. On substituting $\sqrt{dz^2 - dx^2}$ for dy, and integrating, there results $x^2 + 2\,ax = z^2$, which is an equation between the arc and the absciss. The curve cannot be expressed by a simple algebraic equation between the absciss and ordinate, and is consequently of the mechanical kind. The constant quantity a is called the parameter; and one of the most remarkable properties of the curve is, that the rectangle contained by the parameter and an ordinate is equal to the natural logarithm of the ratio of the parameter to the sum of the parameter, the absciss, and the arc.

CATE'NULATE. (Lat. catena, *a chain.*) When a surface presents a series of elevated ridges or oblong tubercles resembling a chain.

CA'TERPILLAR. The name of the larvæ of Lepidopterous insects.

CA'THARI. (Gr. καθαρος, *pure.*) An oriental sect of Christians. *See* PAULICIANS.

CATHAR'TIC. (Gr. καθαιρω, *I purge.*) That which increases the action of the bowels. The term is commonly applied to medicines which do this with some degree of violence: among the milder cathartics, jalap, senna, calomel, and saline purges are the most used; those which are *drastic* are croton oil and elaterium.

CATHA'RTIN. The active or purgative principle of senna.

CAT-HEAD. A Nautical term, signifying a strong inclined piece of timber projecting from either bow of a ship, to which the ring of the bower anchor is secured. The block or pulley hooked to the ring is called the *cat-block*, the rope the *cat-fall.*

CATHE'DRAL. (Gr. καθεδρα, *a seat or throne.*) The principal church of a diocese, in which is the throne of the bishop. The term cathedra was originally applied to the seats in which the bishop and presbyters sate in their assemblies, which were held in the rooms in which the worship of the first Christians was also performed before they had liberty to erect temples for that purpose. In after times the choir of the cathedral church was made to terminate in a semicircular or polygonal apsis; and in the recess thus formed were placed the throne of the bishop in the centre, and seats of an inferior class for presbyters. In modern cathedrals the bishop's throne is in the choir, and generally on the south side. (*Bingham*, viii. 6. 10.)

CA'THETA and CATHETUS. (Gr. καθετος, *let down.*) In Architecture, a vertical line falling from the extremity of the underside of the cymatium of the Ionic capital through the centre of the volute.

CA'THETER. (Gr. καθιημι, *I thrust into.*) A tube which may be introduced by the urethra into the bladder for the purpose of drawing off the urine.

CA'THOLIC. (Gr. καθολικος, *universal.*) A word which occurs in the New Test. in the titles of certain of the Epistles,—those of James, Peter, and John,—signifying that they are addressed to the whole or universal body of Christians, and not to a particular section of them. Hence the term has been used in later times to distinguish the church of Christ from all heretics and schismatics, and has been assumed by particular churches either to separate themselves from all others, as the Romish; or to include themselves as individual members of the universal body, represented under different and subordinate local names, as the English episcopal church. The Romish church appeals to the decisions of the Council of Trent for its most complete and definite rule of faith, and allows no one to be a member of the Catholic church who rejects any of the tenets therein enforced. (*See* art. ROMAN CATHOLIC.) The English church considers itself a member of the Catholic, but passes no judgment as to what variations from its own formularies incur the guilt of heresy and incapacitate from such incorporation. *See* art. CHURCH.

CATHO'LICON. (In old Pharmacy.) An universal medicine.

CA'TKIN. The English name of the inflorescence of the poplar, willow, and similar trees. A catkin is a close spike, composed of scales overlapping each other, and falls off the parent plant as soon as its office of flowering or fruiting is accomplished.

CATO'PTRICS. (Gr. κατοπτρον, *a mirror;* compounded of κατα and οπτομαι, *I see.*) Is that part of the science of optics which treats of the laws of reflected light, and the phenomena of vision produced by reflection. For details connected with this interesting branch of natural philosophy, see the terms MIRROR, OPTICS, REFLECTION.

The principal authors who have treated of Catoptrics are, Euclid; Alhazen and Vitellion, in the 11th and 12th centuries; James Gregory in his *Optica Promota;* Barrow, Smith, Tacquet, and all modern writers on the subject of Light or Optics.

CAT'S-EYE. A beautiful siliceous mineral (probably quartz), penetrated by fibres of asbestos, which, when polished, reflects an effulgent pearly light, much resembling the mutable reflections from the eye of a cat. Hence the Anglicised French term *chatoyánt.*

CAT'S-TAIL GRASS. In Botany, a valuable meadow grass, usually forming part of all good lowland pastures. It is the *Phleum pratense*, a plant with a soft narrow cylindrical head, resembling that of the meadow foxtail.

CA'TTLE. Domesticated animals of the cow kind, which are found accompanying man in every civilized country, and in every climate. The native country of the type of British cattle is supposed by some to be Asia, and by others to be Africa; but in this case, as in all others where an animal or a plant has been long in a state of domestication, the origin of the species is involved in obscurity. When the tame cattle of any country are allowed to run wild and breed in that country, uncontrolled by man, the habits which belong to the animal in its savage state become, in the course of three or four generations, modified according to the natural supplies of food and the character of the climate. Hence, though cattle are not indigenous to Britain, South America, or the Sandwich Islands, we have in the former country a breed of wild cattle in one or two gentlemen's parks, as at Chillingham in Northumberland, which are quite different from the wild cattle of the fertile soils of South America, as these again are different from the wild cattle of the Sandwich Islands, though all undoubtedly the descendants of tame animals. Those in the Sandwich Islands, in particular, are known to be the offspring of the tame cattle that were left there by Vancouver, and which can now be only caught alive by entrapping them in disguised pits; into one of which the unfortunate botanist Douglas fell, and was gored to death by a bull who happened to be in it at the time. The domestic cattle of Britain may be divided into two races: those of large size adapted for the plains, and those of smaller size adapted for the mountains. Of each of these classes there are several breeds; such as the Highland and the Welch cattle, among the latter; and the Lancashire, the Yorkshire, and the Herefordshire cattle, among the former. There is also an intermediate breed, adapted for moderately hilly countries; such as the Galloway and Fife breeds in Scotland, and the Alderney and Guernsey cattle in England. The best beef brought to the London market is that of cattle of the Highland breed fed in English pastures, or on turnips. The best milk cow for general purposes is the Ayrshire; the best for cream and butter, the Alderney; and the best for immense quantities of milk, the Lancashire. Hence the latter are generally employed in public dairies, the Ayrshire by farmers and cottagers, and the Alderney by the higher classes.

CA'TULUS. (Lat. catulus, *the young of any thing.*) The old botanical name of the catkin of a plant, which see.

CAU'DA. (Lat.) That portion of an animal which is supported by vertebræ behind the sacrum; or which, as in fishes, have inferior spinous processes. In Entomology it signifies that part of the abdomen which becomes suddenly slender, and terminates in a long jointed tail, as in the scorpion.

CAU'DAT. (Lat. cauda, *a tail.*) When the apex of any organ in a plant is prolonged into a long slender point; this is not of rare occurrence, and is more especially common in Araceous and Aristolochiaceous plants.

CAU'DEX. (Lat. caudex, *a trunk.*) The Linnæan name of what is now more generally called the axis of vegetation; the woody centre round which the leafy and leaf-like organs are arranged. The *caudex ascendens* was the stem, the *c. descendens* the root of a plant.

CAUDI'CULA. (Lat. dim. of caudex.) A thin, elastic, semitransparent process of the pollen masses of Orchidaceous plants, by means of which the pollen is brought in contact with the stigma or stigmatic gland. Its exact nature, use, and origin are unknown.

CAUL. The trivial appellation of the *amnion* when it comes away in child-birth. It is regarded by the superstitious as a charm against shipwreck.

CAULI'COLUS. (Lat. caulis, *a stalk.*) In Architecture, the small stalk under the volutes of the Corinthian capital, which it seems to support.

CAULI'CULUS. (Dim. of caulis, *a stem.*) In Botany, the slender part which connects the cotyledon of a seed with the radicle. It is usually considered a part of the radicle, but recent observations seem to show that it is rather an extension of the stem. Its office is to lengthen rapidly when germination takes place, and thus to bring the true radicle into contact with the earth upon which it has to feed.

CAU'LINE. (Lat. caulis, *a stem.*) Any thing that grows to, or springs from, the stem of a plant. Cauline

leaves are those which grow upon the stem, prickles such as are borne by the same part, and so on.

CAULK, or CALK, to stuff the seams or openings between the planks of a ship with oakum, which is rope untwisted into its original state of fibre. The oakum is forced in by a caulking chisel and mallet. It has been found necessary, when a ship has worked the oakum out of the seams, to fill them with rope. Caulking affords fixedness to the whole frame, and is therefore a great support. The quantity of oakum used in a large ship is very great; in a large three-decker it is near 30 tons, or upwards of four cables.

When the seams are caulked, melted pitch is poured on the seams of the decks out of a pitch ladle; in other places it is laid on with a pitch mop: this is called *paying* the seams.

CAULOCA'RPOUS. (Gr. *καυλος, the stem of a plant*, and *καρπος, fruit.*) A name applied by De Candolle to such plants as, like trees and shrubs, annually produce flowers and fruit on their branches without perishing.

CAUSE. Four kinds of causes have been distinguished by logicians: — *the material, the efficient, the formal*, and *the final*. The *material* cause of a thing is that out of which that thing is made; in other words, that which is the ground of the possibility of a thing's coming into existence: *e. g.* the marble out of which a statue is made. The *efficient* cause is that in which resides the moving power requisite in order to render the possible existence actual; as the sculptor. The *final* cause of the thing is that very thing in its completeness; as the statue when made. The *formal* cause is that which must supervene to the matter, in order to give the thing its precise individual existence as that thing and no other; as the shape which the sculptor communicates to the marble. This distinction is derived originally from Aristotle, with whom, however, it is rather a metaphysical than a logical determination. *See* ARISTOTELIAN PHILOSOPHY.

In popular language, the *final* cause is synonymous with the purpose to which any object is supposed to contribute, though that purpose be wholly external to the thing caused.

CAU'STIC CURVE. (Gr. *καιω, I burn.*) In the Transcendental Geometry, is the name given to the curve to which the rays of light, reflected or refracted by another curve, are tangents. Caustics are consequently of two kinds, *catacaustics* and *diacaustics;* the former being caustics by reflection, and the latter caustics by refraction. Catacaustics are generated thus: Suppose rays, as B M, B M′, &c. (*fig.* 1.) to issue from a luminous point B, and to be reflected by the curve A M D, so that the angle of incidence equals the angle of reflection; the curve line H F F′, which touches all the reflected rays (produced, if necessary), is called the *catacaustic*, or caustic by reflection. *Diacaustics* are produced in a way entirely similar. Thus: Suppose rays, B M, B M′, &c. (*fig.* 2.), issuing from a luminous point B, to be refracted by the curve A M M′, so that the sines of incidence are to the sines of refraction in a constant given ratio; then the curve H F F′, which touches all the refracted rays, is called the *diacaustic*, or caustic by refraction.

fig. 1.

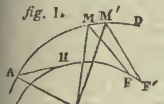


fig. 2.

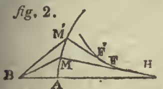


The term *caustic* has been applied to these curves because the rays of light being collected along the curve in a greater quantity than elsewhere, heat is produced, particularly if the collection of rays is considerable. In parabolic mirrors, when the luminous rays strike the mirrors in a direction parallel to the axis, the caustic merges in a single point, which is the focus of the mirror. All the conic sections have this property, that luminous rays issuing from one focus are reflected by the curve into the other focus; but in respect of all other curves, the several reflected pencils are collected, not into a single point, but into a series of brilliant points or foci, the assemblage of which forms a bright curved track, or caustic, which is mathematically defined as above.

The attention of geometers was first called to this species of curve lines by Tchirnhausen, who demonstrated some of their properties to the Academy of Sciences of Paris in 1682. One property, common to all of them, is remarkable; namely, that when the curves by which they are produced are algebraic, the caustics are rectifiable; in other words, straight lines can be found to which they are equal. In fact, any portion H F of the catacaustic (*fig.* 1.) is equal to the difference between the sums of B M and M F, and B A and A H; or $HF = BM + MF - (BA + AH)$. In the diacaustic (*fig.* 2.) we have for the length of the curve $HF = AH - MF - n\,(BM - BA)$, where n is the constant ratio of the sine of incidence to refraction. If, therefore, the lengths of the radii and tangents can be expressed algebraically, the length of the caustic can also be exhibited by an algebraic expression. This circumstance having been noticed before the invention of the infinitesimal calculus, excited much interest among mathematicians, because it was then generally imagined that no curve line could be rectified.

The catacaustic may be experimentally exhibited by exposing the inside of a smooth bowl, containing any liquid not diaphanous (milk, for example, or still better, ink) to the sunbeams, or any strong light. The caustic, which in this case is an epicycloid, will appear beautifully delineated on the surface of the fluid. Another experiment, proposed by Sir David Brewster, exhibits the curves still more strikingly. Take a plate of polished metal, thin enough to be bent easily into a concave form, and place it perpendicularly on a sheet of white paper. If we expose this apparatus to the sun, holding the plane of the paper in such a manner that it may pass near the sun, without, however, intersecting it, the caustic will be exhibited on the paper as a well-defined curve of light. The interior part will be more brilliant than the exterior, and the light will diminish gradually and very rapidly at a little distance from the caustic. By varying the size of the plate, and bending it into curves of different shapes, all the different kinds of catacaustics, with their points of inflexion, &c., will be beautifully developed. (*Brewster's Optics, Cabinet Cyclopedia.*)

This subject being intimately connected with the concentration and dispersion of the rays of light by reflecting and refracting surfaces, is of great importance in practical optics. (De la Hire, *Traité des Epicycloides; Smith's Optics;* J. Bernoulli, *Opera Omnia*, vol. iii.; L'Hopital, *Analyse des Infiniments Petits;* Gergonne, *Annales des Mathematiques;* De la Rive, *Dissertation sur les Caustiques; Ency. Met.* art. "Light.")

CAU'STIC LUNAR. Fused nitrate of silver.

CAU'STICS. Substances which corrode and destroy the texture of the skin and of organized bodies.

CAU'TERY. The ancients divided cauteries into *actual* and *potential*. The former term is applied to red-hot iron; the latter to pure potash.

CAU'TIONARY. In Scottish Law, is the obligation by which a party becomes surety for another; answering to the English term guarantee. It is defined by Stair, "the promise or contract of a man not for himself but another." The guarantor is termed "cautioner."

CAVÆ'DIUM. (Lat.) In Ancient Architecture, an open quadrangle or court within a house. The cavædia described by Vitruvius are of five species; Tuscanicum, Corinthium, Tetrastylon (with four columns), Displuviatum (uncovered), and Testudinatum (vaulted). Though some authors make the cavædium the same as atrium and vestibulum, it was essentially different.

CA'VALIER. In Fortification, a sort of interior bastion, several feet more elevated than the principal bastion of the fortress in which it is formed. The use of the cavalier is twofold: it serves either to defilade the works from the fire of an enemy on an adjacent height, or to command the trenches of the besiegers. Cavaliers are sometimes constructed in the gorges, or on the middle of the curtain, and their form is the semicircular; but when they are within the bastion they are now built with straight faces and flanks parallel to those of the work in which they are placed. French cavaliers are works raised by the besiegers on the glacis of a fortress, for the purpose of enabling them to direct a fire of musketry into the covered way.

CA'VALIER (derived probably from the Latin word caballus, *a pack-horse*), was used originally in a general sense for a horse soldier; but the term has acquired historical importance from its having been applied to the adherents of Charles I. in contradistinction to the *Roundheads* (quod vide), the supporters of the parliament.

CA'VALRY. (Fr.) A body of soldiers furnished with horses for war. This arm can boast of high antiquity, and is so peculiarly useful and necessary for a great variety of operations, that it has in all ages been held by the greatest generals in high estimation. The efficacy of cavalry arises principally from its adaptation to speedy movements, which enables a commander to avail himself immediately of a decisive moment when the enemy exposes a weak point, or when disorder appears in his ranks, for completing his defeat by disconcerting him by a sudden attack. It is singularly useful in protecting the wings and centre of an army, for furnishing detachments, for escorts, for forming blockades, for intercepting the supplies of the enemy, for foraging, for procuring intelligence, for covering a retreat, &c. The successful services which troops of this description have performed, and the number of decisive advantages which have been obtained by means of them in the most important battles of which history ancient and modern furnishes the details, prove incontestably the utility of this arm. The use of cavalry, however, is necessarily limited by the nature of the ground. Open and level countries are favourable to its operations; in forests, in

mountainous districts, on a marshy soil, &c. It is but of little avail. Among the Greeks and Romans, the cavalry was regarded as the most respectable class of troops, and its ranks were supplied especially from the *elite* of the nobility. In the middle ages a similar feeling seems to have prevailed; for, in the early French monarchy, and in the Anglo-Saxon kingdoms of Britain, the men of wealth and noble birth distinguished themselves in the field from those of inferior rank by being well armed and mounted on horses; and from the mode of warfare then practised, as well as from the peculiarities adopted in the organization of troops, cavalry constituted almost the only efficient arm of battle down to the introduction of standing armies.

The invention of gunpowder, and the subsequent employment of artillery in the field, deprived the heavy-armed cavalry of those times of all the advantages it possessed over the infantry, and rendered its movements awkward and inefficient. It was reserved, however, for Gustavus Adolphus to show the real utility of this arm by discovering the services on which it should properly be employed, and by stripping it of all unnecessary encumbrances to supersede by *rapidity of motion* the value it formerly possessed in *weight*. Since that time cavalry has often turned the scale of fortune in war: the battle of Rossbach, for instance, in 1757, one of the most brilliant victories either of ancient or modern times, was entirely decided by this arm.

Modern cavalry consists of two grand classes—*heavy* and *light* horse; which are again susceptible of further subdivisions, according to the purposes to which they are subservient. The British cavalry consists of two regiments of life guards, the royal regiment of horse guards, seven regiments of dragoon guards, and seventeen regiments of light dragoons, of which four are called hussars and four lancers. (For the history, use, accoutrements, and arms of these different branches, see the separate articles.) A regiment of cavalry is divided into four squadrons, and each of these into two troops. A troop consists of 80 men; and to each troop there is attached a captain, a lieutenant, and a cornet.

CAVATI'NA. (It. dimin. of cavata, *cut off.*) In Music, a species of air, generally short, and having neither a repeat nor second strain, often inserted in obligato recitatives. The sudden changes from recitative to a measured movement and the reverse are useful in producing expression.

CA'VEA. (Lat.) In Ancient Architecture, the subterranean cells in an amphitheatre wherein the wild beasts were confined in readiness for the fights of the arena. In the end, the amphitheatre itself, by synechdoche, was called cavea; in which sense it is employed by Ammianus Marcellinus: "Alter in amphitheatrali caveâ cum adfuturus spectaculis introiret." Lib. xxix. cap. I.

CA'VEAT. In Law, a notice or caution given by a party interested to a judge or other officer, in order to stay proceedings by him; as, in the spiritual courts, a caveat is put in to stop the granting of probate or administration.

CAVE'TTO. (Lat. cavus, *hollow.*) In Architecture, a hollowed moulding, whose profile is a quadrant of a circle: it is principally used in cornices.

CA'VIA. The Linnæan generic name of a Cuvierian family of Rodents, including the guinea-pig,—*Agouti*, *Paca*, and *Capibara*.

CAVIA'RE. The salted roe of the sturgeon, much esteemed by the Russians as an article of food, and frequently brought as a delicacy to this country; it is an oily unwholesome article.

CA'VICORNS, *Cavicornia*. (Lat. cavus, *hollow*, and cornu, *horn.*) The name of the tribe of Ruminants comprehending those which have the horns hollowed out like a sheath and implanted on bony processes of the os frontis, as in the antelope.

CA'VITARIES, *Entozoa cavitaria*. (Lat. cavitas, *a hollow.*) Intestinal worms, or Entozoa, which have an intestinal canal floating in a distinct abdominal cavity.

CAY'MAN, or CAIMAN. A name, says Marcgrave, applied to the crocodiles by the negroes of Congo. According to Bontius it was originally derived from an eastern dialect (*per totam Indiam cayman audit*). It appears, however, that Marcgrave is correct; for the negroes in the West Indies have been heard to call the crocodiles which they have seen there for the first time *caïman;* and the name has been diffused over the new continent by the negroes, and applied to most of the American species indiscriminately. It is restricted by Cuvier to the alligators. *See* ALLIGATOR.

CE'DRELA'CEÆ. (Cedrela, one of the genera.) A very important, though small, natural order of plants, allied to *Meliaceæ*, from which they differ in having winged indefinite seed. Most of the species are trees of large size. *Swietenia mahogani* yields mahogany, in the woods of the Spanish main; *Chloroxylon swietenia*, Indian satin-wood; while the yellow wood and the cedar of New Holland are the produce of others. In general their bark is powerfully astringent; that of *Soymida febrifuga* and mahogany itself is a potent febrifuge; that of *Cedrela toona* is a most valuable tonic in the Malayan archipelago; and *Khaya senegalensis* yields a similar remedy for the dangerous fevers of the Gold Coast.

CE'ILING. (Fr. ceil, *a canopy or covering.*) In Architecture, the upper horizontal or curved surface of an apartment opposite the floor, usually finished with plastered work. In executing ceiling the best mode is that in which the setting coat is composed of putty and plaster, technically called *gauge*. Common ceilings are executed with plaster without hair, the same as the finishing coat in walls left for paper.

CELASTRA'CEÆ. (Celastrus, one of the genera.) A natural order of shrubby Exogens, formerly confounded with *Rhamnaceæ*, but separated by Brown, chiefly because of the relation that the stamens bear to the petals and the different æstivation of the calyx. Allied, according to Brongniart, to *Malpighiaceæ*, through *Hippocrateæ*, a small order which scarcely differs from this order. *Celastraceæ* are natives of the warmer climates, especially of the tropics, and their general characters appear to be of a stimulating acrid nature: none of any popular interest.

CE'LERES. (Lat. celer, *swift.*) In Ancient History, the body of cavalry instituted by Romulus when he settled the constitution of Rome. They consisted of those among the citizens who were rich enough to furnish a horse. They are said to have been 300 in number, and to have been subdivided into three centuries, under the name of Ramnes, Titienses, and Luceres; but this seems to proceed on the false supposition that the three tribes known by these names were among the institutions of Romulus. The number of the centuries of the Celeres was raised to six by Tarquinius Priscus: this was the origin of the Equites or knights, who in after times formed a separate class of citizens.

CE'LIBACY. (Lat. cælebs, *unmarried.*) The legal condition of unmarried persons. This condition was subjected by the laws of the Roman emperors to a variety of penal consequences. The most remarkable of their enactments, and that on which the subsequent jurisprudence on this subject was in a great measure founded, was the *Lex Julia* or *Papia-Poppæa*, enacted under the authorization of Augustus. By these laws unmarried persons could receive nothing by will from strangers, and were subjected to many other legal disabilities (*see* LAW, ROMAN); from which, however, they were successively relieved by later laws passed in the decline of the empire, and especially after the mistaken zeal of the Christian divines of that age had invested celibacy with attributes of sanctity. It was at an early period in the history of the Christian church that ministers were exhorted to celibacy by those who laid claims to a higher degree of sanctity. At the Council of Nice, in A. D. 325, the proposition to enforce it as a general law was rejected. But at that of Arles, in 340, it was adopted; married persons being indeed held admissible into the church, but only on the terms of separating from their wives on ordination. It had become the common practice of the Latin church in the reign of Gregory the Great (end of the 6th century), and was more fully enforced, after a period of relaxation, in the 11th. It was proposed to the Council of Trent by Charles V. (in the interim), that married priests should retain their wives; but this was rejected. In the Greek church, celibacy was ordained for bishops at the council of Tralle, A. D. 695; but clergymen below the degree of episcopacy are allowed to marry. Hence the higher dignities of that church are necessarily filled by monks.

CELL. (Lat. cella.) In Ancient Architecture, the part of a temple within the walls; also called the *naos*. The part of the temple in front of the cell was called the *pronaos*, and that in the rear the *posticum*.

CE'LLAR. (Fr. cellier.) In Architecture, the lower story of a building, when wholly or partly under the level of the ground.

CE'LLEPORES, CELLEPORÆ. (Lat. cella, *a cell;* porus, *a pore.*) A genus of flexible cellular Polyps, including those in which each of the cells is pierced with a minute pore.

CE'LLULAR TISSUE. A substance consisting of little bladders or vesicles of various figures adhering together in masses. It constitutes the principal part of all plants, and may be regarded as an organic basis, into which other kinds of tissue are introduced, or from which they are created. It exists exclusively in the embryo of a plant until vitality has been excited, and new forms of tissue developed in consequence. *See* BOTANY.

CEME'NT. (Lat. cementum.) In Architecture, the medium for causing the adherence of stones or bricks to each other, formed of lime, sand, and water. The best cement is obtained from limestone, in preference to chalk; and the sand best adapted to the formation of it is that of a river, called drift sand.

CEME'NT. In Anatomy, the substance which joins together the plates of compound teeth, like those of the elephant, and which fills up the folds and cavities in the teeth of Ruminants and Pachyderms; and which also covers all that part of a simple tooth which is not coated

with enamel. The cement is characterized, like true bone, by the presence of the Purkinjian corpuscles.

CEMENT, PARKER'S. *See* SEPTARIA.

CEMENTA'TION. When a solid body is surrounded by the powder of other substances, and the whole heated to redness, the process is termed *cementation*. Iron is said to be converted into steel by cementation with charcoal.

CE'METERY. (Gr. κειμαι, *I lie dead*.) In Architecture, an edifice or area where the dead are interred. The most celebrated public cemeteries of Europe are those of Naples, one near Bologna, of Pisa, and the more modern Parisian one of Pere la Chaise. That of Pisa is particularly distinguished by the beauty of its form and architecture, which is early Italian Gothic. It is 490 feet long, 170 feet wide, and 60 feet high, cloistered round the four sides, and contains 50 ship-loads of earth, which the Pisans brought from Jerusalem. It was long matter of complaint and regret that England possessed no public cemeteries; and in the year 1832 a company was formed in London with the view of supplying this desideratum. The land selected for the first experiment contains in extent about 50 acres, and is situated at Kensal Green on the south of the Harrow road. This receptacle for the dead is denominated "All Souls Cemetery;" and whether we regard the good taste or the public spirit displayed by its projectors, it is well entitled to the support of the community. (See the *British Cyclopædia*.) Since that time various cemeteries have been designed and formed in different parts of the country; and there is every ground to believe that, independently of other advantages, the benefits which cannot fail to accrue to the health of large towns, particularly, from schemes of this nature will ultimately lead to their general adoption. In the *Companion to the British Almanac* for 1839, there is an excellent description of the *Norwood* and *Highgate* cemeteries, and some of the previous numbers of the same publication contain an account of all similar works in England then in progress or completed.

CENO'BIO. A term invented by Mirbel to denote a regular fruit, divided from the base into several acephalous pericarpia; that is to say, pericarpia not marked on the summit by the stigmatic scar, the style having been inserted at their base, as in *Labiatæ*, *Boraginaceæ*.

CE'NOTAPH. (Gr. κενος, *empty*, and ταφος, *a sepulchre*.) In Architecture, a monument erected to the memory of a person who lies interred elsewhere.

CE'NSOR. In Ancient History, the title of two Roman magistrates originally created for the purpose of taking the census, or register of the number and property of citizens. But their powers were much increased subsequently, when they had the inspection of the morals of the citizens committed to them, with authority to degrade senators and knights from their respective orders, and remove other citizens from their tribes, depriving them of all their privileges except liberty; which was termed making them Ærarians. They had also the power of making contracts for public buildings and the supply of victims for sacrifices.

The office of censor was not a permanent one, but was renewed from time to time, as its functions were felt to be needed in the state. It was always filled by consulars of the highest merit, and was esteemed an honour even greater than that of the consulate itself: no person might be twice invested with it; and if one of the censors died, another was not substituted in his room, but his surviving colleague was obliged to resign. The office of censor was abolished under the emperors, who, however, exercised the greater part of its functions. It was attempted to be revived in the person of Valerian by Decius, but he was cut off before he could accomplish his purpose.

CE'NSUS. In Ancient History, a population return of the Roman citizens, including a valuation of each man's property, and a registration of his tribe, family, children, and servants.

The secondary senses of the word are, a tax levied according to the above-mentioned valuation; and the amount of any individual's property. A senator's census was the amount of property necessary for a member of the senate, which was equal to between 6000*l*. and 7000*l*. of our money; but this was raised by Augustus to about 10,000*l*. A knight's census was something more than 3000*l*.

The term census, in modern political phraseology, signifies an enumeration of the inhabitants of a country; such as has taken place in England by act of parliament in 1801, 1811, 1821, 1831.

CE'NTAURS. In Greek Mythology, a fabulous race of beings, half man and half horse, who are said to have inhabited part of Thessaly, and waged constant war with the hostile tribe of Lapithæ.

CENTAU'RUS, the CENTAUR. One of the forty-eight ancient constellations formed by Ptolemy, situated in the southern hemisphere, and under the tail of Hydra. The Centaur is represented as half man, half horse; the human part only of the figure is visible above our horizon.

CE'NTERING. (Lat. centrum.) In Architecture, the temporary woodwork or framing on which any vaulted work is constructed; sometimes called also a centre.

CE'NTIGRADE DIVI'SION. The division into *grades* or degrees by hundredth parts. A unit of any denomination being divided into a 100 equal parts, forms a centigrade scale; but the term most frequently occurs in scientific works, in reference to the French division of the scale of the thermometer. The fixed points of the thermometric scale are the points at which water freezes on the one hand, and boils on the other; the distance between these two points being divided into a 100 degrees, the centigrade scale is formed. In Fahrenheit's scale, which is usually applied to the thermometer in this country, the same distance is divided into 180 degrees; a degree of the centigrade scale is therefore greater than a degree of Fahrenheit in the proportion of 180 to 100, or of 9 to 5. Any number of degrees, therefore, on the centigrade scale, being multiplied by 9 and divided by 5, will give the equivalent number of degrees of Fahrenheit. But in comparing temperatures expressed by the two scales, it is necessary to recollect that the zero of Fahrenheit's scale is not placed at the freezing point, but 32° below it. An example will best show how this is to be taken into account. Let it be required to express on Fahrenheit's scale the temperature corresponding to 10° centigrade. Here $10 \times 9 \div 5 = 18$; to this add 32, and we have $18 + 32 = 50$; so that 10 degrees of the centigrade scale correspond to 50 degrees of Fahrenheit's.

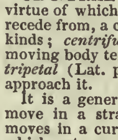
CE'NTIPEDE. (Lat. centum, *a hundred*, and pes, *foot*.) The name of the Myriapodous insects belonging to the genus *Scolopendra* of Linnæus. They are wingless; and the largest species possess, when full grown, more than fifty and less than two hundred pairs of feet.

CE'NTO. (Gr. κεντρων, *a patchwork cloak or garment*.) A word employed to designate a collection of separate verses from the works of one or more poets, arranged so as to form a distinct poem. The only classical example of a cento left to us is that of Ausonius, who composed a nuptial idyll out of Virgilian verses; in which, however, the words are also perverted into a new meaning. In his prologue to this piece Ausonius describes the cento, and gives rules for its composition.

CE'NTRAL FORCE. The power or energy in virtue of which bodies in motion tend to approach, or recede from, a centre. Hence central forces are of two kinds; *centrifugal* (Lat. fugere, *to avoid*), when the moving body tends to recede from the centre; and *centripetal* (Lat. petere, *to seek*), when the body tends to approach it.

It is a general law of matter, that all bodies tend to move in a straight line; consequently, when a body moves in a curve, there must necessarily be some force which acts upon it, and deflects it from the rectilinear direction, and constrains it to move in the curve; and if this force were removed, or its action suspended, the body would immediately fly off in a straight line, forming a tangent to the curve at the point in which it was moving when the force ceased to act. A stone whirled rapidly round the hand in a sling affords a familiar illustration. The effort with which it tends to fly off is the centrifugal force; the reaction of the hand, communicated through the string, may be regarded as a centripetal force, which confines the stone to its circular path. When the string is let slip, the centrifugal force is not counteracted, and the stone flies off in the direction of the tangent.

The laws of central forces, of the greatest importance in the theory of the planetary revolutions, were first proposed by Huygens, in his celebrated work, entitled *Horologium Oscillatorium*. The case which it is most important to analyse is that of a body moving in the circumference of a circle with a uniform velocity. To find an expression for the centrifugal force of a body revolving uniformly in a circle, let $r =$ the radius of the circle, $v =$ the velocity of the body, and let AB be the arc described in the infinitely small time t; we have then (the space described being as the velocity and the time of description) $AB = vt$. But AB being by hypothesis a very small arc, may be considered as equal to its chord, which is a mean proportional between the diameter $2r$, and the versed sine AC. Hence, $AC \cdot 2r = AB^2 = v^2 t^2$, and consequently $AC = \frac{v^2 t^2}{2r}$. Now AC is the effect produced by the central force, or rather the accelerating force exerted in the direction of the centre (that which prevents the body at A from flying off in the direction of the tangent AD), in the time t; and the accelerating force being measured by the quotient which is obtained by dividing twice the space described by the square of the time (*see* DYNAMICS, FORCE), the accelerating force in the direction of the centre becomes $\frac{2AC}{t^2}$. Calling this central force f, and substituting for AC its value, we find $f = \frac{v^2}{r}$; that is to say, the central force of a body describing a circle with a uniform velocity is directly



proportional to the square of the velocity, and inversely as the radius of the circle.

This expression may be put under a different form. Let t = the time required to describe the whole circumference $2\pi r$, and we have $2\pi r = v t$; whence $v = \frac{2\pi r}{t}$ and consequently $f = \frac{4\pi^2}{t^2} r$; whence the central force is directly as the radius of the orbit, and inversely as the square of the periodic time.

If the law of the force be such that its intensity is reciprocally proportional to the square of the distance from the centre, then the squares of the periodic times of two bodies describing different circles about the same centre are proportional to the cubes of the distances. For let F and f be the two forces, V and v the velocities of the two bodies, R and r the radii of their circles, and T and t the times respectively; then, by what has been already shown,

$$F = \frac{V^2}{R},\ f = \frac{v^2}{r};$$

but by hypothesis, $F : f :: r^2 : R^2$;

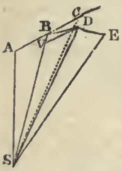
therefore, $\frac{V^2}{R} : \frac{v^2}{r} :: r^2 : R^2$;

but $V^2 : v^2 :: \frac{R^2}{T^2} : \frac{r^2}{t^2}$

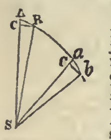
therefore, $T^2 : t^2 :: R^3 : r^3$;

or the squares of the times are as the cubes of the radii. This remarkable property was discovered by Kepler to belong to the planetary orbits. *See* KEPLER'S LAWS.

When a point is urged by one accelerating force only, constantly directed towards a fixed point, the path will be a plane curve, and the areas described around this point by the radius vector are proportional to the times employed in describing them. Suppose the time to be divided into equal portions, and that in the first portion of time the body, in virtue of the projectile force impressed on it, describes the line A B. If no other force acted upon it, in the second portion of time it would describe B C = A B; therefore, on drawing the radii A S, B S, C S, to the centre of force, the triangles A S B and B S C would be equal. But suppose the central force acting on the body while it would move from B to C to act instantaneously at B, so as to cause the body to descend through B V; draw V D parallel and equal to B C, and join B D, then at the end of the second portion of time the body will be at D. Now as the central force acts in the direction B V in the plane of A S B, the body must continue to move in that plane; and on joining C D and S D, the triangle B D S, on account of the parallel lines, is equal to B C S, and therefore equal to A B S. In like manner it may be proved that if E be the point at which the body arrives at the end of the third instant, the triangle D E S is equal to A B S. Suppose, therefore, the number of the triangles to become infinitely great, and their areas infinitely small, the path of the body will become a curve line; and the elementary spaces being proportional to the elements of the time, their sums or integrals must continue to have the same proportion. (*Newton's Principia*, Sect. II.)



From this proposition it follows, that when a body describes a curve in virtue of a central force, the centrifugal force at every point varies as the cube of the distance from the centre, whatever the nature of the force by which it is attracted to the centre may be. For let A B and $a b$ be the two arcs described at different points of the curve in the infinitely small time t, then, by the proposition just demonstrated, A S B = a S b. But make B C and $b c$ respectively perpendicular to S A and S a, then A S B = ½ A S × B C, and a S b = ½ a S × $b c$; hence A S × B C = a S × $b c$, and B C² : $b c^2$ :: a S² : A S². Now B C² = 2 A S × A C (the square of A C being neglected as infinitely small), and $b c^2 = 2 a$S × $a c$; therefore, A S × A C : a S × $a c$ :: a S² : A S², and consequently



$$AC : ac :: \frac{1}{AS^3} : \frac{1}{aS^3}$$

But A C is the measure of the centrifugal force at A, and $a c$ is its measure at a; therefore, denoting the distances at these points by R and r, we have the centrifugal force at A to the centrifugal force at a, as $\frac{1}{R^3} : \frac{1}{r^3}$. Hence we may perceive the reason why a body in moving round a centre of force may alternately approach to, and recede from, that centre, as the planets in describing elliptic orbits about the sun. Suppose the attractive force, like gravity, to vary inversely as the square of the distance from the attracting point: if the planet approached 10 times nearer to the sun, the attractive force would be augmented 100 times; but the centrifugal force would become 1000 times greater, and consequently there must be some point at which this force will overcome the former, and determine the planet again to recede.

The doctrine of central forces has its principal application in astronomy. By the comparison of a great number of planetary observations, Kepler discovered that each of the planets, while its distance from the sun is variable, moves in such a manner that a straight line drawn from it to the sun describes equal areas in equal times. But this is the law by which bodies move under the influence of a central force (as is demonstrated above). It follows, therefore, that the force by which the planets describe their orbits is a central force, and directed to a point within the orbit. Newton demonstrated that the velocities of a body at different points of the curve which it describes about a centre of force, are inversely as the perpendiculars drawn from the centre to the tangents at these points. The comparison of this proposition with the elliptic motion of the planets leads directly to the conclusion that the forces by which the planetary motions are sustained are directed to the centre of the sun, and vary inversely as the squares of the distances of the planets from that body.

Mathematicians have investigated the orbits which bodies must describe under various hypotheses respecting the law of the central force, and they have found that there are only two cases in which a system of bodies like the sun and planets, mutually attracting each other, could permanently exist. One of these is an imaginary case, in which the force varies directly as the distance of the body; the other is the case presented by nature, in which the force follows the inverse ratio of the square of the distance. In all other cases the mutual action of the bodies would produce permanent derangements, which at length would of necessity subvert the system.

When the force varies inversely as the square of the distance, the orbit which is described about a fixed centre must necessarily be one of the three conic sections; but it will depend upon the velocity with which it is at first projected whether the orbit be an ellipse, a parabola, or an hyperbola. If the central force were supposed to vary as the inverse cube of the distance, a body would describe a circle in one particular case, namely, when the velocity of projection is equal to that which would be acquired by falling from an infinite distance, and then applied in a direction at right angles to the radius vector. In all other cases it would describe a spiral. If the central force diminishes more rapidly than the inverse cube of the distance, the orbit would in all cases describe a spiral; so that if the solar force acted according to a law of this sort, every planet would at length either fall into the sun, or fly off to an infinite distance. (*Principia*, Book I. See also *Herschel's Astronomy*, *Cab. Encyc.*)

CE'NTRE. (Lat. centrum.) This term has numerous applications in Geometry and Mechanics: thus, *centre* of a *circle*, or of an *ellipse*, is the middle point of any diameter; *centre* of a *curve* is the point where two diameters intersect each other; and in mechanics we speak of centres of attraction, conversion, equilibrium, gravity, percussion, oscillation, &c.

CE'NTRE OF ATTRACTION, also called *Centre of Gravitation*, is the point to which bodies tend in consequence of the action of gravity.

CE'NTRE OF CONVERSION is the point in a body about which it turns when a force is applied to any part of it, or unequal forces to its different parts. For example, suppose a rod laid on a table to be struck near one extremity in a direction perpendicular to its length; the rod will turn round, but there will be one point in it which remains at rest, or about which, as a centre, the other points turn. This point is the *centre of conversion*.

CE'NTRE OF EQUILIBRIUM of a system of bodies is a point such that if the system were suspended from it, the whole would remain in equilibrium. Thus, the fulcrum or point of support of a lever is its centre of equilibrium.

CE'NTRE OF GRAVITY. A term employed in Mechanics to denote a certain point in the interior of a body, or system of bodies connected with each other in an invariable manner, so situated that any plane whatever which passes through it divides the body into two segments of which the weights are exactly equal. Hence, if the centre of gravity of any body or system of bodies be sustained, the whole will remain at rest; for the weights on both sides of a vertical plane passing through the point of support being equal, the body can have no tendency to angular motion.

Let there be a system of bodies A, B, C, D, E, placed horizontally in the same straight line,

S A B O C D E

and connected with each other in an invariable manner; and suppose O to be the centre of gravity of the system:

by the definition of the centre of gravity, if the system is supported at O, the weights on both sides of O, or the effort which the bodies make to turn about that point on opposite sides of O, will exactly counterbalance each other, and the whole will remain at rest. But the effect of A in turning the system about O depends on the quantity of matter in A, and its distance from O, or the length of the arm of the lever at the extremity of which it acts. The whole effect of the body A is therefore proportional to the mass of A multiplied into the length of the line O A. The same reasoning obviously applies to each of the other bodies, B, C, D, and E; consequently, taking these letters to represent the masses of the bodies respectively, we have, by the definition,

$$A \cdot OA + B \cdot OB = C \cdot OC + D \cdot OD + E \cdot OE.$$

Now suppose it were required to determine from this property the position of the centre of gravity of the united bodies, or its distance from a given point S in the same straight line: on making $SA = a$, $SB = b$, $SC = c$, $SD = d$, $SE = e$, and the unknown distance $SO = x$, we shall have $OA = x - a$, $OB = x - b$, $OC = c - x$, $OD = d - x$, and $OE = e - x$. Therefore by substitution,

$$A(x-a) + B(x-b) = C(c-x) + D(d-x) + E(e-x);$$

and by transposition,

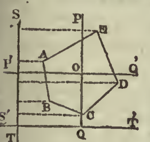
$$(A+B+C+D+E)\,x = aA + bB + cC + dD + eE;$$

whence $x = \dfrac{aA + bB + cC + dD + eE}{A+B+C+D+E}$;

that is to say, the distance of the centre of gravity of the given system from a given point is equal to the sum of the products of all the masses into their distances from the point divided by the sum of the masses.

It is obvious, from the equation now given, that the effect of all the bodies to produce motion about the point S, is the same as if they were all united in their common centre of gravity O. It is also obvious that the form of the equation will be exactly the same, whatever may be the number of bodies belonging to the system; and as every body may be regarded as composed of elementary particles, the reasoning which applies to a system of particles, connected with one another in an invariable manner, also applies to solid bodies of any kind.

The bodies composing the system have been supposed to be arranged in a straight line; but the centre of gravity will be found precisely in the same manner, whatever their relative situations may be. Suppose them to be situated all in the same plane, and that their centre of gravity is O, the position of which it is required to find. Let P Q be any straight line, in the same plane with the bodies, passing through O; then in order that there may be no tendency to motion about the line P Q, the sum of the products of all the bodies on one side of P Q into their respective distances from that line, must be equal to the sum of the products of all the bodies on the other side of P Q into their respective distances. If, therefore, S T be a straight line parallel to P Q, and if the distances of A, B, C, &c. from S T, be denoted respectively by a, b, c, &c., and the distance of O from the same line by x, then we shall have as before,



$$x = \frac{aA + bB + cC + \&c.}{A + B + C + \&c.}$$

This does not yet give us the centre of gravity; but it gives its distance from a given straight line S T, and consequently gives the position of the straight line P Q, in which the centre of gravity is situated. If then we draw another line S′ T′, and denote its distances from A, B, C, &c., by a', b', c', &c., respectively, and put x' equal to its distance O Q from O, we shall have

$$x' = \frac{a'A + b'B + c'C + \&c.}{A + B + C + \&c.};$$

and consequently the position of another straight line P′ Q′ passing through the centre of gravity, and parallel to S′ T′. Therefore, the centre of gravity is given by the intersection of the two straight lines P Q and P′ Q′.

Lastly, suppose the bodies composing the system not to be situated all in the same plane. In this case, the situation of each of the given bodies must be referred to three planes given in position; and it is most convenient to assume three planes which intersect each other at right angles; one of them horizontal, and consequently the other two vertical. Let the distances of the given bodies A, B, C, &c. from the given horizontal plane be respectively a, b, c, &c.; their distances from one of the vertical planes a', b', c', &c.; and from the other, a'', b'', c'', &c.; then, if we take

$$x = \frac{aA + bB + cC + \&c.}{A + B + C + \&c.},$$

the centre of gravity is in a horizontal plane, at the distance x from the given horizontal plane.

Take also $x' = \dfrac{a'A + b'B + c'C + \&c.}{A + B + C + \&c.}$, and the centre of gravity is in a plane parallel to the first of the two given vertical planes, and distant from it by the line x'.

In the intersection of these two planes, take a point distant from the second vertical plane by a quantity $x'' = \dfrac{a''A + b''B + c''C + \&c.}{A + B + C + \&c.}$: this point will be the centre of gravity of the given bodies.

In the notation of the differential calculus, these formulas are expressed as follows:—Let dm be the element of the mass, the co-ordinates of which, referred to three rectangular planes, are x, y, z; and let the distances of the centre of gravity of the mass from the same planes be respectively X, Y, Z; then the position of that centre is determined by the three equations;

$$X = \int \frac{x\,dm}{m},\quad Y = \int \frac{y\,dm}{m},\quad Z = \int \frac{z\,dm}{m}$$

The determination of the centre of gravity of solids in general requires the application of the integral calculus, and is sometimes effected with considerable labour; there are, however, many particular cases in which it is known immediately, and requires no calculation. Thus, the centre of gravity of a sphere or ellipsoid is evidently at the centre of the figure; that of a parallelopiped is at the common intersection of its four diagonals; that of a cylinder with parallel ends at the middle of its axis. The centre of gravity of a circle or ellipse is also at the centre of the figure; and that of a parallelogram at the intersection of its diagonals. The centre of gravity of a straight line is at the middle of the line, whence we easily find that of the perimeter of any polygon. "When the body can be divided into two parts, their common centre of gravity may be found by dividing the distance between the centres of gravity of the two parts in the reciprocal proportion of their weights. This principle may be extended to bodies which are more complex. Thus the centre of gravity of two portions being determined, they may be conceived to be united in that point, and connected with a third portion, and the centre of the three portions found. All these again may be supposed collected in this last point, and made to balance against a fourth portion, and their common centre of gravity computed. In this way the process may by successive steps be carried to any extent, and whatever order is followed the result will be always the same." (*Leslie's Elements of Nat. Phil.*)

The centre of gravity of a triangle is in the straight line drawn from any one of its angles to bisect the opposite side, and at the distance of two thirds of the whole line from the vertex. The centre of gravity of a pyramid is in the straight line drawn from the vertex to the centre of gravity of the base, and at three fourths of the distance of this line from the vertex. The centre of gravity of a hemisphere is in the diameter, and at the distance of five eighths of the radius from the summit.

The centre of gravity of irregular bodies may be found mechanically in various ways. If the body be poised in two different positions on a sharp edge, the vertical drawn from the point of intersection will pass through the centre of gravity. Or if a loose thread or string have its ends fastened to two distinct points of the body, and the body be thus suspended in two different positions from a fixed point, the verticals let fall from this will cross in the centre of gravity.

It is a remarkable property of the centre of gravity, that if a plane figure be generated by the revolution of a given line, or a solid by the revolution of a given plane figure, the area in the first case, or the volume in the second, is equal to the product of the generating quantity into the length of the line described by its centre of gravity. This property, which is frequently of use in determining the quadrature of curves and the cubature of solids, is called *Guldin's theorem;* though it is found in the *Collections of Pappus*.

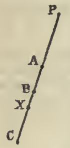
Another elegant geometrical property of the centre of gravity is, that in any given plane the sum of the squares of the distances of any number of physical points from their common centre of gravity, is less than the sum of the squares of their distances from any point in the circumference of a circle described about that centre, by the square of the radius multiplied by the number of those points. Hence it follows that the sum of the squares of the distances of any number of points from their common centre of gravity is always a *minimum*.

For a complete explanation of the method of applying the calculus to the determination of the centre of gravity of bodies, we refer to the *Traité de Mécanique* of Poisson, tom. i. The subject necessarily occupies a part of every work on statics.

Ce′ntre of Gyration of a body, or system of bodies, is a point in which if the whole mass were collected, a force applied at any distance from the axis of suspension would communicate to the mass thus collected the same

angular velocity that it would have communicated to the system in its first condition.

It is evident from the definition that the point in question must have this property, that if the whole mass were united in it, the moment of inertia, or the power of resisting the effort of any force, will be the same as the moment of inertia of the body in its first state. Let,



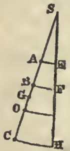
therefore, A, B, and C be a system of bodies, connected in an invariable manner, and turning about an axis P. Let a, b, and c be the respective distances of A, B, and C from P; and conceive X to be another body placed at a distance x from the axis, such that its moment of inertia is equal to the moment of inertia of A. Then, by the principles of mechanics, the moment of inertia of A is $A \cdot a^2$, and that of X is $X \cdot x^2$; therefore, by hypothesis, $X \cdot x^2 = A \cdot a^2$. In like manner, conceive another body Y to be placed at the distance x from the axis, such that its moment of inertia is equal to that of B, or such that $Y \cdot x^2 = B \cdot b^2$; and let a third body Z be placed at the same point, such that $Z \cdot x^2 = C \cdot c^2$. Taking the sums of these equals we have $(X + Y + Z)\, x^2 = A \cdot a^2 + B \cdot b^2 + C \cdot c^2$. Now in this equation we are at liberty to give either to $X + Y + Z$ or to x any value we please. Let us then suppose $X + Y + Z = A + B + C$ (which is evidently the same as supposing all the matter in the system united at the point whose distance is x), and we shall have

$$x = \left(\frac{A \cdot a^2 + B \cdot b^2 + C \cdot c^2}{A + B + C}\right)^{\frac{1}{2}}$$

to express the distance of the centre of gyration from the axis.

Centre of Oscillation is that point in a body, oscillating about a fixed axis, into which if the whole mass were collected, the body would vibrate through a given angle by the force of gravity in the same time as in its first condition.

In order to find the point having this property, conceive the weights A, B, and C fixed to a slender inflexible rod, vibrating about the point S, the



centre of oscillation being at O. In every position of the system, the tangents to the arcs which the bodies respectively describe make equal angles with the horizon; consequently the bodies are all urged by the same proportion of the total force of gravity. But if the bodies had not been connected with each other, their descent through similar arcs, A E, B F, C H, in the same interval of time, would require the accelerating forces to be proportional to those arcs, or to SA, SB, S C. Let S O, therefore, represent the accelerating force at O; then A O and B O will denote the excess of the force by which A and B are respectively accelerated, and C O the excess of the force by which C is retarded. But the effects of these forces on the motion of the system must be proportional to the weights of the bodies; and by the principles of the lever, they must also be proportional to the respective distances of the bodies from the point of suspension. They are consequently represented by $A \cdot SA \cdot AO$, $B \cdot SB \cdot BO$, and $C \cdot SC \cdot CO$. But the accelerating action at the centre O must necessarily be equal to that of retardation; consequently $A \cdot SA \cdot AO + B \cdot SB \cdot BO = C \cdot SC \cdot CO$. Now let $SA = a$, $SB = b$, $SC = c$, and $SO = f$, and the equation becomes by substitution $A \cdot a\,(f - a) + B \cdot b\,(f - b) = C \cdot c\,(c - f)$, or $(A \cdot a + B \cdot b + C \cdot c)\, f = A \cdot a^2 + B \cdot b^2 + C \cdot c^2$; whence

$$f = \frac{A \cdot a^2 + B \cdot b^2 + C \cdot c^2}{A \cdot a + B \cdot b + C \cdot c};$$

that is to say, the distance of the centre of oscillation from the point of suspension, or the length of the simple pendulum which vibrates in the same time with the compound body, is found by taking the sum of the products of the weights into the squares of their distances from the axis of the pendulum, and dividing this sum by the sum of the products of the weights into their distances simply.

Though the system has here been supposed to be formed of separate bodies, the principle is universal, and applies to bodies of any form. Let dm represent an element of the body, and x its distances from the point of suspension, then $f = \dfrac{\int x^2\, dm}{\int x\ \, dm}$.

It may be remarked, that the denominator $A \cdot a + B \cdot b + C \cdot c$ is equal to $(A + B + C) \cdot SG$, the point G being the centre of gravity of the bodies. Now if we denote the distances of A, B, and C from the centre of gravity G by α, β, γ respectively, and make $SG = h$, we shall have $a = h - \alpha$, $b = h - \beta$, and $c = h + \gamma$; whence by involution and substituting in the numerator, and observing that $A\alpha + B\beta - C\gamma = 0$, we shall find $A \cdot a^2 + B \cdot b^2 + C \cdot c^2 = h^2(A + B + C) + A \cdot \alpha^2 + B \cdot \beta^2 + C \cdot \gamma^2$; therefore, since $OG = SO - SG = f - h$,

$$OG = \frac{A \cdot \alpha^2 + B \cdot \beta^2 + C \cdot \gamma^2}{(A + B + C)\, SG},$$

an equation which gives the distance of the centre of oscillation from the centre of gravity.

This last equation indicates a very remarkable property of the centre of oscillation. As the two quantities O G and S G may change places without disturbing the equality, it follows that the centre of oscillation and the point of suspension are interchangeable; in other words, if the system were suspended from O, it would vibrate exactly in the same time as when suspended from S. This property was noticed by Huygens, and was first practically applied to the purpose of finding the length of the seconds' pendulum by Captain Kater. The application is made as follows: — Let a bar of iron, for example, about four feet long, be suspended from a point A, at the distance of four or five inches from one of its extremities, and observe the number of vibrations it makes in a given time. Then suspend it from another point B, near its other extremity, and let the point of suspension B be moved backwards or forwards till it makes exactly the same number of vibrations in a given time as when suspended from A. Then the distance between A and B is the length of the isochronous simple pendulum.

On comparing the three expressions for the centre of gravity, the centre of gyration, and the centre of oscillation, it will be seen that the distance of the centre of gyration from the axis is a mean proportional between the distances of the centres of gravity and oscillation.

The method of determining the centre of oscillation of compound pendulums was first given by Huygens in his celebrated work *Horologium Oscillatorium.* His demonstration, however, was founded on an indirect principle, which was rather assumed than proved. It consists in this, that if several weights attached in any manner to an inflexible rod or pendulum descend by the action of gravity, and if at any instant they were detached or disengaged from each other, each of them, in virtue of the velocity it had acquired during its descent, would mount to such a height that the common centre of gravity of all of them would reach exactly the same height as that from which it descended. The first direct demonstration on the principle of the lever was given by James Bernoulli, in the *Memoirs of the Academy of Sciences of Paris* for 1703. An interesting history of this problem may be found in the first volume of *Lagrange's Mécanique Analytique.*

Ce'ntre of Percussion. The point in a solid body, or system of bodies, into which, if the whole matter were supposed to be collected, the effect produced by striking against another body would be the greatest possible; or it may be defined to be the point in the axis of a moving body at which, if stopped by an immoveable obstacle, the body would rest in equilibrio, without inclining to either side, or acting on the centre of suspension.

When the percutient body revolves about a fixed axis, the centre of percussion is at the same point with the centre of oscillation; but when it moves with a parallel motion, the centre of percussion is the same as the centre of gravity.

Ce'ntre of Pressure, of a fluid against a surface, is that point at which if a force were applied equal to the pressure, and acting in an opposite direction, the surface would remain at rest.

Ce'ntre of Rotation. The point about which a body circulates. It is the same as the centre of motion.

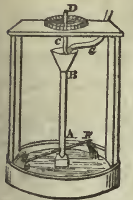
Ce'ntre of Spontaneous Rotation. The name first applied by John Bernoulli to the point about which a body, all whose parts are at liberty to move, and which has been struck in a direction not passing through the centre of gravity, begins to turn.

CENTRI'FUGAL. (Lat. centrum, and fugio, *I retreat.*) A term employed in describing the inflorescence of plants, when, in a head of flowers, the central one opens first, and those of the circumference last. It is also used by carpologists in describing seeds when the apex of an embryo is turned away from the centre of a fruit.

CENTRI'FUGAL FORCE. The force by which a body in rotation tends to recede from the centre of motion: Centripetal Force, that by which a body in motion is urged towards a centre, and compelled to describe a curve instead of a straight line. *See* Central Force.

CENTRI'FUGAL MACHI'NE. A machine moved by the centrifugal force of water; frequently called, from its inventor, *Barker's Mill.* It consists of a hollow metal cylinder or pipe of metal placed upright, and resting on a pointed steel pivot at A. The pipe is widened or extended into a funnel shape at the top B, and is kept in its position by a vertical steel axis C D, passing through a frame at the top. Towards the lower extremity, two or more small pipes A E, A F, with closed external ends, are inserted at right angles to the axis. In the side of

each of these an orifice is made as near as possible to the end, and on opposite sides, so that water from them may spout horizontally in opposite directions. Water is conveyed into the funnel at the top, through the pipe G, in such quantities that the tube is kept constantly full, while the discharge is going on at the orifice near the extremities of the horizontal pipes. In this state of things the resistance or reaction generated by the water issuing from the side holes is such as to throw the vertical pipe, with its arms and axis, into rapid rotatory motion; and this axis may communicate its motion or power to wheel-work or machinery, or to a mill-stone connected with its upper end. (See *Library of Useful Knowledge*, "Treatise on Hydraulics;" also *Ferguson's Lectures*, by Brewster; or *Lardner's Cabinet Cyclopedia*, "Hydrostatics and Pneumatics.") A machine of the same construction, but having the arms at the upper end, and turned rapidly by means of a wheel and pinion, was invented by a Mr. Erskine for raising water. Centrifugal Machine is also used synonymously with *Whirling Machine*.



CE'NTRING. *See* CENTERING.

CENTRI'PETAL. (Lat. centrum, and peto, *I seek.*) A term employed in describing the inflorescence of plants, when, in the unfolding of a head of flowers, those at the circumference open first, and those in the centre last. It is also used by carpologists in describing seeds when the apex of an embryo is directed towards the centre of a fruit.

CENTRI'SCUS. (Gr. κεντρις, *a spine.*) A genus of Acanthopterygious fishes, having the foremost dorsal placed far backwards, and with its first spine remarkable for its length and strength; the mouth is slender and elongated, whence they have obtained the name of "sea-snipes."

CE'NTRUM. (Gr. κεντρον, *centre.*) A term applied by Fries technically to designate the typical division of the groups of species and genera, in his circular arrangement of *Fungi*. Many generic names are compounded, having this word for their root, as *Centrogaster*, *Centrolophus*, *Centropristis*, and *Centronotus*, all genera of spiny-finned fishes; *Centropus*, a genus of birds, allied to the Cuckoos, &c.

CENTU'MVIRI. In Ancient History, Roman judges chosen three from each of the thirty-five tribes, so that properly there were 105; but they were called *centumviri*, or the hundred, from the round number. The principal causes that came under them were those concerning testaments and inheritances. In the time of Augustus they formed the council of the prætor; but afterwards their number was increased to 180, and they were divided into four councils, which, however, were sometimes combined into two courts, or even into one. Ten persons (*decemviri*) were appointed, five senators and five equites, to assemble these councils and preside in them in the absence of the prætor.

CE'NTURIES. (Lat. centuriæ.) In Ancient History, the divisions in which the Roman people voted at the Comitia Centuriata. They were instituted by Servius Tullius for the purpose of throwing political power into the hands of the plebeians. The patricians were represented by six centuries of knights, and twelve centuries of knights were added to these from the plebeians. The rest of the plebeians and clients were divided into five classes, according to the amount of their property; the lower limits of each being respectively 100,000, 75,000, 50,000, 25,000, 12,500 asses. The first of these classes was subdivided into eighty centuries; the next three into twenty each; and the last into thirty. The centuries of each class were again separated into two equal numbers of old and young. By this distribution the preponderance was given to property, though the rich classes were of course outnumbered by the poorer. Besides these centuries there were divisions in other bodies that went by the same name, as in the army half a maniple was called a century.

CENTU'RION. In Ancient History, an officer in the Roman army, who had the command of half a maniple, or one sixtieth part of a legion. The word centurion signifies the commander of 100 men; but this number was in fact seldom complete, as the legion generally fell far short of its full complement. One of the two centurions of each maniple had a precedence before the other; and the centurion of the first century of the first maniple of the Triarians presided over all the others, and had the charge of the eagle or chief standard of the legion, which gave him the privilege of ranking with the knights. The badge of a centurion was a vine rod.

CEPHALA'NTHIUM. (Gr. κεφαλη, *the head*, and ανθος, *a flower.*) A term invented by Richard to express the head or capitate inflorescence of a composite plant.

CEPHA'LIC. (Gr. κεφαλη, *the head.*) Medicines used for the relief of diseases of the head are frequently termed *cephalic remedies*.

CEPHALI'TIS. Inflammation of the brain.

CEPHALO'DIUM. (Gr. κεφαλη, *a head.*) In Botany, a term used by systematic writers on lichens, and signifying the figure of a convex shield without an elevated rim: it is called also a tuberculum.

CE'PHALO'PHORA. (Gr. κεφαλη, *the head*, and φερω, *I bear.*) A name substituted by De Blainville in his system of Malacology for the "Cephalopoda" of Cuvier.

CEPHA'LOPODS, *Cephalopoda*. (Gr. κεφαλη, *the head*, and πους, *the foot.*) A class of Molluscous animals having the head situated between the body and the feet; these latter organs consist of a number of fleshy processes, which project forwards from the circumference of the head, and more or less conceal the mouth. The Cephalopods are the first class of *Mollusca* in the system of Cuvier, and the most highly organized of invertebrate animals. They alone present indubitable rudiments of an internal skeleton, developed for the purpose of protecting a brain and lodging organs of sight, and, in most of the existing species, organs of hearing. In these also there are distinct hearts both for the systemic and pulmonary circulations; and highly complicated digestive, secretory, respiratory, and generative organs. The sexes are in distinct individuals. All the species are marine. The principal features of the organization of this class of Invertebrata are described by Aristotle, and their habits were better understood by that ancient author than by modern naturalists of the present day. The Cephalopods are described and grouped together in the *Historia Animalium*, under the name of "Malakia."

CE'PHALOTA'CEÆ. (Cephalotus, the only genus.) A small natural order of Exogens, allied, according to Labillardiere, to *Rosaceæ*, according to Brown to *Francoaceæ* and *Crassulaceæ*. Its affinity appears, however, to be greater with *Dionea* than with the previous orders. It consists of a single species, with pitcher-like bodies mixed with its leaves; it is a marsh plant inhabiting New Holland.

CE'PHALO-THO'RAX. (Gr. κεφαλη, *the head*, and θωραξ, *the chest.*) The first segment of Arachnidans and Crustaceans, which includes the head and thorax of insects.

CE'POLA. (Der. unknown.) The name of a genus of spiny-finned fishes, including the common riband-fish (*Cepola rubescens*) of our coasts.

CERA'CEUS. (Lat. cera, *wax.*) In Botany, waxy. Applied to the substance of such bodies as have the texture and colour of new wax, as the pollen masses of particular kinds of Orchis.

CE'RAMBY'CIDÆ. A family of Capricorn beetles, characterized by antennæ generally exceeding the length of the body; a large and distinct labium; strong horny mandibles; maxillæ terminated by two distinct hairy lobes; eyes kidney-shaped, with the antennæ situated in the concavity; body generally long and narrow. The numerous insects of this vegetable-feeding family are arranged in many subgenera, of which the following are indigenous: *Acanthocinus*, *Aphelocnemia*, *Callidium*, *Cerambyx*, *Clytus*, *Lamia*, *Molorchus*, *Monochamus*, *Obrium*, *Pogonocherus*, *Saperda*, and *Stenopterus*. One of the most remarkable species of our country is the musk-beetle (*Cerambyx moschatus* of Linnæus, *Callichroma* of Latreille), which, when alive, disseminates an odour resembling sometimes that of the otto of roses.

CE'RASIN. Cherry-tree gum. A generic name given to those kinds of gum which swell and soften, but do not readily dissolve in water.

CERA'STES. (Gr. κερας, *a horn.*) The name of a genus of poisonous serpents, characterized by having a pointed recurved horny process standing up over each eye: the horned vipers, as they are termed, are peculiar to Africa.

CE'RATE. (Gr. κηρος, or Lat. cera, *wax.*) An ointment generally compounded of wax and oil or spermaceti.

CERA'TIUM. (Gr. κερας, *a horn.*) A one-celled, many-seeded, superior linear fruit; dehiscent by two valves separating from the replum; the seeds attached to two spongy placentæ adhering to the replum, and alternate with the lobes of the stigma. It differs from the Siliqua in the lobes of the stigma being alternate with the placenta, not opposite.

CE'RATOPHYLLA'CEÆ. (Ceratophyllum, the only genus.) A small natural order of Exogens, allied, according to Richard, to *Coniferæ*, but to which it seems to have no kind of affinity. According to De Candolle it should be placed near *Hippuris* and *Myriophyllum*, from which it differs in its superior ovary; according to Agarh it belongs to *Fluviales*: its affinity, however, appears to be greatest with *Urticaceæ*, of which it may be regarded as a degeneration. The order consists but of one genus, which is found in the ditches of Europe, being constantly submerged, and floating with its long green leaves after the manner of a Conferva. The

embryo appears to be decidedly Polycotyledonous; otherwise the plant would certainly be referred to *Naiadaceæ*.

CERATO'PHYTES, *Ceratophyta*. (Gr. κεϱας, *a horn*, and φυτον, *a plant*.) A name applied by Cuvier to a family of Corticiferous Polyps, comprehending those in which the internal axis resembles horn or wood.

CE'RATRIN. The bitter principle of Iceland moss.

CE'RBERUS. In Mythology, a monster usually represented as the guardian of the entrance to the infernal regions, and described by the ancient authors as possessing three, fifty, or even a hundred heads.

CERCA'RIÆ. (Gr. κεϱκος, *a tail*.) A family of Infusoria, having an enlarged body with a slender tail-like appendage. The body of the true *Cercariæ* of vegetable Infusiores is rounded, that of the Zoosperms or animalcules of the seminal secretion is flattened. *See* Zoospermes.

CERCO'PIDÆ. *See* Cicadellans.

CE'RCOPITHE'CUS. (Gr. κεϱκος, *a tail*, and πιθηκος, *an ape*.) The name of the genus of Quadrumanes, including those which have long tails, but not prehensile; or the "monkeys" of the old world.

CERE. (Lat. cera, *wax*.) In Ornithology, the naked and generally coloured skin which covers the base of the bill in some birds, as in those of the hawk tribe (*Falconidæ*).

CE'REAL GRASSES. (Lat. ceres, *corn*.) Grasses which produce the bread corns; such as wheat, rye, barley, oats, maize, rice, and millet.

CEREBE'LLUM. (Lat. dim. of cerebrum, *the brain*.) The little brain; the posterior of the medullary masses which compose the brain of vertebrate animals. It is a single organ. *See* Brain.

CERE'BRUM. (Lat.) The third medullary mass of the brain, counting from behind forwards: it is divided in the mesial line into two lateral lobes or hemispheres, and is the only part of the cerebral organ whose development bears relation to the intelligence of the species.

CEREMO'NIAL OF EUROPEAN POWERS, comprises—1. The particular titles due to sovereigns in different states; the imperial title being considered as expressing some sort of superiority over the royal, and having been in consequence assumed by various kings in their public acts (as the King of England since the union of the crowns). 2. The acknowledgment of sovereign titles, the right to confer which was formerly claimed by the Popes as their own prerogative, but they are now assumed by princes, and confirmed by the acknowledgment of other sovereigns. 3. The respective prerogatives of different sovereigns; which species of precedence is that which has occasioned the greatest amount of discussion and dispute when sovereigns, or their representatives, have been brought together. In 1504, Pope Julius II. arranged the rank of European powers in the following order: 1. The Roman Emperor; 2. The King of Rome; 3. France; 4. Castile; 5. Aragon; 6. Portugal; 7. England; 8. Sicily; 9. Scotland; 10. Hungary; 11. Navarre; 12. Cyprus; 13. Bohemia; 14. Poland; 15. Denmark; 16. Republic of Venice; 17. Duke of Britanny; 18. Burgundy; 19. Elector of Bavaria; 20. Saxony; 21. Brandenburg; 22. Archduke of Austria; 23. Duke of Savoy; 24. Grand Duke of Florence; 25. Duke of Milan; 26. Bavaria; 27. Lorraine. This arrangement, however, gave birth to repeated contests. At present, where precedence is not considered as established between rulers of equal dignity, each concedes to the other precedence at home; and when they meet on the territory of a third party, they take precedence alternately until some arrangement is effected

CE'REMONIES, MASTER OF THE. An officer of the king's household instituted by James I. for the more honourable reception of ambassadors and strangers of quality: it is his duty to attend and regulate all matters of etiquette in the drawing room and the levee, and on all occasions where the state of a court is to be maintained.

CEREO'PSIS. The generic name of an Australian goose, characterized by a green cere-like naked membrane covering the upper parts of the base of the bill. It has bred frequently in this country, and there is every probability that it will ultimately become naturalized.

CE'RES. One of the four new or telescopic planets which revolve between the orbits of Mars and Jupiter. It was discovered by Piazzi on the 1st of January, 1801. Ceres is a very small planet, its apparent diameter, according to Schroeter, being only 3·48″, which at its mean distance corresponds to about 1600 miles; but according to Sir W. Herschel its apparent diameter is only 0·35″, or 160 miles. The difficulty of distinguishing its real disk, on account of the nebulosity by which it is surrounded, accounts for the discrepancy. Its mean distance from the sun is rather more than three times the distance of the sun from the earth. *See* Planet.

Ce'res. In Mythology, the Latin goddess corresponding to the Grecian Demeter (Δημήτηϱ), was the patroness of tillage. She was the daughter of Saturn and Rhea, and, by Jupiter, mother of Proserpine. The most remarkable thing connected with this goddess was the celebration of the Eleusinian mysteries, over which she presided.

CE'REUS. (Lat. cera, *wax*.) In Botany, a colour, surface, or texture which resembles that of wax.

CE'RIN. The portion of wax which dissolves in boiling alcohol. Also a peculiar waxy substance obtained by boiling grated cork in alcohol.

CERI'NTHIANS. Followers of Cerinthus, a heretic of the first or second century, who embraced certain gnostical views respecting the natures and relations of God the Father and Son. He conceived the supreme God to be the father or originator both of the Deity from whom proceeded the O. Test. and of Christ; that the God of the Jews was also the creator of this world; and that his dominion over it was superseded by the mission of Christ, who was a son of the supreme Deity residing in a human body. *See* Gnostics.

CE'RIO. A term invented by Murleel to denote the fruit called a Caryopsis, which see.

CE'RITE. A silicious oxide of cerium.

CE'RIUM. A metal named after the planet Ceres, and discovered in 1803 by Hisinger and Berzelius in a Swedish mineral termed *cerite*, and since found by Dr. Thomson in *Allanite*, a mineral from Greenland. It is said to be a white brittle metal, very difficult of fusion, and volatile when intensely heated; but we are scarcely acquainted with it in its metallic state. Its equivalent number appears to be 48, on the hydrogen scale.

CE'RINUS. (Lat. cera, *wax*.) In Botany, waxy yellow; a term used in describing colour, to denote a dull yellow with a slight mixture of reddish brown.

CERO'MA. (Gr. κήϱωμα.) In Ancient Architecture, the apartment in a bath or gymnasium in which persons anointed themselves with a composition of oil and wax.

CEROPLA'STIC. (Gr. κηϱος, *wax*, and πλαστικη τεχνη, *the art of the modeller or carver*.) The art of modelling in wax, one of very high antiquity. From the testimony of Pliny we learn that Lysistratus, the brother of Lysippus, was the first that used wax for modelling the human figure. He lived in the time of Alexander the Great, and was a native of Sicyon.

CEROSTRO'TUM, or CESTRO'TUM. (Gr. κηϱος, *wax*, and στϱωτος, *spread*.) A species of encaustic painting, executed chiefly on horn or ivory with a particular sort of stylum called a cestrum, which was pointed at one end and flat on the other. The cestrum was heated, and with it the lines of the subject were burnt in, and wax introduced into the furrows made by the heated instrument. (See *Pliny*, lib. xi. cap. 37., also lib. xvi. cap. 48.; also *Salmas. ad Solin.* p. 231.) Doors were sometimes ornamented with this species of painting. *Ausonius*, Epigr. 26. v. 10.—

Ceris inurens januarum limina,
Et atriorum pegmata.

CE'RTHIA. (Gr. κεϱθεις, part. of κειϱω, *I clip or shear*.) A genus of Anisodactyle or uneven-toed Tenuirostral or slender-billed Passerine birds, commonly known by the name of Creepers. The common tree-creeper (*Certhia familiaris*, Linn.) is a well-known native species.

CE'RTIORA'RI. In Law, is an original writ issuing out of Chancery or the King's Bench, directed to the judges or officers of inferior courts, commanding them to *certify* or return the records of a cause depending before them. By this writ indictments and many other proceedings may be removed from any inferior court of jurisdiction into the King's Bench. It lies generally in all judicial proceedings in which a writ of error does not lie; but not, in common cases, to remove a cause out of an inferior court after verdict.

CE'RULIN. Indigo which has been dissolved in sulphuric acid.

CERU'MEN. (Lat. cera, *wax*.) The secretion which lines the external auditory canal. It consists of albumen, an oily matter, a colouring matter, soda, and phosphate of lime.

CE'RUSE. (Lat. cerussa.) Carbonate of lead, the basis of white oil-paint. It is commonly called *white lead*.

CERVI'NUS. (Lat. cervus, *a stag*.) In Botany, fawn-coloured.

CE'RVIX. (Literally the lower part of the neck.) An obsolete botanical term, superseded by that of *Rhizoma*, which see.

CE'SSIO BONO'RUM. In the Civil Law (and in the modern jurisprudence of France, Spain, Holland, and Scotland), a yielding up on the part of an insolvent trader of his estate and effects to creditors, under the authority of the competent court; analogous to the assignment of estate and effects under a fiat in bankruptcy in England. See as to the several regulations respecting the *cessio bonorum* in these different countries, *Burge's Commentaries on Colonial and Foreign Laws*, iii. 890. &c.

CE'STOI'DEANS, Cestoidea. (Gr. κεστὸς, *embroidered*, and ειδος, *likeness; riband-like*.) The name of an order of Sterelmintha, or Parenchymatous Entozoa, including those which are commonly called tape-worms.

CESTRA'CEÆ. (Cestrum, one of the genera.) In Botany, a very small group of plants, most usually combined with *Solanaceæ*, but by some botanists separated on account of their straight embryo, foliaceous cotyledons, and valvate corolla. Some of the species have fragrant flowers, especially at night; others emit an unpleasant odour. Some are astringent, others are said to be poisonous.

CESTRA'CION. (Gr. κεστρεαιος, *the name of a fish.*) In Ichthyology, a genus of sharks, characterized by having two kinds of teeth, disposed in oblique subspiral rows; those at the anterior part of the jaws are pointed, and adapted for seizing or grappling shell-fish, &c.; those at the middle and back part of the jaws are flattened for crushing the same: the fishes of this genus are also remarkable for the large spine placed in front of the first dorsal fin. Only two existing species of this genus are known, one of which is called "the Port Jackson shark;" the fossil remains of Cestracions are numerous.

CE'STRUM. (Lat.) In Painting, a tool used by the ancients in executing the species of pictures called *cerostroti*. *See* CEROSTROTUM.

CETA'CEANS, *Cetacea*. (Gr. κητος, *a whale.*) An order of Mammals living in the sea or large rivers, and shaped like fishes for moving habitually in the watery element, having the posterior part of the spine disencumbered of a sacrum and hinder extremities to allow the tail to have a due freedom and extent of motion. They breathe air, have warm blood, and a double circulation, like the rest of the class to which they belong; they are consequently compelled to resort to the surface for the purpose of respiration; and the tail-fin is accordingly horizontal, and not vertical, as in true fishes.

CE'TE. (Gr. κητος, *a whale.*) The name of the sixth order of Mammalia in the *Systemæ Naturæ* of Linnæus, containing those marine species which are devoid of hinder extremities. The group corresponds with the carnivorous group of the modern *Cetacea*, the manatee being associated in the Linnæan system with the elephant.

CE'TIC ACID. The result of the action of alkalis upon *cetine*.

CE'TINE. Pure spermaceti.

CE'TUS. (Gr. κητος, *the whale.*) One of Ptolemy's forty-eight constellations, in the southern hemisphere.

CEVA'DIC ACID. An acid contained in the seed of the *Veratrum sabadilla*.

CEVADI'LLA. *See* SABADILLA.

CE'YLANITE. A mineral found in rounded grains or small crystals, nearly opaque, and of a dark blue or black colour; it was first observed in the sand of the rivers of Ceylon.

CHABA'SIE. A variety of zeolite. (From a Greek word signifying a particular kind of stone.)

CHACO'NE, or CIACONE. (Spanish.) In Music, a kind of dance resembling a saraband, of Moorish origin. The bass of it consists of four notes, which proceed in conjoint degrees, whereon the harmonies are made with the same burden. Some have derived this dance from *cieco*, a blind man, its supposed inventor.

CHAFF. The husk or withered calyx of grasses, and more especially of the bread corns. The term is also applied to straw or hay cut into very short lengths, and used for mixing with corn, roots, or other food for horses or cattle. This kind of chaff, in greater lengths, is also used for mixing with mortar on some parts of the Continent, more particularly in Germany and Russia; and it is used as a substitute for hair in making plaster for rooms. Both stubble and cut hay were used by the ancient Egyptians in making bricks.

CHAFF OF THE RECEPTACLE. A term used by some botanists to denote the bracts which are stationed upon the receptacle of Composite flowers, between the florets; they have generally a membranous texture, and no colour, and are usually called Paleæ.

CHA'FFY, PALEACEOUS. When a surface is covered with small, weak, erect membranous scales, resembling the chaff of corn, as the receptacle of many Composite plants.

CHAI'LLETIA'CEÆ. (Chailletia, one of the genera.) A natural order of shrubby arborescent Exogens, placed by De Candolle between *Homaliaceæ* and *Aquilariaceæ*; agreeing with the former in the presence of glands round the ovary, but differing in its superior ovary, with the placenta in the axis, and in many other characters. Its affinity, however, appears to be greatest with *Rhamnaceæ*, with which it agrees in habit. It inhabits the hotter parts of the world, and some species are said to be poisonous.

CHALA'ZA. (Gr. χαλαζα, in the sense of *a knob.*) In Botany, the vascular disk caused by the expansion of the vessels of the raphe, upon reaching the base of the nucleus of an ovule, after passing up the side of the latter.

CHALA'ZÆ. (Gr. χαλαζα, *hail.*) A name applied to the two membranous twisted chords attached to near the poles of the yolk of an egg, and serving to maintain it in such a position that the cicatricula shall always be uppermost, and consequently nearest the source of heat during the process of incubation.

CHALCE'DONY. A semitransparent silicious mineral, apparently formed by the infiltration of silicious matters originally in a state of solution. It is of various colours, and often banded. The finest specimens are said to have been originally found at Chalcedon in Asia.

CHALCI'DICUM. (Lat.) In Ancient Architecture, according to Festus so named from Chalcis, a city in Eubœa. A term used by Vitruvius to denote a large building appropriated to the purpose of administering justice, or according to others the tribunal itself.

CHALCO'GRAPHY. (Gr. χαλκος, *brass*, and γραφω, *I write.*) The art of engraving on copper or brass.

CHA'LDRON. (Lat. chaldarium; Fr. chaudron, whence also cauldron.) A measure containing 36 bushels heaped measure.

CHALK. (Germ. kalk.) Earthy carbonate of lime. It forms an important geological feature of this country, the chalk hills which form the white cliffs of our shores having conferred the name of ALBION upon the island. Geologically considered, it is an important feature among the secondary rocks. The cretaceous formation is characterized by peculiar fossils, and especially by containing *flints*. The ranges of chalk hills in the south of England are very extensive, and the landscape which they constitute peculiar for the smooth and rounded outline of its hills, their monotony of surface, and the singular cup-shaped concavities and deep hollows in which their sides abound. Between Dunstable and Shaftesbury the chalk hills attain an elevation of nearly 1000 feet above the level of the sea. Between Lewes in Sussex and Alton in Hampshire there are several similar elevations.

CHALK STONES. The concretions formed in the joints of persons who have long suffered from gout were once supposed of a chalky nature, and acquired the above name. They are chiefly composed of uric acid in combination with soda.

CHA'LLENGE. In Law, an exception to jurors who are returned to serve on a trial. *See* JURY.

CHALY'BEATE. (Gr. χαλυψ.) The Chalybes were a Scythian people who dug iron. Medicines and mineral waters containing iron are called *chalybeates*.

CHA'MA. (Gr. χαω, *I gape.*) The cockle.

CHAMA'CEANS. (Lat. chamacea.) In Conchology, the family of Acephalous Lamellibranchiate Mollusks, of which the genus *Chama*, or clam-shells, is the type. The group is characterized among bivalves by having the mantle perforated by three apertures; one for the passage of the foot, another for the respiratory currents, and a third for the escape of the excrements.

CHAMÆ'LEON, *Chameleo*. (Gr. χαμαιλεων, *a lizard.*) A genus of Saurian reptiles with small tubercular scales, and the tail and feet organized for clinging to the branches of trees. The chameleons subsist not on air, as poets feign and the uninformed believe, but on flies and other insects, which are caught by means of a remarkably long and extensible tongue, terminated by a finger-shaped process like the elephant's proboscis, and which the chameleon can dart upon its prey with great rapidity. The rete mucosum or coloured layer of the skin contains two kinds of pigment, situated in different layers; the deeper seated layer is of a deep green or violet red colour, the superficial pigment is of a greyish colour; the deep-seated pigment is contained in branched cavities, and is moveable, producing by its partial accumulation and varying proportions with the superficial layer the changes of colour for which the chameleon has in all ages been remarkable.

CHAMÆ'LEON MINERAL. A compound of manganesic acid and potash, which presents a variety of tints when dissolved in water.

CHA'MBER. (Fr. chambre.) In Architecture, properly a room vaulted or arched; but now generally used in a more restricted sense to mean an apartment appropriated to lodging. With the French the word has a much more extensive meaning; but with us the almost only use of it, beyond what is above stated, is as applied in a palace to the room in which the sovereign receives the subject, which is called the Presence Chamber.

CHA'MBERLAIN. (Fr. chambellan; Germ. kammerherr.) A high officer in all European courts. Originally the chamberlain was the keeper of the treasure-chamber (camera, in the 10th century); and this meaning of the word is still preserved, in the usages of corporations of London and other places, where the chamberlain is the officer who keeps the money belonging to the municipal body. But, in modern times, the court officer styled chamberlain has the charge of the private apartments of the sovereign or noble to whom he is attached. In England, the lord great chamberlain, or king's chamberlain, is one of the three great officers of the king's household. He has the control of all the officers above stairs, except the precinct of the king's bedchamber, which is under the government of the groom of the stole.

Under him are the vice-chamberlain, lord of the bedchamber, &c.; the chaplains, officers of the wardrobe, physicians, tradesmen, artizans, and others retained in his majesty's service are in his department, and sworn into office by him. He is commonly one of the highest nobility of the country; in virtue of his situation he precedes dukes. The emblem of office appropriated to the chamberlain in European courts is a gold key, generally suspended from two gold buttons.

The LORD GREAT CHAMBERLAIN OF ENGLAND (not of the household) is the sixth great officer of state. This office belonged for many centuries to the noble family of De Vere, Earls of Oxford; afterward to that of Bertie, Lords Willoughby de Eresby and Dukes of Ancaster. In that line it became vested in coheiresses, by whom the present deputy chamberlain (Lord Gwydir) is appointed.

CHA'MBRE ARDENTE. In French History, a name given to the tribunal which was instituted by Francis I. for the purpose of trying and burning heretics; and also the extraordinary commissions established under Louis XIV. for the examination of prisoners, and under the regent Duke of Orleans against public officers charged with certain offences against the revenues, and those guilty of fraud in the matter of Law's bank.

CHA'MBRE DES COMPTES. (Chamber of Accounts.) In French History, a great court established for various purposes; as for the registration of edicts, ordinances, letters patent, treaties of peace, &c. The sovereign chambre des comptes was at Paris: there were also inferior courts in ten provincial cities.

CHA'MFER. (Fr. chamfrein.) In Architecture, the edge of anything originally right-angled cut aslope or bevel, so that the plane it then forms is inclined less than a right angle to the other planes with which it intersects.

CHA'MOMILE FLOWERS. The flower-heads of the *Anthemis nobilis*, or common chamomile. They are used in medicine in consequence of their bitter extract, which is strengthening, and of their essential oil, which is aromatic and stimulant.

CHAMP DE MARS. In French History, the public assemblies of the Franks, which were held in the open air, and annually in the month of March; from whence the name. Under Pepin and some of his successors they were termed Champs de Mai. An extensive open space in Paris, appropriated to various public solemnities, is termed the Champ de Mars; a name which seems also intended to recall the ancient Campus Martius, or public field of Rome.

CHA'MPERTY. In Law, is a species of maintenance, being a bargain with the plaintiff or defendant in a suit for the "campi partitio," or division of the land or thing in dispute between the party, if he prevails at law, and the champerter, on the latter's bearing the expense of the suit. It is a punishable offence both by common law and by statute.

CHA'MPION. (From the Italian campione, derived from campo, *field;* or from the ancient German and Gothic kempe, kiempe, *a warrior;* whence some have derived also the Spanish campeador, a title of the *Cid.*) One who fights a public combat, or engages to do so, in his own or another man's quarrel. On the issue in a writ of right trial by battle might formerly be demanded; and in this case (*see* WAGER OF BATTLE), each party appeared in the field by his champion. The judicial combat in criminal cases might in some countries, although not in England, be fought by a champion for either of the parties, if an ecclesiastic, woman, or child. The office of champion of the crown of England is of great antiquity; the manor of Scrivelsby in Lincolnshire having been held from time immemorial in grand serjeantcy, on condition that the lord thereof shall be the king's champion. This manor was long held by the family of Marmion; it passed, in the 20th year of Edward I., to the family of Dymocke, in which it has since continued. The champion appears in Westminster Hall at the coronation, between the courses of the royal banquet, in complete armour; his challenge is proclaimed by the herald, waging battle with any person who shall deny or gainsay the title of the king, three times; and the champion throws down his gauntlet. In 1821, at the coronation of George IV., it was decided that this office could be performed by deputy; and W. Dymocke being in orders, his place was supplied by his eldest son.

CHANCE. A term applied to events that are supposed to happen without any known or necessary cause; or rather, of which the cause is such that they may happen in one way as well as another. Thus, when a piece of money is tossed up into the air, as no reason can be given why it should fall on one side rather than on the other, it is said to be an even chance which of the sides shall turn up. For an account of this branch of mathematics, sometimes called the *Doctrine of Chances*, see PROBABILITY.

CHA'NCEL. (Lat. cancellus.) In Architecture, the part of the choir of a church between the altar and the lattices (cancelli) or balustrades that enclose it. This is the strict meaning; but in many cases the chancel extends much further into the church, the original divisions having been removed for the greater accommodation of the congregation.

CHA'NCELLOR. (Lat. cancellarius.) A high officer in many European states. The cancellarius under the Roman emperors is supposed to have been a notary or scribe, and his title to have been derived from the cancelli or railing behind which he sate. In ecclesiastical matters, every bishop had (and continues to have) his chancellor, the principal judge of his consistory. The chancellor of France began to be an officer of importance under the Frankish kings, especially after the office of referendary had become merged in his, about the ninth century. In 1223 he was made the first minister of the crown, and rank next after the princes of the blood was assigned to him. The offices of chancellor and keeper of the seals were frequently united.

CHANCELLOR, ARCH, OF THE EMPIRE. This office, under the elective empire of Germany, belonged to the archbishop elector of Mentz. The archbishop of Cologne was titular arch-chancellor of Italy, the archbishop of Treves of Gaul and Arles.

CHANCELLOR OF A DIOCESE. The keeper of the seals of an archbishop or bishop. This office now includes those of official principal, whose duty is to hear and decide matters of temporal cognizance determinable in the bishop's court; and vicar-general, who exercises the jurisdiction properly spiritual.

CHANCELLOR OF THE EXCHEQUER. The highest finance minister of the British government. This office is from its nature necessarily entrusted to a commoner, and is commonly united to that of first lord of the treasury when the premier happens to be below the peerage. The chancellor, as an officer of the Court of Exchequer, has precedence above the barons of that court.

CHANCELLOR OF A UNIVERSITY. The head of the corporate bodies by whom he is elected. He exercises exclusive jurisdiction in all civil actions and suits where a member of the university or privileged person is one of the parties, except in cases where the right to freehold is concerned. The duties of the respective chancellors of Oxford and Cambridge are in nearly all cases discharged by a vice-chancellor.

CHANCELLOR, CHANCERY. The office of chancellor is the most ancient as well as the highest of all judicial offices in the kingdom; for though the superior antiquity of his jurisdiction has been questioned, the establishment of the office itself was certainly prior to the institution of any existing court of justice, the name as well as some of the functions, which were borrowed from the "cancellarii" of the later Roman emperors, having been introduced into this country within the first three centuries that followed the dissolution of the Western Empire.

In addition to his judicial functions, which are various and extensive, the chancellor is now by virtue of his office privy councillor, and when a peer speaker of the House of Lords; over all the members of which, with the exception of the archbishop of Canterbury, he then has precedence in rank. As chief conservator of the peace, he has the nomination of all magistrates throughout the kingdom; and he is the patron of all livings of the crown under the value of twenty marks in the king's books. He has also the right of appointment to almost all the offices in the Court of Chancery, particularly to the office of master; and has very great influence over the appointment of any of the other judges both of common law and equity. He still retains also the title of keeper of the king's conscience, a duty originally incident to his situation in the king's chapel, over the service of which he presided; and this office may perhaps have afforded a ground for that part of his jurisdiction which professes to remedy what is contrary to equity and good conscience. It is further his duty to issue the writs for the convocation of parliament; and all acts there passed, as well as many records and documents affecting the rights of individuals, — as to the latter in order to their validity, — are enrolled and kept in chancery, under the immediate care and custody of the master of the rolls, himself an officer of that court. The custody of the great seal is the peculiar and essential mark of the chancellor's dignity; and by delivery of that and the proper oaths taken the office is created, with all such of its rights as can be exercised by a chancellor not being a peer.

The jurisdiction of the chancellor is of various sorts. And, first, as to his common law jurisdiction. By this is meant that part of the chancellor's jurisdiction which is regulated by the same principles, and exercised according to similar forms, as the jurisdiction of the other courts of common law. This is by far the most ancient branch of the chancery judicature, and seems to have been originally incident to the nature of the chancellor's office, whose chief business it was to advise the sovereign on the subject of grants, charters, and letters patent, and to

authenticate them by affixing the great seal after the introduction of that symbol. Out of this naturally arose a jurisdiction in all matters between the crown and its grantees, and the right to repeal or cancel all grants, charters, and letters patent, which should afterwards appear to be contrary to law, or in other respects improperly obtained. In like manner the chancellor had jurisdiction in other matters arising out of commissions under the great seal; such as returns made in pursuance of inquiries under such commissions as to the right of the crown to goods or lands of the subject either by escheat, forfeiture, or any other cause; these were legally called offices.

To the same court also belonged originally, in the time of feudal tenures, jurisdiction in the case of wardship, and some other matters arising out of such tenures between the crown and its tenants in capite; but it should be observed, that as this court has not the power of summoning a jury, it can in no case try an issue of fact. It is called the Court of the Petty Bag, literally from the size of the bag in which its writs are deposited. To the common law department of chancery belongs also the issuing of original writs; that is to say, precepts addressed to the party complained of, stating the nature of the complaint made against him, requiring him to do justice to it, or show cause to the contrary; such writs being originally the first and a necessary step in all causes which were tried before either of the three great courts, or in the "aula regia," before its division into separate courts.

In this department of his office the chancellor was assisted by officers named cursitors, whom he was empowered to nominate for that purpose, and upon whom the whole business of devising writs soon devolved. The chancery has hence been called Officina Brevium, or workshop of writs; and is, or was, in respect of the necessity of such writs, the foundation or fountain head of all justice; but this necessity, which had in practice long been satisfied by a fiction, has been in terms dispensed with by the 2d W. IV. c. 39. The receptacle in which these writs were kept was called the Hanaper, — literally a basket; and hence the office from which they issued was called the Hanaper Office.

But by far the most extensive as well as most important branch of the chancellor's jurisdiction is the equitable; indeed, it is that branch alone which is commonly meant by the term chancery. In this department of his office the chancellor is assisted by the master of the rolls and the vice-chancellor; the first of which is a very ancient office, and the second was established by act of parliament in the 53rd year of George III.; who, though they each sit in separate courts, and exercise their jurisdiction severally, yet together with the lord chancellor constitute one court of chancery, in which all orders and decrees, though most commonly made either by the master of the rolls or the vice-chancellor, require the signature of the chancellor himself, to whom an appeal also lies from the decisions of either of the two inferior judges; but such appeals are in strictness of speech rehearings, the chancellor being by legal fiction supposed to be present in every department of the Court of Chancery. The hearing of such appeals, and of incidental applications, called motions, in original causes, constitutes the ordinary business of the lord chancellor, it not being the usual practice to bring causes in the first instance before him.

The general object and character of this equitable jurisdiction is to supply, in civil matters, the deficiencies of the other courts of justice, whether those deficiencies consist in the imperfections of the machinery of those courts, or in their too rigid adherence to peculiar forms, whereby certain classes of rights become excluded from the benefit of their protection. The origin of this equitable jurisdiction is generally sought for in that remnant of judicial power which is alleged to have been left in that part of the "aula regia" which was not included in either of its subdivisions (*see* King's Bench, Common Pleas), and of which residuary part the chancellor was certainly, since the suppression of the office of justiciary, the principal member, and was thus easily enabled to assume whatever judicial power was left undelegated to the other courts. That such remnant of power was adequate to all purposes to which it was moulded, is inferred from the supreme and comprehensive nature of the "aula regia" itself, which must be supposed to have been invested originally with full power to do complete and perfect justice, and of which the remnant therefore still retained an undefined measure of authority sufficient to supply what should prove, on experience, to be wanting in the other courts. This view of the subject is strengthened by the fact that the Court of Exchequer, which was not a part of the aula regia, but a collateral and equal court, or rather perhaps the aula regia in a different shape, has also its equitable jurisdiction, as if that were a necessary part of all complete systems of judicature. Possibly also the idea of paramount and universal authority annexed to the right of framing writs in all actions, or, in other words, of devising remedies for every species of wrong, may have laid the foundation in theory for this supplemental code, as it was certainly the discovery of a new writ, or a new application of an old one, which practically enabled the chancellors to carry their equitable views into effect.

This was the writ of subpœna: a writ returnable in chancery, and calling upon the person to whom it was directed to appeal there, and answer upon oath the complaint that was made against him. The invention of this writ is attributed to John Waltham, Bishop of Salisbury, who was chancellor in the reign of Richard II.; and it is upon the power thereby acquired that rests even now the equitable jurisdiction of the chancery.

Similar in principle to this is the equitable jurisdiction of the Court of Exchequer; which is concurrent with that of the Court of Chancery in all matters of equitable relief, though it can only be called into action by a fiction stated in the pleadings, and which it is not allowable to deny — that the plaintiff is a debtor of the crown, and will by deprivation of the right for which the suit is brought be less able to satisfy such debt. Wherever, therefore, in the course of this or other articles the words *equity* or *courts of equity* occur, they must be taken as applying to the principles and jurisdiction as well of the Exchequer as of the Chancery.

The usual division of the objects of equitable jurisdiction is into Trust, Fraud, Accident, Agreement, and Account.

As courts of equity take into their consideration a far greater variety of circumstances than do courts of law, and as evidence of no fact not suggested by the pleadings is admissible, the written pleadings are necessarily more copious and important than they are at law; and there is further this most essential difference, that the pleadings on the part of the defendant, *i. e.* his answer, are upon oath. With regard to evidence the same general rules prevail in equity as in law, as to the admissibility of proofs, the relevancy of facts, and the competency of witnesses, and even the propriety of the questions that may be put; but the manner of taking evidence is different, for with few exceptions, and those as to very simple facts, evidence in equity is taken either under a commission to examine, or by the official examiners in London, and is produced before the court in a written shape. Where special applications are made during a cause for something to be done in that cause, or, as may sometimes be done, when applications for an order of the court are made without instituting a suit, the evidence adduced is by affidavit. The hearing of such applications, which is either upon written *petition* or by motion upon written notice, constitutes a great part of the business of the court. Evidence of facts not essential in the first instance to the interposition of the court, is usually taken in the master's office upon a reference made to him. The Court of Chancery has also jurisdiction in the guardianship of infants and the management of charities; and the lord chancellor personally has, by special delegation from the crown, jurisdiction in the case of lunatics, which is exercised according to the forms of the old common law jurisdiction of the court upon commission issued.

The appellate jurisdiction of the chancellor in bankruptcy is stated under that title.

CHANCE-MEDLEY. (A corruption of the French *chaude mclée*.) In Law, signified originally a casual affray or riot, accompanied with violence, but without deliberation or preconceived malice; but is applied at present to a particular kind of homicide, — viz. the killing of another in self-defence in a sudden encounter, without *malice prépense*.

CHANGE OF SEED. In Agriculture, the practice of procuring seed produced in a different soil and climate from that in which it is to be grown as a crop; and which is found to be sometimes beneficial, and sometimes injurious, according as the new seed may have been matured in a better or worse climate and soil than those in which it is to be grown.

CHA'NNELS OF A SHIP. Strong narrow platforms of thick plank, projecting from the outside of the ship, abreast each mast, to extend the shrouds, and thereby increase the support of the rigging.

CHANT. (Fr. chanter, *to sing*.) In Music, an ecclesiastical song usually adapted to the psalms and litanies. There have been several sorts, of which the first was the Ambrosian, invented by St. Ambrose, bishop of Milan. The Gregorian chant, which was introduced by Pope Gregory, is still in use in the Roman church, and is the foundation of all that is grand and elevated in music.

CHA'NTRY. (Lat. cantaria.) A little chapel or altar, commonly in some church, endowed (before the Reformation) with revenues for the maintenance of a priest to perform prayers for the soul of the founder and others. Chantries were dissolved in England by 1 Ed. 6. c. 14.

CHA'PEL. (Lat. capella.) In Architecture, a building for religious worship, erected separately from a

church, and served by a chaplain. In Catholic churches and Protestant cathedrals, chapels are usually annexed in the recesses on the sides of the aisles; these are also called chantries.

Chapel. (Fr. chapelle.) In Printing, is the junction of the workmen in an office for the purpose of promoting and enforcing order and regularity in the business, the preservation of the materials, the arrangement of the price of any doubtful work, and the care of the lights. These objects are accomplished by fines.

Moxon, who published his work on printing in 1683, says, "every *Printing-house* is, by the custom of time out of mind, called a *chappel*." It is supposed that the term originated from the circumstance of Caxton, on the introduction of the art into England, practising it in a chapel attached to Westminster Abbey.

The president is termed "the father of the chapel," and is elected; the workmen are styled "members of the chapel;" and this association takes cognizance of all offences, real or imaginary, committed within the office, and punishes the offender by inflicting a fine in proportion to the offence. The process of calling a chapel is by giving the father a halfpenny and desiring him to summon a chapel, stating to him the object; the father then directs the youngest journeyman to announce to all the members the time when it will be held; when the subject is discussed, and the decision taken by vote.

It is an axiom that the chapel is always right, consequently there is no appeal from its decision, and to dispute this would subject the party to its displeasure. It has various ways of enforcing obedience to its dictates.

Chapel. A place of divine worship, either connected with a private establishment, as a nobleman's house, a college, &c.; or subsidiary to a parish church for the sake of additional accommodation (in which case it is called a chapel of ease); or a meeting-house belonging to a Dissenting congregation.

CHA'PLAIN. (Lat. capellanus.) Properly the minister of a chapel. The privilege which the king and nobility enjoy of appointing private chaplains arises from the ancient custom of using domestic chapels for family worship. The limitations under which this privilege may be exercised are set forth in certain statutes of Henry VIII. Under the existing law a nobleman's chaplain may hold two benefices; but the chaplain of a judge, &c. only one: on which, however, he is not obliged to reside.

CHA'PLET. (Ital. ciappelletto.) A string of beads used by Roman Catholics to count the number of their prayers; these prayers consist for the most part of Ave Marias, Paternosters, and Credos. Another name for the chaplet is Rosary. The invention of the practice is generally attributed to St. Dominic.

Chaplet. (Fr. chapelet.) In Architecture, a moulding carved into beads, olives, and the like.

CHA'PTER. (Lat. capitulus; from caput, *head*.) The society of canons in a cathedral or collegiate church, of which the dean is the head, which forms the council of the bishop, and in which his election rested before Henry VIII.; since whom the power of the chapter in this particular (in the English church) has become merely nominal. *See* art. Bishop.

CHA'PTER-HOUSE. (Lat. capitulum.) In Architecture, the apartment (usually attached) of a cathedral or collegiate church in which the heads of the church or the chapter meet to transact business.

CHARA'CEÆ. (Chara, one of the genera.) A natural order of Acrogens entirely destitute of a vascular system, and composed almost exclusively of tubes; placed by Linnæus near to Lichens and to Phænogamous plants; by Jussieu and De Candolle, with *Naiadaceæ;* by Brown, at the end of *Hydrocharaceæ;* by Leman, to *Halorageæ;* by Von Martius, Agardh, and Wallroth, to *Confervæ;* and finally admitted as a distinct order by Richard, Kunth, De Candolle, Adolphe Brogniart, Greville, Hooker, and others: consists of but two genera, which inhabit the fresh and salt waters of most countries. They are remarkable for the distinctness with which the rotation of their fluids may be seen under the microscope. In the opinion of some Italian writers, the insalubrity of the neighbourhood of Rome is owing to the great quantity of chara which inhabits all the pools, and renders them intolerably offensive.

CHA'RACTER. (Gr. χαρακτηρ.) In the Fine Arts, a distinctive property or mark by which any object is separated from another. In physics as in morals, and also in the fine arts, there are three species of character; Essential, Distinctive or Accidental, and Relative. *Essential character* is that type stamped by nature on all her works; that great indication observable in the general divisions of the three kingdoms of nature; those distinctions of different classes of beings, of sexes and ages; in short, of all those great external marks which prevent the confusion of one species with another. *Distinctive* or *accidental character* is that dependent on particular circumstances; on all those varieties of development which a vast number of visible or invisible causes stamp on the same species, according to the difference of their position; as on individuals of the same species, according to the difference of the elements which modify their forms and the influences which some actions may have upon them. *Relative character* is a more particular indication of certain faculties relative to the different properties with which nature has endowed certain species or individuals, in which may be recognized the purposes to which they are more especially destined. In morals *essential character* consists in that uniformity of general habits which forms the peculiar instinct of each species of beings, and which indicates uniformly their inclinations, their predominating tastes, and those propensities which can never be changed by accidental causes. *Distinctive character* is that which peculiar habits of organization, circumstances, social institutions, and all those exceptions which in the very order of nature become suitable to an individual or one of the same species, being in fact but a modification of essential character. *Relative character* is the impression or development in a particular manner of certain qualities suited to a certain end, or to a certain mode of existence, indicating to what purposes the beings in question are suited, and manifesting a co-relation between what the species appears and that for which it is adapted.

The arts are and indeed can be but the result of nature in all countries, of the nations that inhabit them, and of the individuals of which a nation is composed. Nature influences nations, nations men, and men the arts. These are governed either mediately or immediately by an influence more or less dependent on the great natural causes of climate, government, and education, which constitute the essential character of every country; on secondary and political causes, in which nations differ; and on particular causes, which modify individuals. The arts do but imitate this process: according to the particular spot in which they spring up, their imitation embraces either nature in general or parts of nature; either material forms and the sensible images of things, or the moral affections and intellectual ideas of things; but of whatever kind the imitation be, to whatever object it may be directed, the arts are but the faithful mirrors which reflect in every country the physical and moral qualities of nature, of nations, and of the individuals of which the latter are composed. Before judging, therefore, of the imitation, it becomes necessary to judge of the model; and before we can ascertain in what the character of the arts consists, we must know on what its character depends in nature. We have been thus particular in giving some general notions of character, which must be felt before we can be qualified to judge of the character of the arts in any country. The character peculiar to himself which an artist imparts to his work is but a modification of the foregoing principles: more easily, perhaps, may be understood that distinctive character which a work of art requires that it may seem proper and suitable to its end. That character which marks species was well understood by the ancients; and if we may trust Martial, Phidias excelled in catching it. Of his fishes the poet says, "Adde aquam, natabunt."

CHARACTERI'STIC OF A LOGARITHM. The same as index or exponent; meaning the figure prefixed to the logarithm, or preceding the point, and which indicates the integer places or figures in the number to which the logarithm corresponds.

CHA'RACTERS. (Gr. χαρακτηρ, *a mark*.) In Music, the conventional forms in musical writing and printing used for the signs of clefs, notes, rests, &c.

CHARA'DE. (Fr.) A species of riddle, the subject of which is a name or a word that is proposed for solution from an enigmatical description of its several syllables taken separately as so many individual words, and then from a similar description of the whole name or word. A charade can only be called complete if the different enigmas which it contains are brought into a proper relation to each other, and as a whole unite in an epigrammatic point. The following charade, which we borrow from the *Dictionnaire de l'Academie Française*, may be regarded as a good specimen of this species of riddle:—"My first makes use of my second to eat my whole;" the solution being *chien-dent* or dog's grass. The word *charade*, like the term *calembourg* (quod vide), has been applied to this sort of amusement, from the name of its inventor.

CHARA'DRIUS. (Lat.) A bird mentioned by Pliny. The name of a very interesting genus of wading birds, or *Grallatores*, including the British plover and allied species. In modern Ornithology, the Linnæan genus which included the long-legged plover (*Himantopus*), the stone curlew (*Œdicnemus*), and other species is raised to the rank of a family called *Charadriadæ*.

CHA'RCOAL. A form of carbon, obtained by burning wood with the imperfect access of air, or by heating or distilling it in iron cylinders so constructed as to allow of the collection of the volatile products; among which are *tar*, and *pyroligneous acid*, which is impure vinegar. Charcoal, exclusive of its important use as a fuel, is

possessed of some curious and valuable properties. It is a very bad conductor of heat; and hence powdered charcoal is used to surround tubes and vessels which are required to retain their heat. It is not injured by air and moisture; hence stakes and piles are superficially charred to preserve them. It is infusible; and provided air be carefully excluded, it undergoes no change in most intense heats. It absorbs air and moisture, and also the colouring and odoriferous parts of many animal and vegetable substances. Tainted flesh and putrid water are thus sweetened by the action of powdered charcoal, especially by what is called *animal charcoal*, obtained by burning bone, or the clippings of hides, leather, &c. Coloured vegetable solutions filtered through well burned charcoal are materially decoloured by it: when burned in oxygen or air, it is converted into *carbonic acid*. (*See* DIAMOND and CARBON.) Common charcoal intended merely for fuel is prepared by cutting pieces of wood from 1 in. to 3 in. in diameter into lengths of from 1 ft. to 3 ft., forming them into a conical pile, and covering them with turf or clay; leaving two or three small holes, close to the ground, for lighting the wood and boring through the turf in the upper part of the cone, a few other small holes for the escape of the smoke. The pile being lighted at the several holes along the bottom, continues burning with a slow smouldering flame for a week or two, and is allowed to cool before the turf is removed. In the case of very high winds, the holes to the windward are stopped, to prevent combustion from going on with too great rapidity. Charcoal obtained by distilling beech-wood, log-wood, willow, and other woods which are free from resin, is called *cylinder charcoal*. The charcoal employed in the manufacture of gunpowder is now always so prepared.

CHARDS. The footstalks and midrib of artichokes, cardoons, and the white beet are so called. In the case of the artichoke and cardoon, the leaves are tied up, and the light excluded by straw ropes or by soil, in order to blanch the chard, and deprive it of its natural bitterness; after which, when dressed, it becomes an agreeable vegetable. The leaves of the white beet, not being naturally bitter, do not require blanching to render them fit for use.

CHA'RFRON, or CHAMP-FREIN. In Plate-armour, plates of steel or pieces of leather, to protect the face of a horse.

CHARGE. In Gunnery, is the quantity of powder and weight of ball with which guns are loaded. For proving cannon, the charge of powder is equal to the weight of the ball; but for service it is about one half, or more frequently about one third the weight of the ball. Dr. Hutton in his Mathematical Dictionary states that different charges of powder, with the same weight of ball, produce different velocities in the ball, which are in the sub-duplicate ratios of the weight of powder; and when the weight of powder is the same, and the ball varied, the velocity produced is in the reciprocal sub-duplicate ratio of the weight of the ball; which is agreeable both to theory and practice. He states also, that from many experiments made by him on this subject, he found the length of the charge producing the greatest velocity in guns of various lengths of bore, from 15 to 40 calibers, to be as follows:—

Length of bore in calibers.	Length of charge for greatest velocity.
15	3-16ths.
20	3-12ths.
30	3-16ths.
40	3-20ths.

CHARGE. In Heraldry, signifies the various bearings, *i.e.* ordinaries and figures, depicted on the escutcheon. A shield is said to be *charged* with the bearings depicted on it; and so is an ordinary or other charge, when it bears another device upon it.

CHARGE and OVERCHARGE. In Painting, a term applied to any exaggeration of character, expression from colour, &c.

CHARGE' D'AFFAIRES. The third or lowest class of foreign ministers, according to the regulations adopted at the congress of Vienna.

CHA'RITY, SISTERS OF. The name by which an institution of females is known in France, whose office is to attend the sick, and who form a similar society to that of the Beguins in Flanders. *See* BEGUINS.

CHA'RLES'S WAIN. A name sometimes given by astronomical writers to the constellation Ursa Major, or Great Bear. It has sometimes also been applied to the Little Bear.

CHA'RLOCK. A common name in the northern counties for one of the most common weeds, *Raphanus raphanistrum*. The plants when young are remarkably like those of the common turnip; but they are easily distinguished by the taste, which is hot and bitter; while that of the turnip is mild. Cold wet lands are more subject to the charlock than warm calcareous soils. As sheep are remarkably fond of the plant, they are frequently turned into corn fields where it abounds, in which case it is found that they do not touch the corn while any of the charlock remains. That excellent husbandman Mr. Lisle, having sown charlock seed and turnip seed at the same time, found that the latter came up in three days, while the charlock required ten. The seed, when buried in the soil to a certain depth, will retain its vital properties for an unknown length of time; grass lands that have not been ploughed within the memory of man having, when broken up, produced abundance of this plant.

CHA'RON. (Gr. χάρων.) In Mythology, the ferryman of hell, who conducted the souls of the departed in a boat across the Stygian lake to receive judgment from Œacus, Rhadamanthus, and Minos, the judges of the infernal regions. He received an obolus from every passenger, for which reason the ancients used to put that piece of money in the mouths of the dead. He was said to be the son of Erebus and Night.

CHA'RRED WOOD. Wood, the outer surface of which has been carbonized by burning, in order to preserve it from decay when it is buried in the soil.

CHA'RRING OF POSTS. The practice of carbonizing by burning that portion of the surface of wooden posts which is to be inserted in the ground. The object is to prevent the posts from decaying, more especially at the surface of the ground, or, as the common phrase is, between wind and water. The practice is common in most parts of Europe, and even in Russia and Sweden, though timber is there so abundant.

CHART. A hydrographic map for the use of navigators, being a projection of some part of a coast on a plane surface. Charts as well as ordinary maps may be constructed on any of the principles by which a spherical surface is represented on a plane; but they are generally laid down according to Mercator's projection, in which the meridians, and consequently also the parallels of latitude, are represented by parallel straight lines, the degrees of longitude on all the parallels being equal to those of the equator, and the degrees of latitude being increased from the equator towards the pole, so as to bear always the same ratio to the degrees of longitude which they do on the sphere itself. *See* MAP and PROJECTION.

CHARTA'CEUS. (Lat. charta, *paper*.) Papery; indicating the paper-like texture and substance of most leaves.

CHA'RTA, MA'GNA, in English History. The "Great Charter of the Realm" was signed by King John in 1215, and confirmed by his successor Henry III. It is reported to have been chiefly drawn up by the Earl of Pembroke and Stephen Langton, Archbishop of Canterbury. Its most important articles are those which provide that no freeman shall be taken or imprisoned or proceeded against, "except by the lawful judgment of his peers or by the law of the land," and that no scutage or aid should be imposed in the kingdom (except certain feudal dues from tenants of the crown) unless by the common council of the kingdom. The remaining and greater part of it is directed against abuses of the king's power as feudal superior.

CHARTE. (Lat. charta, *paper*.) In French History, originally used to indicate the rights and privileges granted by the French kings to various towns and communities; but applied at present to the fundamental law of the French monarchy, as established on the restoration of Louis XVIII. in 1814. The *Charte* consists of 69 articles, and is founded on principles analogous to those of the British constitution, as embodied originally in the Magna Charta, and subsequently extended in the Bill of Rights. As is well known, it was the violation of an article of the *Charte* by the Ministers of Charles X. that led to the revolution of 1830, the expulsion of that monarch from the throne, and the establishment of the present dynasty. Since that time the *Charte* has undergone a few modifications, the chief of which consists in the abolition of the hereditary peerage. (See the *Almanac Royal et National*, published annually.)

CHA'RTER-PARTY. (Fr. parti, *divided*.) In Mercantile Law, is defined to be a contract, by which the owner or master of a ship hires or lets the whole or a principal part of it to a freighter for the conveyance of goods, under certain specified conditions, on a determined voyage to one or more places. A charter-party is generally under seal; but a printed or written instrument signed by the parties, called a memorandum of a charter-party, is binding if no charter-party be executed. A voyage may be performed in part under a charter-party, and in part under a parol agreement; but the terms of a charter-party cannot be altered by parol evidence, although they may be explained by mercantile usage. The instrument expresses the freight to be paid, and generally, but not necessarily, the burden of the ship; together with some usual covenants, and others at the discretion of the parties.

CHA'RTULARY. In Diplomatics, a collection of the charters belonging to a church or religious house.

CHASE. (Fr. chassis.) In Printing, an iron frame six tenths of an inch in thickness, in which pages are wedged up to secure the letters from separating or dropping out in the process of printing. Chases are of

different dimensions, according to the number of pages in a sheet, and the size of the paper: in the printing of books there are two bars fixed across at right angles, called crosses, so as to divide the chase into quarters for greater security. The thickness is always the same, however large the chase, being lower than the types, for the purpose of keeping the margin of the paper clean.

CHASE. A row or rank of plants or trees, and more especially of hedge plants; also an extent of waste or forest land.

CHASE. In Nautical language, pursuit; also the vessel pursued.

CHA'SER. The vessel pursuing. Also guns at the head and stern for firing when in chase.

CHA'SING, or ENCHASING. In Sculpture, the art of embossing or making bassi rillevi in metals. The work is punched out from the back, and then cut on steel blocks or puncheons, and cleared with small chisels and gravers.

CHAT-POTA'TOES. Small potatoes, only fit for giving to pigs or boiling for poultry.

CHAT-WOOD. Small sticks and spray, only fit for fuel.

CHAU'NTRY. *See* CHAPEL.

CHAYA ROOT. The root of the *Oldenlandia umbellata*, cultivated upon the Coromandel coast as a red dye stuff.

CHEESE. The curd of milk compressed into solid masses of different sizes and shapes; and, when intended for keeping, salted and dried, and sometimes coloured and flavoured. It is almost always made from the milk of cows, but occasionally from that of ewes, and sometimes, though very rarely, from the milk of goats. The following are the principal British cheeses: — *Brickbat*, formed of new milk and cream, chiefly in Wiltshire, in the autumn, and sold in little square pieces about the size of brickbats. *Cheddar*, round thick cheeses, weighing about 150 or 200 pounds, with a spongy appearance, and the eyes or vesicles filled with a rich oil. *Cheshire*, large round thick cheeses, commonly weighing from 100 to 200 pounds each; solid, homogeneous, and dry and friable rather than viscid. They are made from the whole of the milk and cream; the morning's milk being mixed with that of the preceding evening previously warmed. *Derbyshire*, is a small white rich cheese. *Dunlop*, originally made in Ayrshire, but now general throughout Scotland, is large, round, white, buttery, and weighs from 30 to 60 pounds. This and the Derbyshire cheese are very much alike in form, colour, and flavour. *Gloucester*, large, round, and mild; buttery rather than friable. There are two kinds, the single and double Gloucester; the single is made of the milk deprived of about half the cream, and the double of the milk with the whole of the cream. *Green* or *Sage* cheese may be made of any of the other kinds, by mixing the milk before it has curdled with a decoction of sage leaves, among which some put a few flowers of marigold and leaves of parsley. In the Highlands of Scotland the leaves or seeds of lovage are added to the sage, which communicate a very strong flavour. *Lincolnshire* is made of new milk and cream; it is quite soft, not above 2 inches thick, and will not keep more than two or three months. *Norfolk*, the weight is generally from 30 to 50 pounds; the curd is dyed yellow with arnotto or saffron; and though not a rich cheese, it is considered a good keeper. *Soft* or *Slip-coat* is a small soft rich cheese, which might almost be mistaken for butter, if it were not white, and which must be eaten in a week or two after making. *Stilton*, so named from the town in Huntingdonshire where it was first brought into notice, but which is made principally in Leicestershire. It is solid, rich, buttery, and white; and, unlike all the other cheeses which have been mentioned, it is twice as high as it is broad. It is much improved by keeping, and is seldom used before it is two years old. It is the dearest of all English cheeses, the price being generally to that of Chester as 2 to 1, or 2 to 1¼. In order to induce premature decay and the consequent appearance of age in these cheeses, it is said the makers sometimes bury them in masses of fermenting straw. *Cottenham*, so named from a town in Cambridgeshire; it differs chiefly from the cream cheese of Stilton in being flat, broader, and superiorly flavoured. The flavour is said to be owing to the rich grasses which grow on the fens. *Suffolk*, or *skim-milk*, is round and thin, weighing from 25 to 30 pounds each, and is the best keeping cheese made in England. *Wiltshire* resembles the Cheshire; but is poorer, and of inferior flavour. It is apt to become scurfy, to prevent which it is generally coated over with red paint. *Yorkshire*, or *cream cheese*, is the same as the slip-coat cheese, already mentioned.

Foreign Cheeses. — The most remarkable of these are the following: — *Parmesan* is chiefly made at Parma and other places in Lombardy, of the curd of skimmed milk hardened by heat. Its flavour is said to be owing to the rich pastures of that part of Italy, where all plants, from the greater quantity of bright sunshine than in Britain, have doubtless their aromatic properties greatly increased. *Swiss cheese* is of various kinds; but the chief sorts are the Gruyere or Jura cheese, and Schabzieger or green cheese; the last is flavoured with the seeds and leaves of the melilot (*Melilotus officinalis*). *German cheeses* are of different kinds; but none are celebrated, unless we except that of Westphalia, which is made up into round balls or short cylinders, under a pound weight each. The peculiar flavour which this cheese acquires arises from the curd being allowed to become putrid before it is compressed. In Holland very good cheese is made, particularly the Edam and Gouda cheeses; the former is very salt, and keeps well at sea. In many parts of the Continent, and even in the interior of Poland and Russia, there are imitations of English cheese made; but what may be called the indigenous cheese of the Russian empire is nothing more than salted curd put into a bag and powerfully pressed, and taken to market as soon as it is made, in the same manner as butter is. In some places, instead of a press, the whey is forced out of the curd by putting it into a long cloth midway between the two ends, while a person at each end twists the cloth in an opposite direction, and thus wrings out the whey. In some miserable Russian villages the curd is exposed for sale in small lumps, retaining the marks of the fingers, which shows that no other pressure has been employed than what can be given with the hand.

In France the Roquefort cheese is the most esteemed, and next that of Neufchatel. The former somewhat resembles Stilton, but is much inferior; and the latter is a cream cheese, seldom exceeding a quarter of a pound in weight.

CHEESE-MITE. *See* PIOPHILA.

CHEE'TAH, or CHEETA. A Mahratta vernacular name, applied both to the *Felis jubata* and the *Felis leopardus*. It is to the former species, or hunting leopard, that the term is confined in this country.

CHEI'RONE'CTES. (Gr. χειρ, *hand*, and νηχω, *I swim*.) A genus of spine-finned fishes, having the pectoral fins supported, like short feet, upon peduncles. By means of this organization the cheironects can creep over the mud or sand when left dry by the receding tide; they also propel themselves along by short leaps, and in this way seize upon insects which may be hovering about; whence they have obtained the name of frog-fishes. The gill cavity is large, but the outlet very small, and the quantity of water which can thus be retained enables the cheironects to remain out of water longer than fishes in general can do. The term *Cheironectes* is applied by Illiger to a genus of opossum having the hinder hands webbed. Some naturalists adopt this application of the term, and apply to the genus of fishes so called by Cuvier the name *Antennarius*, originally given to the cheironects by Commerson.

CHEIRO'PTERA. (Gr. χειρ, *a hand*, and πτερον, *a wing*.) An order of Mammalia, characterized by having the anterior extremities, and especially the hands, so modified as to serve the office of wings, the fingers being extremely lengthened, and connected together by a thin membrane. Of this order the common bat (*Vespertilio murinus*) may be regarded as the type. The order includes very numerous and diversified species, which have been grouped by De Blainville, who has devoted an especial study to them, into three principal divisions. Of these the *first* includes the largest species, called "flying-foxes:" they are, however, vegetable-feeders, and are characterized by having the ears and nose of a simple form; the two innermost fingers of the hand armed with claws, and of the ordinary structure; the tail, and the web of skin connecting the hind-legs, and called the "interfemoral" web, very short, or wanting; and lastly, by having the molar teeth separated by intervals, and of simple structure. These bats are distributed over the warmer latitudes of the old continent, and extend to the islands of the Pacific ocean. The *second* division has the nose complicated by variously shaped and grotesque membranous foliations; the first or innermost digit alone retains its ordinary structure and armature; the molar teeth are beset with sharp tubercles; and the food of these species consists of insects, or the blood of higher organized and larger animals. The vampire-bats of South America belong to this group, which also includes the horse-shoe bats (*Rhinolophi*), and other genera distributed over all parts of the old world. The *third* division of *Cheiroptera* has the nose constantly simple; the other characters as in the second. It includes the bats properly so called, which are uniformly insectivorous, and of small size.

CHE'LA. (Gr. χηλη, *pincers*.) The first pair of forcipated extremities of the crab, lobster, and other crustaceans.

CHE'LICERES. (Gr. χηλη, *pincers*, and κερας, *a horn*.) The term applied by Latreille to two appendages of the head of the Arachnidans, or spiders and scorpions, which appendages he considers as representing the mesial antennæ of the *Decapod Crustacea*, here converted into manducatory organs.

CHELO'NIANS, *Chelonia*. (Gr. χελωνη, *a tortoise*.) The order of Reptiles, including the tortoises, terrapenes,

and turtles; characterized by the body being inclosed between a double shield or shell, out of which extend the head, tail, and four extremities. The land tortoises have the power of retracting all these parts within the shell.

CHEMISTRY. (The word is probably derived from the Coptic root *chems* or *hhems*, signifying *obscure* or *secret*. The German word *geheim* is apparently of the same origin.)

Chemistry is a department of science, the objects of which are to investigate the nature and properties of the elements of matter, and their mutual actions and combinations; to ascertain the proportions in which they unite, and the modes of separating them when united; and to inquire into the laws and powers which preside over and affect these agencies. As an *art*, chemistry may be traced to a very remote period; but it can scarcely be said to have existed as a *science* previous to the commencement of the seventeenth century: and in tracing its early history we shall find the principal materials upon which it is founded in the works of Bacon, Boyle, Hooke, Mayow, and Newton.

As *induction from experiment* is the exclusive basis of chemical science, little progress could be made in it till the futility of the ancient philosophical systems had been exposed, and their influence annihilated, and till the necessity of that form of severe experimental inquiry had been established which "first procures the light, and then shows the way by its means." Upon such foundations, laid by Bacon, the other philosophers whose names have been mentioned proceeded to bring together and arrange the materials which had been furnished by their predecessors, and were thence led into that train of true philosophical reasoning and research which served as an emulatory example to their immediate successors, and which has led in our times to the gigantic results of modern discovery.

It is well known that the alchemists had accumulated a number of valuable but isolated chemical facts, and that they had explored with considerable diligence the abstract properties and mutual agencies and relations of the greater number of natural products; but, with few exceptions, they neglected their useful and obvious applications, and wasted their labours upon unattainable and chimerical projects. Their discoveries and inventions, as Lord Bacon justly and forcibly observes, "are well represented in the fable of the old man who left an estate to his children, buried, as he said, in his vineyard, which therefore they fell to dig and search for with great diligence; whereby, though they found no gold in substance, yet they received an abundant vintage for their labour. So assuredly has the search and stir to make gold produced a great number of fruitful experiments."

Alchemical speculations, including the attempts at the conversion of mercury into gold, and the search after antidotes and universal remedies, were vigorously carried on during the sixteenth and seventeenth centuries; and many amusing accounts of the professors and adepts of those periods have been handed down to us by the chemical historians of the time. Those who are curious upon these subjects may consult Mangetus, *Bibliotheca Chemica*, and the *Theatrum Chemicum* of Elias Ashmole: the latter contains "several poeticall pieces of our famous English philosophers, who have written the hermetique mysteries in their owne ancient language," but their perusal is labour lost; not so, however, with Basil Valentine, Paracelsus, Van Helmont, and Glauber, in whose writings we not only find the materials so happily worked upon by Hooke and Mayow, but which also abound in announcements of important practical discoveries, and in hints to which many of the improvements of modern times may be plausibly traced.

Basil Valentine of Erfurt was born about the year 1400; his writings, although tinctured with the follies of alchemy, are full of shrewd and intelligent remarks: he was the discoverer, apparently, of nitric and of sulphuric acid, and of many antimonial preparations, which are fully described in his *Triumphal Chariot*. Philip Hochener, more commonly known under the name of Paracelsus, and who died in 1541 at Saltzburgh, in the forty-third year of his age, is chiefly celebrated for the boldness and assiduity with which he introduced chemical preparations into the practice of medicine; he did little, however, as a discoverer. Van Helmont, one of the soundest writers of his period, was the first who seems to have paid attention to the nature of gaseous bodies, and to the distinction between permanent gases and vapours: the word *gas* first occurs in his works; and under the term *gas silvestre*, he seems to allude to what was afterwards termed *fixed air*. None, however, of these early practical chemists come into competition with Glauber. He was an active experimentalist, and an acute reasoner; and in reference to his discoveries we may enumerate among them the distillation of muriatic acid from a mixture of sulphuric acid and common salt; the purification of the residuary sulphate of soda, which he termed *sal mirabile*, and which still bears his name; the production of ammonia by the distillation of bone, and its conversion into *sal ammoniac* by the addition of *spirit of salt;* the preparation of sulphate of ammonia, which he terms *secret sal ammoniac;* the formation of blue vitriol by the action of sulphuric acid upon the green rust of copper; the composition of numerous earthy, alkaline, and metallic salts; and lastly, the evolution of vinegar during the destructive distillation of wood, for which he describes and delineates the distillatory apparatus, under the name of "a press for extracting the juice of wood," and the uses of which, together with those of the oil of tar and other products, he describes at length, closing his discourse with a statement of his apprehension that he shall be by many disbelieved; but "it contented me," he says, "that I have written the truth, and lighted a candle to my neighbours." Glauber also published a pamphlet, entitled "*The Consolation of Navigators; in which is taught how they who travel by sea may preserve themselves from hunger and thirst, and also from those diseases which are wont to happen in long voyages: written for the health, comfort, and solace of all those who travel by water for the good of their country.*" The sensible plan of employing extract of malt as a portable vegetable diet, and diluted muriatic acid to quench thirst, is here recommended; and many of the medicinal uses of that acid are dwelt upon, among which are some that have been claimed as recent discoveries. On the whole, there is no author, contemporary with Glauber, who has written so much to the purpose, and who, as it were, anticipated so many of our modern scientific improvements.

Reverting to the names of Boyle and his eminent associates, we are reminded of the origin of the *Royal Society of London for the Improvement of Natural Knowledge*, which was incorporated by Charles II. in the year 1662, and of which Boyle and Hooke were active and distinguished members. Boyle died in 1691. His station in life, his mild and prepossessing disposition, his strict honour and integrity, and the unaffected earnestness with which he promoted experimental inquiry, tended to shed a lustre on his pursuits, to elevate their character with the world, and to draw into their precincts many who without such an example would have passed their lives in that listless inactivity then too common with those upon whom fortune smiled: among these Mr. Boyle made many converts.

Boyle's Essays on the successfulness and unsuccessfulness of Experiments, and the Preface to his Philosophical Writings, are in the genuine spirit of experimental research; but the new and important aspect assumed about this time by such pursuits is perhaps chiefly due to Dr. Robert Hooke (born in the Isle of Wight in 1635, and died in London in 1702). Among his views and discoveries which bear upon the progress of chemical philosophy, the most important are those relating to the phenomena of combustion, and to the part which the air performs in that process; his notions upon these subjects are remarkable for their boldness as differing from the prevailing theories of the day, and for their correctness as superseding the objections to which those theories were liable. From the hints contained in the writings of the alchemists, it appears that the phenomena of combustion were referred to a subtile and highly volatile principle, which, agitated and expanded by heat, produced *flame* and *fire*. When metals were exposed to the action of heat the greater number of them were observed to alter their appearance, and, losing their brilliancy, became converted into an earth-like powder or *calx*. It was generally admitted that in this process the particles of the combustible were thrown into violent vibrations, and in that way transformed into heat and light. But it had been also remarked that in certain cases of combustion, and especially as regards the metals, the phenomenon was attended by an actual increase of weight in the burning body, and that this result was incompatible with the theory which assumed the conversion of the combustible into heat and light, or the evolution of that principle of inflammability which by Becher and Stahl and the chemists of that school was termed *phlogiston*. About the year 1630 a remarkable tract appeared in France relating to this subject, by Jean Rey, a physician of Perigord. Le Brun had melted two pounds six ounces of lead, and found that in six hours the whole had been converted into calx; but that instead of having lost *phlogiston*, or any other ponderable matter, it had actually increased in weight to the extent of many ounces. Puzzled by this result, he consulted Rey as to its cause, who immediately undertook an experimental inquiry, which led him to refer the increase in weight in this and similar cases to the *fixation of air*. This inference was amply supported by the researches of Boyle and of Hooke: the former found that no combustible would burn under the exhausted receiver of the *air-pump*, and consequently that the presence of air was requisite; and Hooke, finding that however intensely charcoal was heated, it would not *burn* when air was excluded, infers "that air is the universal dissolvent of inflammable bodies, and that this dissolution generates heat, which we call *fire*." But he went a step beyond this, and

attributes the power of supporting combustion to a principle in the atmosphere, "like unto, or the very same as, that which is fixed in saltpetre;" for he had observed the power of that salt as a supporter of combustion. His words are as follow:—"The dissolving parts of the air are but few, and hence the atmosphere is like those spirits which have much phlegm mixed with them, and become soon glutted; whereas saltpetre abounds more in those solvent particles, and hence a little will dissolve a great sulphurous body quickly and violently; and as other solvents, though but weak, quickly consume the dissoluble body if the supply be renovated, so air applied to a shining body by a bellows will dissolve it as rapidly as saltpetre." From all which he concludes that there is no element of fire, but that flame results from the mutual chemical action of the combustible upon a part of the atmosphere. (*Hooke's Micrographia.*) Hooke also alludes to the part performed by *air* in the process of respiration; and in his *Lampas*, published in 1677, has given a beautiful explanation of the burning of a candle. He attributes the light and heat to the action of the air upon the combustible matter of the flame, and shows that the interior of the flame is not luminous, by the simple expedient of viewing its section through a thin piece of glass or of mica.

These doctrines of Hooke were further illustrated by John Mayow (born in Cornwall 1645, died in London 1679), who not only experimentally corroborated them, but pointed out the connection between combustion and respiration, and showed that that part of the air concerned in the support of flame was also essential to the life of animals. He placed a candle under a bell-glass, and when it would no longer burn, he found that on rekindling it it was immediately extinguished by the same air; he then placed a mouse in a confined portion of air, and it soon manifested the want of its renewal; he then put the mouse under the same bell-glass with the candle, and found that it only lived half the time that it had survived without the candle; he then reversed the experiment, and endeavoured to burn a candle in air which had been breathed, and finding that it went out, he concluded that the "nitro-aerial particles" of the air were as essential to respiration as to combustion, and that they were in both cases *absorbed;* and he even refers *animal heat* to the influence of the air upon the blood.

But Mayow's claim to a distinguished place in the history of chemistry is not merely founded upon the sagacity with which he followed up these views; he was the first who distinctly expounded the nature of *chemical affinity*, and who taught its independence of those mechanical forms of the particles of matter to which it had been referred, and showed, contrary to the prevailing tenets, that in cases of combination the particles of the acting bodies were not annihilated, but that they still existed in the compound, and might again be elicited from it with all their former powers and properties. These notions he illustrates by a series of extremely apposite experiments; and proceeds to explain *decomposition* upon the principle of inequality in the respective attractive forces of the acting bodies, a doctrine which was afterwards verified and further explained by Newton, whose masterly sketch of a theory of chemical attraction, given in the queries to the third book of Optics, is nearly in the language and entirely in the spirit of his predecessor. The theory of combustion and of affinity, thus established upon the basis of experiment by Hooke and Mayow, constitute the foundation upon which most of the superstructure of modern chemistry rests; the former was extended and embellished by Lavoisier, and the latter has gradually risen into the atomic and equivalent doctrine. There are three principal points connected with the vast extension and importance of chemical science as we now find it, to which it becomes necessary therefore to allude; namely, the investigations relating to the philosophy of *heat*, those connected with *pneumatic chemistry*, and those establishing the connection of *electrical* with *chemical* phenomena.

It was not till towards the middle of the seventeenth century that such perfection was given to the construction of the *thermometer* as to enable it to be used as an accurate and comparative measure of temperature. Dr. Halley seems to have been the first who applied the uniform temperature of boiling water to obtain one fixed point for its graduation; the constant temperature of water in the act of freezing seems also to have been noticed about the same time by the Florentine academicians, and by Newton; and these two points being thus determined and ascertained, together with the causes of their occasional discrepancies, the graduation of the thermometer became easy, especially when the advantages of mercury had been pointed out by Halley, together with the mode of sealing it in the thermometer tube. (*See* THERMOMETER.) But the great and important step in the philosophy of heat was the consequence of Dr. Black's discovery of the state in which heat exists in liquids and vapours, and upon which he founded his beautiful theory of *latent heat*. This theory gave a satisfactory solution of a multitude of natural and artificial phenomena previously unexplained or unobserved, and laid the foundation of those wonderful improvements in the theoretical and practical construction of the steam engine which were soon afterwards carried into effect by Watt.

Dr. Black was born in 1728 on the banks of the Garonne, and educated at Belfast, and afterwards at Glasgow: in 1766 he was appointed to the chemical chair in the university of Edinburgh, where he died in 1799. He not only made the grand discovery of the latency of heat, but he enriched chemistry with other discoveries; among which that of the presence of carbonic acid in the mild earths and alkalies, and the cause of their causticity, was especially perfect and important. These facts, including also the discovery of carbonic acid, or, as it was then called, *fixed air*, were first published in 1756; his ideas respecting the combinations of heat with ponderable matter were perfected in 1764.

Another and distinct series of inquiries, having important bearings upon the philosophy of heat, had its origin with the Florentine academicians towards the end of the seventeenth century, and was afterwards sagaciously followed up by Scheele, Leslie, and others; it relates to the *phenomena of radiation*, to the manner in which heat is propagated through space, and to those of its emanation from luminous and incandescent bodies, and to its connection with light.

Pneumatic Chemistry had its origin in the experiments of Hooke and Mayow, and was subsequently extended by Hales, and more especially by Priestley. Mayow obtained hydrogen gas by the action of iron on dilute sulphuric acid, and observed the formation of nitrous gas during the action of aquafortis upon the same metal; but it was not till the commencement of the last century that the distinctive characters of the gases and their importance as chemical agents began to be duly appreciated. Connected also with this subject is the rise and progress of the chemical physiology of vegetation. Dr. Stephen Hales was born in Kent in 1677, and died at Teddington in 1761. He began the communication of his researches to the Royal Society in 1717, and in 1727 published his "*Statical Essays, containing an essay towards a natural history of vegetation, of use to those who are curious in the culture and improvement of gardening; also a specimen of an attempt to analyse the air by a great variety of chemico-statical experiments, which were read at several meetings before the Royal Society.*" In 1733 a second volume of these Essays was published, containing "*Hæmastatics, and experiments on the stone of the kidney and bladder.*" In his various experimental researches detailed in these essays, Dr. Hales describes many curious facts, and shows much ingenuity in the contrivance of apparatus; but he furnishes a striking instance of the facility with which the mind is led away from the true path of discovery by preconceived opinions; for having predetermined that the various gaseous products which he obtained were mere modifications and contaminations of common air, he missed much that was fairly within his grasp. He observed, for instance, that air was absorbed during the combustion of phosphorus in close vessels, but he examined none of the products; he collected the air evolved during the destructive distillation of wood, and found it fatal to animals; from Newcastle coal he obtained one third of its weight of gas; and from nitre, 180 times its bulk; but he did not leisurely examine any of these products. He found that iron filings and oil of vitriol would not evolve gas unless water was present; but instead of stopping to examine the properties of the hydrogen gas which he thus obtained, he hastens on to irrelevant observations, being more eager to multiply experiments than to examine their results. In the same way he details with minute accuracy the quantity of air generated during the distillation of blood, tallow, sal ammoniac, and many other substances, without drawing a single useful inference. In his experiments on respiration too, he obtained results of extreme interest, and is often upon the verge of most important discoveries; but instead of being incited by the novelty of his results, and the extent of the field of investigation opened by his researches, he drops them upon the occurrence of the slightest difficulty. His examination, however, of the motion of the sap in vegetables was pursued upon a more regular and satisfactory plan; he ascertained the quantity of matter imbibed and perspired by several plants and trees; the proportion daily lost by the leaves, and their influence upon the absorptive powers of the root; and the relation of various states of the atmosphere as to temperature and moisture upon these functions. He endeavoured to confer different flavours upon fruits by impregnating the soil with perfumed waters, and he found that the odorous particles were rejected by the living vessels, but that they affected the dead parts of the tree; he compares the functions of the leaves of evergreens with those of deciduous shrubs and trees; he notices the effect of cutting a ring of bark off the branch of a tree in promoting the growth of its leaves and fruit; and, lastly, shows that air is some-

times absorbed or inspired by plants, and gives some interesting views relative to the germination of seeds.

When it is recollected that Hales wrote at the commencement of the last century, that few models of good scientific composition were then extant, and that a pompous and obscure style was prevalent among most of his contemporaries, we must admire the perspicuous and unadorned manner in which he details his facts and observations. He has in this respect all the merit which belongs to Boyle without his diffusiveness; and a pleasing vein of sound and unaffected morality accompanies his arguments, and leads him, whilst endeavouring to unveil the mysteries of nature, to direct our attention with becoming modesty to the extreme penury of man's wisdom, when compared with the admirable adjustments of causes and effects discoverable in the lowliest works of the Creator.

But although Mayow, Hooke, and Hales had done much towards establishing the interest and importance of gaseous chemistry, it is to Dr. Joseph Priestley (born at Fieldhead, near Leeds, 1733; died in Pennsylvania, 1804) that we owe the principal progress in this branch of our science. He directed his attention to it with a degree of activity and skill then peculiarly his own, and in the number of his discoveries left his contemporaries far behind, while he certainly rivalled them in their interest and importance, which is the more surprising when we reflect that he generally seems to have considered his philosophical studies as subordinate to his more severe and serious occupations. He first turned his attention to chemistry about the year 1768. He used to amuse himself with experiments on fixed air and on artificial mineral waters; and one experiment, as he says, leading to another, he soon collected those materials which he laid before the Royal Society in 1772, under the title of *Observations on different Kinds of Air*. It was on the 1st of August, 1774, that he made the great discovery upon which so much of the subsequent progress of chemical science has depended, namely, that of *oxygen gas*. He obtained it by exposing a quantity of *red precipitate of mercury* to the action of the sun's rays concentrated upon it by a lens; the red precipitate was contained in a flask filled up with mercury, and inverted in a basin containing the same metal. "I presently found," he says, "that by means of this lens air was expelled from it very readily. Having got several times as much as the bulk of my materials, I admitted water to it, and found that it was not imbibed by it; but what surprised me more than I can well express was, that a candle burned in this air with a remarkably vigorous flame, very much like that enlarged flame with which a candle burns in nitrous air exposed to iron or liver of sulphur; but, as I got nothing like this remarkable appearance from any kind of air besides this particular modification of nitrous air, and I knew no nitrous acid was used in the preparation of the *mercurius calcinatus*, I was utterly at a loss how to account for it." He then goes on to show that *red lead* and *nitre* also afford oxygen at a red heat, and calls it, consistently with the theory of combustion which was then prevalent, *dephlogisticated air*, regarding it as common air deprived of phlogiston, and consequently possessed of a powerful affinity for that imaginary principle.

Shortly after the discovery of oxygen, Priestley ascertained that plants had the power of purifying air which had been vitiated by the respiration of animals, and that oxygen was evolved by aquatic plants in water containing carbonic acid. Nitrous and nitric oxide, muriatic acid, and ammonia were also amongst his gaseous discoveries. In 1772 Dr. Rutherford had demonstrated that a large portion of the atmosphere consisted of a peculiar gas differing from fixed air, yet, like it, extinguishing flame and unfit for respiration; to this component part of the atmosphere Dr. Priestley gave the name of *phlogisticated air*, and pointed out the means of ascertaining its relative proportion to the oxygen of the air by the agency of nitrous gas.

Another celebrated name connected with the progress of this department of chemical science is that of Cavendish. In 1776 he presented the Royal Society with a dissertation on inflammable, fixed, and nitrous air. The two latter gases had been well described by his contemporaries; but nothing very precise was known respecting inflammable air, till its sources and properties were described in Cavendish's masterly paper. He found that it was the lightest known substance, and in conjunction with Watt he showed that by combustion with oxygen *water* was the only result; hence the term *hydrogen* subsequently applied to this gas. Cavendish also discovered the composition of nitric acid; and by passing a succession of electric sparks through common air, and through artificial mixtures of oxygen and nitrogen, he succeeded in effecting their combination, and in producing that acid.

Two capital and extremely important steps were thus made in chemical science, chiefly by the joint labours of Priestley and of Cavendish; namely, the composition of the atmosphere and of water; and about the same time Scheele (born at Stralsund in 1742, and died at Köping near Stockholm in 1786), in his dissertation on Manganese, made known the existence of chlorine, or, as he then termed it, of dephlogisticated muriatic acid gas. His "Observations and Experiments on Air and Fire," and on "Heat and Light," are also masterly productions, and contributed, in conjunction with the labours of his eminent contemporaries, to invest chemistry with a degree of interest and importance which gave it an entirely new and distinct aspect, and an elevated rank in physical science.

It was at this period that Lavoisier and his associates in Paris undertook that celebrated reform of chemical nomenclature which ended in the banishment of phlogiston, and introduced a logical precision before unknown into the precincts of chemistry. Lavoisier experimented upon a magnificent scale, and with a degree of statical accuracy which stamped his researches with a new and valuable character. By a series of beautiful experiments he determined the relative proportions of the elements of the atmosphere and of those of water; he rejected all supporters of combustion except oxygen, and regarded it as the sole source of the heat and light evolved during that process; he endeavoured to prove that gases were constituted by the union of ponderable bases with *caloric*, or the *matter of heat*, and examined, upon a splendid scale and with princely apparatus, the results of the combustion of sulphur, phosphorus, carbon, and the metals; he inferred that oxygen was the universal *acidifying* principle; and by a series of well conceived researches he demonstrated the identity of charcoal and the diamond, and showed that when burned in oxygen they yielded carbonic acid gas. Lavoisier was also the first who examined with requisite accuracy the products of the distillation of animal and vegetable substances; he also inquired with more success than any of his predecessors into the phenomena of fermentation, and, by examining the contents of certain vegetable juices, previous to and after that process, he drew some curious and important conclusions respecting the changes that take place: he also extended and corroborated Scheele's views as to the importance of the chemical agencies of light.

These, and a variety of other details, are embodied in Lavoisier's *Elemens de Chimie*, which appeared at Paris in 1789; a work which eminently displays the extent and perspicuity of his views as a theoretical and experimental philosopher, and which contains a masterly refutation of the phlogistic doctrines. The abstract facts, however, upon which this refutation rests may be traced to Mayow, Hooke, Priestley, and Scheele. It has been stated that the prominent features of the French theory were its explanation of the phenomena of combustion and of acidification, the presence of oxygen being deemed essential in both cases. That air is the food of fire was known at a very remote period; that it causes the increase of weight sustained by metals during their calcination was shown by Rey early in the seventeenth century; that a part only of the atmosphere, identical with a matter contained in saltpetre, is concerned in the support of flame, was explained by Hooke in 1667; and that the vital, or igneous spirit, as he terms it, contributes to the formation of acids was asserted by Mayow in 1674. Here, therefore, without even infringing upon the eighteenth century, we have, in explicit detail, the principal facts and arguments requisite for the construction of the French theory; and if to these we add the discovery of oxygen by Priestley, and of the composition of water and of nitric acid by Watt and Cavendish, what then becomes of its title to originality?

The influence of the researches connected with the philosophy of heat, and of those relating to the production, properties, and constitution of the gases, upon the improvement and extension of chemistry, will now be apparent; but one of the most fertile sources of its recent progress is of a distinct and remarkable origin, namely, the discovery of *the chemical influences of electricity*.

In 1790 Galvani of Bologna ascertained that certain spasmodic or convulsive contractions might be produced by the action of electricity upon the nerves of a recently killed animal; and that if the sciatic nerve of a frog be laid bare and touched with a piece of zinc, whilst at the same time the muscle is touched with gold, similar effects to those of electricity are produced whenever the metals were brought into contact, or connected together by conductors of electricity; if nonconductors were used, no spasm ensued. He accounted for these and similar effects by assuming that the nerves and muscles were in opposite electrical states, and that the spasms were the consequence of their annihilation or discharge.

Volta, on the other hand, finding that two different metals were essential, referred the phenomena to the electromotive power of the metals; and following up this idea, he soon succeeded in producing that extraordinary form of electro-generative apparatus which is now known under the name of the Voltaic pile or battery, consisting of al-

ternations of two metals with an intervening fluid: zinc, copper, and diluted acids are the substances now generally resorted to. It has lately been shown by Faraday that *chemical action* is the exclusive source of the electricity of these Voltaic arrangements; but their history and the theory of their phenomena will be given elsewhere.

In the year 1800 the *chemical powers* of the Voltaic pile were first observed in regard to the decomposition of water and certain saline solutions, by Messrs. Nicholson and Carlisle; these were more accurately investigated in 1803 by Hisinger and Berzelius; and in 1806 Sir H. Davy communicated his celebrated lecture "On some Chemical Agencies of Electricity" to the Royal Society. He had previously (1801) given a paper to the Society containing an account of some galvanic combinations formed by the arrangement of single metallic plates and fluids, analogous to the galvanic apparatus of Volta; but it was not till the publication of the Bakerian Lecture above alluded to that the importance of *electro-chemical science* could be appreciated. It contains a masterly outline of the subject; and its details present a fine specimen of experimental inquiry, especially in reference to the manner in which he traces out the decomposing powers of an electrical current in effecting the separation of the elements of water, the skill with which the conflicting results of other experimentalists are examined and explained, the caution with which he proceeds from experiment to theory, and the sagacity with which he employs theoretical views as the source of new experimental inquiries. Following the path which he had thus opened for himself, it led him on to the most important and extraordinary results, among which were the decomposition of the alkalis and earths, and the discovery of an entirely new class of metals.

But the eradication of established errors is perhaps a more difficult task than the promulgation of new theories; and in this Davy rendered a memorable service to chemistry by his several papers on "Oxymuriatic Acid," in which he successfully establishes the views of Scheele regarding its nature, and refutes and subverts those of the French school, and which had been sanctioned by the chemists of Europe: he demonstrates the existence of acids without oxygen, and lays the foundation of the theory of the *hydracids*.

To these masterly researches Davy added a third series, of equal if not superior importance; those relating to the *safety lamp*. His first paper upon this subject is printed in the *Philosophical Transactions* for 1815, and was followed by four others. Finding that flame would not recede through tubes of very small diameter, the idea occurred to him of constructing a lamp which should have no connection with the surrounding air except by capillary tubes; and he inferred from previous experiments that such a lamp might safely be employed in coal mines infested by fire-damp. He then endeavoured to ascertain the extent to which the tubes might be *shortened* without interfering with this principle of safety, and was thus led to cut them down, till their transverse section resembled a series of meshes. This approached so closely to *wire-gauze* that he was induced to try how far that tissue would prevent the passage of flame; and finding it effectual, he employed it in the construction of his lamp, and ultimately adopted the simple and efficient arrangement now in general and successful use. During the experimental investigations upon which the discovery of the safety lamp was founded, Davy ascertained a number of curious facts respecting the constitution and temperature of flame, which, with other parts of his general inquiry, are not less ingenious than original. In November, 1820, Sir H. Davy became president of the Royal Society, and continued to contribute papers as heretofore, some of them upon subjects of much interest, ably and philosophically discussed: among them the essays on the modes of protecting the copper sheathing of ships deserve especial notice; they have furnished hints for the preservation of iron and other corrodible metals from the influence of air and water, and promise to lead to results of great practical importance. In the course of the year 1827 his health became seriously impaired; he passed the greater part of the year 1828 in Italy, and terminated his memorable existence at Geneva in May, 1829, in the fifty-second year of his age.

We have now briefly sketched the principal circumstances in the history of chemistry bearing upon its origin and progress as a science, without, however, adverting to the labours of contemporaries; it remains to add a short notice respecting the art of *Analysis*, and the important consequences of which the prosecution of that branch of the science has been productive.

Analysis was first scientifically pursued by Bergman of Sweden. He was born in 1735, and died in 1781, in consequence, as is said, of too intense application to his studies. The use of *tests* for the discovery of certain substances held in aqueous and other solutions, is first particularly dwelt upon by Boyle. He used vegetable colours for the detection of acids and alkalis, and noticed the cloudiness produced by nitrate of silver in solution of common salt. In 1667 Du Clos undertook an examination of the mineral waters of France, and in 1686 Hierne published some clever experiments upon the same subject in Sweden. In 1726 Boulduc used spirit of wine to precipitate the salts insoluble in that menstruum; in 1755 Venel pointed out the existence of fixed air in the waters of Selters, Spa, and Pyrmont; Lane, in 1769, showed the method of imitating chalybeate springs; and in 1772 Priestley published directions for saturating water with fixed air. The above and other tests were particularly examined, their accuracy compared, and the best modes of applying them pointed out by Bergman: his dissertations on the waters of Upsal, on sea-water, and on the artificial preparation of medicated waters, each exhibit proofs of his skill as an analyst, and accuracy as an experimenter. He also turned his attention to the analysis of minerals; his essay, entitled *De Minerarum Docimasiâ Humidâ*, must be considered as the parent source of that branch of analytic chemistry so successfully followed up, though upon a limited scale, by Scheele, and in the improvement and extension of which Klaproth passed his long and laborious life. Klaproth was born at Wernigerode in Prussia in 1743, and died at Berlin in 1817. He published 207 essays in his "Contributions towards the Chemical Knowledge of Mineral Substances." Another eminent name among chemical analysts is that of Vauquelin, who died at an advanced age in Paris in 1829. He was originally a peasant boy in Normandy, and afterwards was employed in Fourcroy's laboratory, where he not only acquired great dexterity in the ordinary duties of his situation, but became an expert and original analyst. He afterwards rose to high eminence in his profession; and his numerous and important contributions and discoveries are lasting monuments of his skill and industry.

Among the improvers of analytical chemistry in this country Chenevix, Howard, and Tennant deserve particular mention; but to none is this part of the science more deeply indebted than to Dr. Wollaston. With him and Davy all that is practically useful in the theory of definite proportionals, or, as it is often called, the *Atomic Theory*, may be said to have originated; though the facts upon which it is founded were chiefly furnished by the German analysts, and by Higgins of Dublin.

We have in another place given some account of this important subject, and have endeavoured to explain the facts upon which it is founded, and the results to which it leads: its promulgation with us is mainly attributable to Wollaston's suggestions contained in his paper "On a Synoptic Scale of Chemical Equivalents," brought before the Royal Society in November, 1813. Many years previously he had established the important doctrine of multiple proportions in a paper "On Superacid and Subacid Salts." He now showed the practical applications of which the theory was susceptible; and, by connecting the scale of equivalents with Gunter's sliding rule, has put into the hands of the chemist an instrument infinite in its uses, and equally essential to the student, the adept, and the manufacturer.

There remains to be noticed a distinct branch of chemistry of extreme interest and importance, but beset with peculiar difficulties; namely, that relating to *organic substances*. Some progress was made in it by Scheele; but it has chiefly been enriched by the labours of modern and contemporary philosophers, and in their hands has assumed an entirely new aspect. The composition of organic bodies may be viewed in two ways; either as relates to their ultimate elements, or to their proximate groups. The former are remarkably few in number, and are almost exclusively confined to four; namely, carbon, hydrogen, oxygen, and nitrogen. These, by their varied and extraordinary union, give rise to innumerable secondary products or proximate principles. That the same elementary forms of matter should give rise to such infinitely varied products, merely in consequence of the varying proportions in which they are combined and the circumstances under which they have been presented to each other; that food and poisons, alkalis and acids, sweets and bitters, and, in short, the most opposite and dissimilar qualities, should arise out of such causes—is extremely remarkable; and although every day is adding to our information, and clearing difficulties from this department of chemistry, it is but in its infant state.

In looking at the present state of chemistry, it must be allowed that it exhibits a most promising aspect; the study of its abstract principles is calculated to keep the curiosity constantly on the alert, and awaken an intense and peculiar interest; and it is quite impossible to glance at its recent progress, and at the extraordinary discoveries which are daily rewarding the labours of its skilful cultivators, without anticipating most important consequences. Should its progress during the ensuing century only equal that of the past, it must lead to results deeply affecting the interests and welfare of mankind; but as it has hitherto acquired strength with its progress, its wonders may be expected to accumulate in a much higher ratio. We already seem to be on the brink of some great discovery connected with those powers and

properties of matter which we call *electrical*. Their association with, and convertibility as it were into, heat, light, and magnetism, and their identity with the cause of chemical affinity, have already been turned to great account; and it is only necessary to assume the possession of a more unlimited command that we at present enjoy over the production or evolution of this extraordinary agent, less dependent and scanty means of summoning it into existence or activity, and a more intimate acquaintance with its forms and qualities, to confer the highest interest upon our speculations. Its chemical powers would then be perpetually called into action as a substitute for the more sluggish or circuitous and difficult methods of ordinary decomposition. Its single application to the evolution of oxygen and hydrogen from water would alone work wonders; whilst the facility of its conveyance and transmission, its ubiquity, and its varied attributes in those different states which for want of more explicit knowledge of their cause have been termed *quantity* and *tension*, seem to point it out as of unlimited application to human uses. Through its instrumentality telegraphic communication has not only been accelerated, but rendered independent of weather, and equally facile by night as by day; and even in the present state of this invention there seems no reason against such conveyance of our thoughts, wants, and wishes, so as to transmit them over the globe with a rapidity as much beyond all previous experience, as the travelling on a rail-road exceeds that of a common carriage.

Connected, therefore, with the progress of the higher departments of chemical science, and indeed intimately interwoven with it, is the advancement of its application to all the arts of life. It is often supposed that the successful applications of chemistry to the arts have been rather the results of accident or chance than the consequence of those apparently abstract studies, and curious rather than useful discoveries, as they are called, in which the truly philosophical chemist is engaged, and in which his labours terminate; but experience justifies no such conclusion. There can be no doubt that Black's researches into those effects of heat which are connected with changes in the state and form of bodies, and especially with the constitution of vapour, led Watt into that train of reasoning by which his improvements in the steam engine were ultimately effected. Most of the wonders of modern chemistry must be referred to Galvani's experiments on a dead frog. They led Volta to the construction of the electric pile; and, in the hands of Davy and his successors, what important conquests have been attained, and what extraordinary consequences are daily flowing from a source so apparently unpromising and irrelevant! Independent of the new agents which have been placed in the hands of the experimentalist, and of the new and important theoretical considerations which arise out of them, the whole aspect and character of a great department of physical science has been wonderfully changed, extended, and improved; the cause of magnetism has been developed; and a power no less extraordinary and applicable to human uses than light and heat, perhaps indeed the parent of both, is gradually showing us its mysterious relations. Of two great practical consequences have these inquiries already been productive; namely, the electrical telegraph, and the preservation of metals from corrosion. That others are upon the eve of their development cannot be doubted; and in proportion as our knowledge of this agent and consequent power over it is extended, those ends must certainly be attained which we have above ventured to anticipate.

From other departments of this science we are constantly acquiring similar benefits: the progress of gas illumination, the great improvements in metallurgic operations, in the arts of dyeing and calico-printing, in the manufacture of cements, in the preservation of timber from dry-rot, in gilding and silvering the metals, are only a few of the cases in point; even the difficult and apparently isolated researches into the relative proportions of the ultimate elements of the proximate organic products, and the application of the atomic theory to those researches, have not been fruitless, considered in reference to what are termed their practical results and popular and useful applications. The brewer and the distiller are reaping the benefits of such inquiries; the conversion of starch, and even of wood, into sugar, are the practical consequences of theoretical inferences; from the destructive distillation of ligneous matter we are already furnished with our chief supply of vinegar, and with a liquid which, as a combustible and a solvent, has to a great extent superseded the use of alcohol, and may possibly take its place at no very remote period as an intoxicating stimulant: the saw-dust of certain woods has been shown susceptible of conversion into nutriment; and the analysis of bone points it out, when properly prepared, as almost equal to its weight of flesh as an article of human food. In short, of the arts of life the greater number are dependent upon chemical principles; many of them, and perhaps the most important, are exclusively so; others, though apparently mechanical, involve chemical principles: hence the great and growing importance of chemical science as a branch of general education bearing upon political economy, and upon the prosperity of the arts and manufactures.

Having given this outline of the rise, progress, uses, and applications of chemical science, we must refer to other articles for more explicit information upon the different heads that have been alluded to. In reference to further details respecting the history of this department of knowledge, especially as relates to alchemy and to the history of chemical inventions, we may refer to Dr. Thomson's *History of Chemistry*, and to the prefatory chapter of Mr. Brande's *Manual*.

The extent necessarily occupied by chemistry in a map of human knowledge will be evident from the brief definition of the science given at the outset of this article; for it not only leads us to inquire into the composition of every product of nature and of art, but to examine the elements of all the forms of matter, and the laws which govern their mutual actions and reactions. The questions which a chemist propounds to himself, in examining any newly discovered substance, involve therefore a long train of inquiries, which can only be answered and worked out by multiplied *experiments*; for it is impossible to move onwards in this science except upon the basis of experimental research. Accordingly, when a body of unknown nature is presented to us, we endeavour, first to ascertain whether it be a *simple* or a *compound* substance. If simple, to what class of elementary bodies does it belong; is it combustible or incombustible; is it electro-negative or electro-positive; how is it affected by heat; what are its relations to other forms of matter; what its powers of combination; what are the proportions in which it unites with other substances; what are its characters and those of its combinations as a chemical and physiological agent; what are its uses in the arts and in medicine? If it be a compound substance, we inquire into the nature and number of its component parts: are they new, or are they known elements; in what proportions are they combined? We also, as before, examine its thermal and electrical relations, and its useful applications. These, and many other questions which arise in the course of chemical investigation, involve as it were several distinct branches of inquiry, and lead us to contemplate chemistry under two points of view; namely, as an independent science, which embraces the whole field of chemical knowledge, and investigates the chemical relations of bodies without reference to any extraneous considerations—this is *pure, theoretical*, or *philosophical chemistry*; and secondly, as a science having certain objects in common with others, as with mineralogy, medicine, physiology, and the arts — this being *applied chemistry*.

In a subject then so extensive and complicated as chemistry, *systematic arrangement* is of the utmost importance to the teacher and student. In the broad principles of arrangement most writers agree; but in minor details each generally pursues a path of his own. It would be useless, even if it were possible, to enumerate the details of these arrangements as adopted by the leading didactic writers on chemistry; but the basis upon which they are founded deserves a few words of explanation.

The objects of chemistry are all included under one or other of the following heads; namely, —

1. The general powers and properties of matter.
2. The chemistry of elementary substances.
3. The chemistry of compounds.

And each of these require several subdivisions. Thus, under the first head, we include *attraction* and *affinity, heat, light*, and *electricity*; under the second head are included the chemical history and properties of the ponderable *elementary substances*, and their mutual *reactions*, which of course leads on to the third head; namely, to the chemical history and properties of *compound bodies*. To render the systematic arrangements of the elements and their compounds intelligible, it will be necessary to enumerate the former, and point out such of their characters as are connected with their classification.

Every substance upon our globe contains one or more of the following *fifty-four* elementary or simple bodies: some of them are of extremely rare occurrence, others abundant and always with and about us. It will be observed that by far the greater number of them come under the denomination of *metals*; of the others, oxygen, hydrogen, carbon, and nitrogen, are by far of most frequent occurrence, as will be obvious when it is recollected that air and water and all vegetable and animal products include two or more of the last-mentioned substances.

The equivalent or combining proportions of these elements, although mentioned under individual substances in this work, are here subjoined (*see* the articles AFFINITY, ATOMIC THEORY, and EQUIVALENTS), and also the *symbols* by which they are represented.

Table of the Simple Substances, with their Symbols and Equivalent or Combining Weights.

	Equivalents, Hydrogen = 1.	Symbol. (Brande.)	Symbol. (Berzelius.)	Equivalents, Oxygen = 1.
1 Aluminum -	10	*al.*	Al.	1·25
2 Antimony -	65	*ant.*	Sb.	8·125
3 Arsenic - -	38	*ar.*	As.	4·75
4 Barium - -	69	*ba.*	Ba·	8·625
5 Bismuth - -	72	*bi.*	Bi.	9·
6 Boron - -	20	*bo.*	B.	2·5
7 Bromine - -	78	*b.*	Br.	9·75
8 Cadmium -	56	*cad.*	Cd.	7·
9 Calcium - -	20	*cal.*	Ca.	2·5
10 Carbon - -	6	*car.*	C.	0·75
11 Cerium - -	48	*ce.*	Ce.	6·
12 Chlorine -	36	*c.*	Cl.	4·5
13 Chromium -	28	*chr.*	Cr.	3·5
14 Cobalt - -	30	*cob.*	Co.	3·75
15 Columbium -	185	*col.*	Ta.	23·125
16 Copper - -	32	*cu.*	Cu.	4·
17 Fluorine - -	18	*f.*	F.	2·28
18 Glucium -	18	*gl.*	G.	2·25
19 Gold - -	200	*au.*	Au.	25·
20 Hydrogen -	1	*h.*	H.	0·125
21 Iodine - -	125	*i.*	I.	15·625
22 Iridium -	96	*ir.*	Ir.	12·
23 Iron - -	28	*fe.*	Fe.	3·5
24 Lead - -	104	*pl.*	Pb.	13·
25 Lithium	10	*li.*	L.	1·25
26 Magnesium	12	*mag.*	Mg.	1·5
27 Manganese	28	*man.*	Mn.	3·5
28 Mercury -	200	*hg.*	Hg.	25·
29 Molybdenum -	48	*mol.*	Mo.	6·
30 Nickel - -	28	*nic.*	Ni.	3·5
31 Nitrogen	14	*n.*	N.	1·75
32 Osmium	100	*os.*	Os.	12·5
33 Oxygen	8	o.	O.	1·
34 Palladium	54	*pal.*	Pd.	6·75
35 Phosphorus	16	*p.*	P.	2·
36 Platinum	96	*pla.*	Pl.	12·
37 Potassium -	40	*po.*	K.	5·
38 Rhodium	45	*rh.*	R.	5·625
39 Selenium	40	*se.*	Se.	5·
40 Silicium -	8	*si.*	Si.	1·
41 Silver -	110	*ag.*	Aq.	13·75
42 Sodium -	24	*so.*	Na.	3·
43 Strontium -	44	*str.*	Sr.	5·5
44 Sulphur -	16	*s.*	S.	2·
45 Tellurium -	32	*tel.*	Te.	4·
46 Thorium -	60	*th.*	Th.	7·5
47 Tin -	58	*sta.*	Sn.	7·25
48 Titanium -	24	*ti.*	Ti.	3·
49 Tungsten -	100	*tu.*	W.	12·5
50 Vanadium -	68	*va.*	V.	8·5
51 Uranium -	217	*ur.*	U.	27·12
52 Yttrium -	32	*yt.*	Y.	4·
53 Zinc -	32	*zn.*	Zn.	4·
54 Zirconium -	30	*zir.*	Zr.	3·75

The examination of the physical and chemical properties of the preceding elements of matter leads us to classify them according to their analogies. The greater number of them possess the characters of *metals*. Several resemble the metals in certain respects, but are in others widely different; these therefore have been termed *metalloids*. A few are distinguished by entering into peculiar and distinct saline combinations, of which common salt may be taken as the type; these therefore have been termed *halogens*. And lastly, three of the elements are only known in the gaseous form; they have neither been liquified nor solidified, but whenever they are isolated they present themselves as permanent gases; hence they have been designated *gazolytes*. This is the classification of the elementary bodies suggested by Berzelius, and it represents them as follows: —

I.	II.	III.	IV.
Gazolytes.	*Halogens.*	*Metalloids.*	*Metals.*
Oxygen.	Chlorine.	Sulphur.	
Hydrogen.	Iodine.	Phosphorus.	
Nitrogen.	Bromine.	Carbon.	
	Fluorine.	Boron.	

The metals, by far the most numerous of the elementary bodies, are themselves the subjects of various classifications, among which the following is perhaps the most convenient; they are arranged nearly in the order of their respective attractions for oxygen: —

I.	II.	III.
Potassium.	Manganese.	Copper.
Sodium.	Iron.	Lead.
Lithium.	Zinc.	Antimony.
Calcium.	Tin.	Bismuth.
Barium.	Cadmium.	Uranium.
Strontium.	Cobalt.	Titanium.
Magnesium.	Nickel.	Cerium.
		Tellurium.

IV.	V.	VI.
Arsenic.	Mercury.	Glucium.
Molybdenum.	Silver.	Zirconium.
Chromium.	Gold.	Yttrium.
Vanadium.	Platinum.	Thorium.
Tungsten.	Palladium.	Aluminum.
Columbium.	Rhodium.	Silicium.
	Osmium.	
	Iridium.	

The substances in the last division have been but imperfectly examined, and silicium should perhaps rather be regarded as a metalloid than a metal.

In one or other, then, of these classes each elementary body will find a place, but the arrangement only relates to the simple substances; the classification of their *combinations*, which are almost indefinite, is a much more intricate and difficult subject, and it would be impossible here to give even an outline of the different plans which have been pursued or suggested. As far, however, as the teacher of chemistry is concerned, none of the systematic arrangements of compounds can be conveniently adopted; his best plan, therefore, is to develope their history and properties as he proceeds. Having, for instance, discussed the abstract properties of *oxygen* and *hydrogen*, he proceeds to the *compound* which they form, and which is *water*; then he proceeds to the third element, *nitrogen*, and its *combinations* with those previously described; thus, nitrogen and oxygen form five distinct compounds, namely, *protoxide* and *binoxide* of nitrogen, and *hyponitrous*, *nitrous*, and *nitric* acids. Nitrogen also combines with hydrogen to form *ammonia*, and ammonia combines with nitric acid to form the salt called *nitrate of ammonia*. In a state of *mixture*, nitrogen and oxygen constitute the great bulk of the *atmosphere*.

From this brief notice of the mode of dealing with the three elementary bodies of the first class, the reader will readily understand the method of applying the same principle to the entire list; the student will thus be conducted, step by step, from the simplest to the most complicated chemical combinations. It is always convenient, however, in adopting this plan, to exclude the products of organization, and to consider them apart, under a separate head, entitled *organic chemistry*, which is of course subdivided into the *chemistry of vegetable* and of *animal products*.

If, having studied chemistry upon this plan, we look back upon the path which has been traversed, we shall immediately see that the *compounds* may be grouped into classes, related to each other by certain analogies both of properties and composition. Thus we have the class of *oxides*, or combinations of oxygen which are not acid; of *chlorides*, *iodides*, &c., and of *acids*; and these again subdivided into *oxyacids*, and *hydracids*; and lastly, the numerous class of *salts*, or compounds of the acids with salifiable bases.

When compound bodies are susceptible of electro-chemical decomposition (or *electrolytes*) the elements always tend to one or other pole; in other words, they are either separated at the point or surface at which the (presumed) electrical current enters, or at the surface at which it leaves the electrolyte; hence the arrangement of the elements into *electro-negative* bodies, or those which tend to the *anode*, and *electro-positive* bodies, or those which tend to the *cathode* (using the terms anode and cathode in reference to the ingress and egress of the electric influence); oxygen, the halogens, and sulphur are *anions*, or electro-negatives; hydrogen, and probably all the metals, are *cathions*, or electro-positives. A good arrangement of the elementary bodies is founded upon such properties; and although there are several whose electrical relations have not hitherto been accurately determined, the *electro-chemical arrangement* is that which will probably be most generally adopted.

CHE'NOPODIA'CEÆ. (Chenopodium, one of the genera.) A natural order of herbaceous Exogens, distinguished with difficulty from *Amarantaceæ* by their herbaceous calyx; from *Phytolaccaceæ* by their solitary carpel, and the stamens never exceeding the number of the segments of the calyx, to which they are opposite. They consist of weeds inhabiting most parts of the world, abounding least within the tropics; and they possess few sensible properties. *Chenopodium anthelminticum* produces the *wormseed oil* of the shops; but in consequence of their insipidity the species are often used for food, as in the case of spinach, &c. Chevalier has remarked the curious fact of *Chenopodium vulvaria* exhaling pure ammonia during its whole existence.

CHE'QUY, CHE'CKY, or CHE'QUERED. In Heraldry, a term used when a field or charge is divided by transverse lines, paleways and fessways, into equal parts or squares of different tinctures.

CHERT. A silicious mineral approaching the characters of flint.

CHE'RUBIM. *See* Seraphim.

CHEVA'L DE FRISE. A large and strong piece of timber, traversed with wooden spikes, pointed with iron. It is laid in a breach to impede the advance of cavalry.

CHEVALIE'R (Fr. cheval, *a horse*), is used synonymously with the Eng. knight, Lat. eques, and Germ. ritter.

CHEVRE'TTE. In Artillery, an engine used for raising guns or mortars into their carriages.

CHE'VRON. In Heraldry, one of the nine honourable ordinaries. It may be defined as consisting of the lower half of a saltire (*see* Saltire), brought to a point on the upper side; and the object from which its name is derived accurately resembles it in shape: chevron, in

old French, meaning the support of a roof formed by two rafters leaning against one another. A chevron standing on one side of the escutcheon is said to be tourny, dexter, or sinister.

CHE'VRONEL. In Heraldry, an ordinary of the same shape with the chevron, but containing only half its dimensions.

CHI'AN TURPENTINE. A species of turpentine brought originally from the island of Chios: it is the produce of the *Pistacia terebinthus*.

CHIA'RO SCURO. (It. *clear obscure*.) In Painting, the art of so disposing the lights, both positive and reflected, and the shadows of a picture in such a manner, that the objects may stand out and be naturally relieved from one another. Its name, however, seems more naturally to point to those parts of represented objects which, though in shadow, have the intensity of such shadow lessened by the reflection of a light body against them. It is a branch of the doctrine of Sciography.

CHI'CA. A red colouring matter used by some tribes of American Indians to stain the skin: it is extracted from a species of *Bignonia*.

CHI'CKEN POX. (*Varicella* of medical writers.) An eruptive disease, which, though frequently very mild in its attack, is often also violent and attended by much fever. The eruption consists of smooth vesicles of various sizes, which afterwards become whitish and straw-coloured; about the fourth day they break and scab off, seldom leaving marks, or at least not more than a few, upon the most delicate parts of the face, or where they happen to have been large or accidentally scratched or irritated. In very warm weather the fluid in the vesicles becomes yellow, and apparently purulent, so as closely to resemble small-pox in appearance; and under some circumstances the eruptive fever has not only been considerable, but preceded by delirium. The distinctive or diagnostic characters by which we distinguish chicken-pox from small-pox are,—1st, the comparative mildness of the preliminary fever, which indeed is often unobserved in strong and merry children, and nothing known of the complaint till spots are observed about the face and breast: 2d, the rapidity with which the eruption attains maturity and proceeds through its stages, the scabs forming crusts about the fourth or fifth day, which does not happen in the small-pox till the tenth or eleventh: 3d, the fluid in the vesicles is usually transparent, or only milky, whereas in small-pox it has a purulent appearance from the commencement. Like the small-pox, it very rarely attacks the same individual more than once. In the treatment of this disease little else is in most cases requisite than to keep the patient cool, to abstain from meat, to give diluents and mild aperients, and occasionally, at the commencement, a dose of calomel and rhubarb. In bad cases, the whole body is covered with eruption, in mild ones there shall only be a very few vesicles; and it not uncommonly happens that where several children have it in succession, one or two will escape with little else than slight restlessness and very trivial febrile symptoms. It is, however, by no means so trifling a disease as many writers have represented it, and if not closely watched over, may be mistaken for small-pox.

CHIEF. (Fr. chef, *head*.) In Heraldry, the upper part of the escutcheon, divided into three points, dexter, middle, and sinister. A chief, as an ordinary, is a fess removed to the upper part of the escutcheon. Charges, in the situation of the chief, are described as "in chief."

CHI'LBLAIN. An inflammatory swelling, of a purplish colour, produced by exposure of the extremities to cold: it is generally attended with itching, and often with shooting pains. Children, especially those of a scrofulous habit, and old persons, suffer most from chilblains; but they are not unfrequently produced at all times by holding the hands or feet to the fire after they have been exposed to great cold; in which case, the difference of temperature is such as actually to burn the part, for few persons are aware of the high temperature excited by the radiant heat of a common fire upon substances held near it. Warm socks and gloves are the best preventives against this affection, and the itching and pain are generally relieved by moderately stimulating applications; such as equal parts of solution of acetate of ammonia or of vinegar and spirit of wine, or of oil of turpentine and soap liniment. If the part should break or ulcerate, stimulating dressings, such as the resin or elemi ointment, are most serviceable, or in some cases mild escharotics.

CHI'LIAD. (Gr. χιλιας, *a thousand*.) An assemblage of things grouped or ranged by thousands. The word is chiefly used by the early computers of logarithmic tables, who expressed the extent of the table by saying it contained the logarithms of so many *chiliads* of absolute numbers.

CHI'LIASTS. In Ecclesiastical History, believers in the second advent of Christ to reign a thousand years on earth. *See* MILLENNIUM.

CHILOGNA'THES, *Chilognatha*. (Gr. χειλος, *a lip*, and γναθος, *a jaw*.) An order of the class *Myriapoda* or *Centipedes*, in which the two mandibles and the tongue are united together to form a large lower lip.

CHILO'MA. In Zoology, the upper lip or muzzle of a quadruped is so called when it is tumid, and continued uninterruptedly from the nostril, as in the camel.

CHI'LOPODS, *Chilopoda*. (Gr. χειλος, *a lip*, and πους, *a foot*.) An order of the class *Myriapoda* or *Centipedes*, in which the lower lip is formed by a pair of feet.

CHI'LTERN HUNDREDS, in Politics. The tract anciently called the Chiltern Hundreds extends through part of Buckingham and Oxford shires. The steward of these hundreds was an officer appointed by the crown to keep the peace there. As members of parliament, strictly speaking, cannot resign their seats, the mode of abandoning them is by accepting a nominal office (such as this stewardship) under the crown, which vacates the seat of the party taking it.

CHIMÆ'RA. In Mythology, a fabulous monster, slain by Bellerophon in Lycia. According to the lines in the *Iliad*, vi. 181. (which, however, are suspected of spuriousness), it had the head of a lion, the body of a goat, and tail of a serpent. (See Heyne's observations on this passage.) Many other forms were assigned to the Chimæra, the poets having vied with each other in representing it as the personification of all that is horrible and terrific. It has usually been depicted as vomiting forth flames:—

> —— Tremendæ
> Flamma chimæræ.—HOR. Od. IV. 2. 15.

From this fabulous story is probably derived the application of the term *chimera*, in nearly all the modern languages of Europe, to any wild or incongruous fancy arising in the mind.

CHIMÆRA. In Ichthyology, the name of a genus of Branchiostegous cartilaginous fishes; the best known species, which inhabits the northern seas, and has occasionally been taken on our own coast, is sometimes called "king of the herrings."

CHI'MNEY. (Fr. cheminée.) The place in a room where the fire is burnt, and from which the smoke is carried away by means of a conduit called a flue. Chimneys are usually made by projection from a wall, and recess in the same from the floor, ascending within the limits of the projection and recess. That part of the opening which faces the room is properly the *fire-place*, the stone or marble under which is called the *hearth*. That on a level with, and in front of it, is called the *slab*. The vertical sides of the opening are called *jambs*. The head of the foreplate resting on the jambs is called the *mantle*; and the cavity or hollow from the fire-place to the top of the room is called the *funnel*. The part of the funnel which contracts as it ascends is termed the *gathering*, or by some the *gathering of the wings*. The tube or cavity of a parallelogrammatic form on the plan, from where the gathering ceases up to the top of the chimney, is called the *flue*. The part between the gathering and the flue is called the *throat*. The part of the wall facing the room and forming one side of the funnel parallel thereto, or the part of the wall forming the sides of the funnels, where there are more than one, is the *breast*. In external walls that side of the funnel opposite the breast is called the *back*. When there is more than one chimney in the same wall, the solid parts that divide them are called *withs*. And when several chimneys are collected into one mass, it is called a *stack of chimneys*. The part which rises above the roof for discharging the smoke into the air is called a *chimney shaft*, whose horizontal upper surface is termed the *chimney top*.

The *covings* were formerly placed at right angles to the face of the wall, and the chimney was finished in that manner; but Count Rumford showed that more heat is obtained from the fire by reflexion when the covings are placed in an oblique position. He likewise directed that the fire itself should be kept as near to the hearth as possible, and that the throat of the chimney should be constructed much narrower than had been practised, with a view to prevent the escape of so much heated air as happened with wide throats. If the throat be too near the fire, the draught will be too strong, and the fuel will be wasted; and if it be too high up, the draught will be too languid, and there will be a danger of the smoke being occasionally beat back into the room. Before Count Rumford directed his attention to this subject, smoky chimneys were very common; but by studying his principles, these at present seldom occur. *See* FIREPLACE, GRATE, STOVE.

CHIMPANZEE, CHIMPANSE, or QUIMPESE'. Native names of the African orang (*Simia troglodytes*, Blum.). It is of a black colour, and attains the height of between four and five feet, measured in a straight line from the vertex to the heel. This species, which of all the brute creation approaches nearest to man, has been hitherto brought alive to this country only in a young state, and a knowledge of the osteological structure of the adult has been but very recently acquired.

It differs from the Asiatic or red Orang not only in colour, but in the greater size of the external ears, the

more prominent ridge above the eyes, the relative shortness of the arms, and the greater development of the thumb of the hind foot, which has constantly two phalanges and a nail.

The principal osteological differences are the following: — The cranium is flatter and broader in proportion to the face. The supraciliary ridges are more developed; and the great interparietal and lambdoidal crests, which render so remarkable the skull of the adult orang, are wanting. The interorbital space is broader. The occipital foramen has a more central position. The anterior condyloid foramen is single on each side, while in the orang it is double. The intermaxillary sutures are obliterated before the deciduous incisors are shed. The incisive and canine teeth are of smaller proportional size. There are thirteen pairs of ribs instead of twelve pairs, as in the orang; and consequently there are thirteen dorsal vertebræ. The sternal bones form a single row. The chimpanzee further differs from the orang-utan in the non-division of the pisiform bone of the wrist; and in the depression at the head of the femur, corresponding to the interarticular ligament of the hip-joint, which is wanting in the orang.

The habits and deportment of the chimpanzee, as observed in those young specimens which have been brought alive to this country, are of peculiar interest, from the high degree in which inquisitiveness, perception, memory, and docility are manifested; and by the gravity and consideration with which many even of its ludicrous and playful actions are performed. It is probable, however, that in the adult much of this intelligence gives way to the fiercer traits of the brute nature. The negroes which inhabit the forests in the interior of Africa have a general, and doubtless well-founded dread of the great black ape. Vague accounts are repeated in succeeding systems of natural history of the gregarious habits of the chimpanzee; its policy, as shown in the construction of rude huts, and other but much less probable feats. The truth is, however, that we have much more certain knowledge of the habits of the duck-billed platypus of Australia than of the adult chimpanzee, which is the most interesting of all the Mammalia, from the close approach which it makes to the human species.

CHI'NA ROOT. The root of the *Smilax China*, so called because imported from China. It was formerly used in the same cases in which sarsaparilla is now given.

CHINCHI'LLA. The generic appellation founded on the South American or local name "chinchille," or "little chinche," and applied to a genus of gnawing Mammalia or Rodents, peculiar to the South American continent. It is from a species of this genus (*Chinchilla lanigera*) that the grey fur is obtained, which has been so much prized in Europe for many years; but the exact nature of the animal itself has been only very recently ascertained, by the examination of specimens which have been procured for the menagerie of the Zoological Society.

CHI'NCOUGH. *See* WHOOPING COUGH.

CHINE'SE ARCHITECTURE. *See* ARCHITECTURE.

CHINTZ. A peculiar pattern upon printed calicos, in which flowers and other devices are printed in five or six different colours, upon white and coloured grounds. A good chintz pattern in fast colours is one of the most surprising and difficult efforts of the art.

CHIRA'GRA. (Gr. χειρ, *the hand*, and αγρα, *a seizure.*) Gout in the hands.

CHI'ROGRAPH. (Gr. χείρ, and γράφω, *I write.*) In Diplomatics, a species of instrument contrived for the purpose for which indentures were devised; viz. the enabling different parties to retain authenticated counterparts of the deed. Some word (commonly the word *chirographum*, whence the name) was written between the two copies on the same sheet, and cut through lengthwise when they were divided.

CHIRO'LOGY. (Gr. χείρ, and λόγος, *discourse.*) The language of the fingers; sometimes called *dactylology*, from δάκτυλος, *the finger.*

CHI'ROMANCY, or PALMISTRY. (Gr. χείρ, and μάντεια, *divination.*) The imaginary art of divination by the lines of the hand. According to the science of Chiromancy, the lines on the palm of the hand are divided into principal and inferior: the former are five — the line of life; the line of the liver, or natural mean; the line of the brain; the thoral line, or line of fortune; the dragon's tail, or discriminal line, between the hand and the arm. Various other modes of divination were practised by observation of the hand and its parts; onychomancy (from onyx, a nail), dactylomancy (from the fingers), &c. The practice of chiromancy, once defended and explained by grave and learned authors, is now chiefly left to be exercised by the gipsies.

CHIRO'NOMY. (Gr. χείρ, and νόμος, *law.*) The science which treats of the rules of gesticulation, or pantomime, and oratorical action.

CHI'TON. (Gr. χιτων, *a garment.*) The name of a genus of Gastropodous Mollusks, which have a series of testaceous symmetrical pieces implanted in the back part of the mantle.

CHI'VALRY. (From the French chevalier, *knight.*) The usages and customs pertaining to the order of knighthood. The general system of manners and tone of sentiments which the institution of knighthood, strictly pursued, was calculated to produce, and did in part produce, during the middle ages in Europe, is comprehended in ordinary language under the term of chivalry. This imaginary institution of chivalry, such as it is represented in the old romances, had assuredly no full existence at any period in the usages of actual life. It was the ideal perfection of a code of morals and pursuits which was in truth only partially adopted; and bore the same relation to the real life of the middle ages, which the philosophical excellence aimed at by the various sects of antiquity bore to the real conduct of their professors. But, in both instances, a system of abstract perfection was propounded in theory, which, although the defect of human nature prevented it from being reduced into practice, yet exercised a very important influence in modelling the minds, and even controlling the actions, of those who adopted it. The vivifying principle of ancient philosophy was ideal virtue; that of chivalry, the ideal point of honour.

The origin of chivalry has often been traced to the German tribes; nor has its spirit ever penetrated very deeply into the usages of any country in which these tribes have not either produced the ancestors of the great body of the nation, or at least the conquering and governing class, which transfused its habits and sentiments into that body. Thus Germany and France, and England, whose gentry derive their origin from both, have been the countries most distinguished for the prevalence of this institution. The martial spirit of the Spaniards was indeed partly animated by it; but in their country it always bore something of the character of a foreign importation, modified by the circumstances of their juxtaposition with the Arab race. In Italy, it existed only among those classes which imitated the manners of France and Germany, and never entered into the general character of the natives, notwithstanding the popularity of the poetical romances of chivalry. Among the Sclavonic nations it has never prevailed extensively; although the feudal constitution of Polish society derived a certain tincture from it, it never penetrated into Russia. It has been often remarked, that it is only within the last two or three generations that the nobility of that country, by their intercourse with the nations of Western Europe, have derived something of the spirit of the chivalrous code, so far as it still subsists among ourselves: the point of honour, and its peculiar concomitant the usage of the duel, were scarcely known in Russia before the present century.

Chivalry originated in the feudal attachment of warriors to the person of their king or chief, which has been so often described as characteristic of the ancient Germans. Hence the English word knight, which, when the Norman "chevaliers" were first known among us, was spontaneously used as the translation of their title, signifies in its origin our "knit," or attached to another, — a servant or attendant. At what precise time the devotional character was added to the original martial impress of national usages, and the compound system of chivalry were thus produced, it is not easy to ascertain. It has been said that the investiture of the knight was purely military until the reign of Charlemagne; and it may be supposed that the wars of the Franks against the Saracens first blended the ardour of war and religion together, and that the Crusades completed the union. At the latter period were instituted the two celebrated military orders of monks, the Templars and Hospitallers (see those articles), the code of whose government combined monastic and knightly usages. After valour and devotion, the third characteristic feature of chivalry was gallantry to the fair sex; and the source of this sentiment also has been traced to the habits and feelings of the Northern tribes, among whom woman was looked on with a much more exalted sense of her dignity than in the most civilized countries of antiquity. It is needless to add, that this romantic feeling, however high its precepts may have sounded in theory, degenerated into licentiousness in actual life. M. de Sainte Palaye, the learned French historian of the usages of chivalry, has brought instances enough to prove the extreme depravation of manners which prevailed, even in those courts and at those periods in which the spirit of chivalry was most prevalent. If the Crusades communicated to chivalry its devotional character, it is in the poetry of the Troubadours about the same period, in the 12th and 13th centuries, that we find its peculiarity of devotion to the female sex first developed. But in their verses it does not appear clothed with the romantic purity with which it was afterwards invested by the writers of the heroic tales of chivalry; and still less in those of the contemporary French writers of the *Fabliaux*, from whose compositions we draw the most authentic monuments which we possess in this curious branch of antiquarian research. The knight, or even the esquire, was bound to follow a single lady and dedicate himself to her service; but little delicacy is either

intimated or enjoined in the relations which subsisted between them, and his devotion to her was considered as entitling him to every recompence love could bestow.

The 14th century was the brilliant period of chivalry; when its usages, originally formed in the manners of the people, had become fixed and embellished by the fictions of the writers of romances; and when princes and chieftains, forming their idea of the institution rather from the descriptions contained in them than from real life, sought to bring back their courts and camps to the likeness of those ideal models of perfection. It may be more truly said that the romances of chivalry were the prototypes of that state of courtly society which existed in the reigns of our Edward III. and Richard II., and of which Froissart has left us such accurate and lively representations, than that existing manners and sentiments furnished the subject-matter of those romances. These fictions, of which the heroes were taken from among a long list of fanciful personages, in whose history a little tradition of past events was blended with a much larger proportion of fable, represented the knight not only as devoted to the service of his religion, his lord, and his mistress, but also as consecrated to the general service of the oppressed and maintenance of right all over the world. There can be little doubt that the peculiar ceremonies which, in the 14th and 15th centuries, accompanied the creation of a knight,—the vow of chivalry, the watching, prayer, and fasting, &c.—were borrowed by romantic imaginations from such fabulous recitals, which were read and related in every courtly company. In the reign of Edward III., the romantic part of chivalry, as we have said, was more closely transfused into real manners than at any period either preceding or subsequent. Before that period, the manners of the knights and dames had exhibited but little of that polish and refinement, their sentiments but little of that generosity, which were the subjects of so much imaginary description; and, in later times, chivalry gradually decayed. Its usages were maintained with even more of magnificence than before; its various rites, titles, and distinctions subsisted for a long period in most European countries, and partly remain to this day; but the spirit of feudal devotedness was quenched by the multiplication of mercenary troops; adherence to a feudal lord was superseded by the more general feelings of national patriotism (which, singularly enough, was almost wholly omitted in the chivalric code), and the extravagances into which the imaginary point of honour had led its votaries fell into discredit and ridicule.

It is, therefore, to the 14th century, and especially to that part of its chronicles preserved by the true annalist of chivalry, Froissart, that we must look for the period when the line between real society and that represented in romances was most nearly broken down. When the usages of chivalry were most flourishing, all men of noble birth (except the highest) were supposed to pass through three orders or gradations. They first lived as pages in the train of nobles and chiefs of high rank; next, as esquires, they attached themselves to the person of some individual knight, to whom they were bound by a strict law of obedience, and for whom they were bound to incur every danger, and, if necessary, sacrifice their lives; and, thirdly, they were promoted to the rank of knighthood. (For the different orders of knighthood see KNIGHT.) It is sufficient to observe here, that however great the distinction might be between knights in point of rank and wealth, custom established a species of equality among all of the same order, which may be said to subsist among gentlemen of the present day. They formed, all over Europe, a common corporation, as it were, possessing certain rights, and owing each other certain mutual duties and forbearances. They were united, not by the ties of country, but by those of feudal obedience, which attached every knight to the banner of his liege lord, from whom he held his fee; but little or rather no dishonour attached to knights who were under no such feudal tie, if they chose their own chieftain wherever they thought fit: they were free adventurers, whose order was a passport in every service; and, in the actual conflict, the hostility of knights was moderated by usage. Thus, it was dishonourable in any knight to take a knight's life if disarmed, and not to set him free when a prisoner on receiving a fitting ransom. Manny and Chandos, the two most celebrated of Edward III.'s knights, were attached wholly to the banner of their sovereign, and not to that of their country; and although the French constable Dugueselin, the third among these mirrors of chivalry, appears to have been devoted to the cause of France as well as that of his master, this double loyalty found few imitators. In peace, also, knights of all countries were welcome visitors at the courts of chivalric sovereigns; and all enjoyed the privilege of presenting themselves at the tournament, and contending there for the prize.

With regard to the point of honour, which forms the most important feature in the usages of chivalry, see some details under the article DUEL. The principal objects to which it related were, religious belief; fealty to the feudal superior; devotion to some one selected lady; and, finally, the general character for honour and courtesy which it was incumbent on a knight to maintain; for although his imaginary duties, as a knight errant, to avenge wrong and succour the oppressed on every occasion, were not of course very strictly put in practice, yet his vow to perform those duties attached to his character a certain degree of sacredness which it was necessary to maintain. Chivalrous honour was chiefly supported in two ways: first, by the single combat or duel, whether on account of serious provocation or by way of trial of strength; secondly, by the performance of vows, often of the most frivolous and extravagant nature. These latter were generally undertaken for the honour of the ladies. Many historical instances of these absurd yet daring follies are preserved by Froissart. They, with other usages of knighthood, were long preserved among those who aimed at the reputation of chivalry, after these usages had ceased to form a part of the ordinary customs of society. Thus, the instances which Froissart relates of knights riding alone up to the barriers of fenced cities, &c., were imitated in after times, and at no less personal hazard, by such romantic personages as Lord Herbert of Cherbury, whose feats performed in rivalry with the French champion Balagny are mentioned in his Memoirs. But the vows did not only relate to martial achievements, but to others of a more extravagant and grotesque character. We need only refer to Monstrelet's narrative of the company called "Galois" of knights and ladies, who bound themselves, for love of each other, to follow a particular code of usages; of which a part consisted in wearing thick clothes in summer and thin in winter, to show that the power of their love rendered them insensible to the difference of seasons; a vow which was maintained with such perseverance, that the greater part of the devoted company actually died of cold. (See also the *History of the Vow of the Heron Sainte Palaye*, vol. iii.) The commencement of such extravagances, however, was rather a sign of the decline of the true spirit of chivalry. It decayed with the progress of mercenary armies and the decline of feudal institutions through the 15th century; in the 16th, it was little more than a lively recollection of past ages, which knights such as Bayard and sovereigns such as Francis I. and Henry VIII. strove to revive; and, finally, it became extinguished amid religious discords, leaving as its only relic the code of honour, which is still considered as governing the conduct of the gentleman.

CHLA'MYPHORE, *Chlamyphorus*. (Gr. χλαμυς, *a cloak*, and φερω, *I carry*.) A name given to a small species of Armadillo, which is covered by its coat of mail as by a cloak. The animal is not above 6 inches long, and, like the rest of its genus, inhabits exclusively the continent of South America. It is interesting from the analogy of its skeleton and coat of mail to those of the gigantic extinct megatherium.

CHLENA'CEÆ. (Gr. χλαινα, *a cloak*. All the names belonging to this order are compounded of this word, used in a figurative sense for an involucrum.) A natural order of shrubby or arborescent Exogens, allied to *Malvaceæ*, on account of their monadelphous stamens and involucrated flowers, but referred by Jussieu to the vicinity of *Ebenaceæ;* it, however, appears, from their imbricated calyx, regular flowers, and albumen, that they have the greatest affinity with *Cistaceæ*. They are all natives of Madagascar; beautiful in their flowers, but of no known use; and are, in fact, but little known even to botanists.

CHLO'RAL. (From the first syllables of *chlorine* and *alcohol*.) A liquid composed of chlorine, carbon, and oxygen, obtained by the action of chlorine upon alcohol.

CHLORANTHA'CEÆ. (Chloranthus, one of the genera.) A small natural order of apetalous Exogens, nearly allied to *Saururaceæ* and *Piperaceæ;* from both of which it differs in wanting a sac to the embryo, and in having a pendulous ovule and opposite leaves with intermediate stipules. Blume places these plants near to *Opercularineæ*. They are natives of the hotter parts of the world, and appear to possess stimulating properties of great importance. *Chloranthus officinalis* and *brachystachys*, although not officinal in Europe, are believed to be among the most powerful of stimulating agents.

CHLO'RATES. Combinations of chloric acid with salifiable bases. Of these salts the *chlorate of potash* is best known; it was formerly called *oxymuriate of potash*. When mixed with combustibles, such as sulphur or charcoal, and some of the metals, it forms highly explosive compounds, which ignite by a blow or by friction, or upon the contact of sulphuric acid. A mixture of this salt with sugar, or with sulphuret of antimony, is used for tipping the *matches* which inflame when dipped into sulphuric acid, or when briskly drawn through a piece of emery paper. Chlorate of potash consists of 76 chlorine acid + 48 potassa = 124 of the chlorate.

CHLO'RIDES. Combinations of chlorine, corresponding with the oxides. Common salt is a *chloride of sodium;* that is, a binary compound of chlorine and sodium. Where there are two chlorides of the same

base, the relative proportions of chlorine in them are almost invariably as 1 to 2; hence the terms *protochloride* and *bichloride*. Calomel and corrosive sublimate are the protochloride and bichloride of mercury. The latter is frequently termed *perchloride*. In calomel 200 of mercury are combined with 36 of chlorine, and in corrosive sublimate with twice 36 or 72.

CHLO'RINE. (Gr. χλωρος, *green*.) This gas was discovered in 1774 by Scheele, who called it *dephlogisticated muriatic acid*; the French nomenclaturists afterwards termed it *oxygenated muriatic acid*, conceiving it to be a compound of oxygen and muriatic acid. This erroneous view of its nature was corrected in 1809 by Sir H. Davy, who gave it the present name, indicative of its colour. Chlorine is a simple substance, existing at common temperatures and pressures in the gaseous state; but when subjected to a pressure of about four atmospheres it becomes condensed into a yellow transparent liquid, which is a non-conductor of electricity. 100 cubical inches of chlorine, at mean temperature and pressure, weigh between 76 and 77 grains: water absorbs twice its volume, and acquires a yellow colour, and the peculiar suffocating odour of the gas. When humid chlorine is exposed to a temperature of 32°, it assumes a crystalline form; this *hydrate of chlorine* consists of 1 equivalent of chlorine $= 36 + 10$ of water $= 9 \times 10$ or 90. Chlorine is not only unrespirable, but very injurious when breathed, even if largely diluted: a taper burns in it with a red smoky flame, and is soon extinguished. Some of the metals, when finely divided, spontaneously take fire in chlorine, such as brass leaf, or powdered antimony. A remarkable property of chlorine is its power of destroying almost all vegetable and animal colours; hence the important application of this gas and of some of its combinations to the *art of bleaching*. It also destroys the putrid odour of decomposing vegetable and animal substances, and infectious effluvia of all kinds, whence its use in fumigation, and in preventing the spread of infectious and contagious matter, and purifying noxious atmospheres.

The great natural source of chlorine is *common salt*, which contains it in the proportion of about 60 *per cent*. It is procured by decomposing common salt by the joint agency of sulphuric acid and peroxide of manganese. The best proportions are 3 parts of salt and 1 of oxide of manganese; these are well mixed, and put into a retort with 2 parts of sulphuric acid previously diluted with 2 of water. Chlorine is evolved, and its extrication is quickened by the application of a gentle heat. Chlorine may also be obtained from a mixture of muriatic acid with half its weight of black oxide of manganese. The gas may be collected over water, and should be preserved in bottles with glass stoppers; if left in the contact of water, it is soon absorbed. *See* Muriatic Acid.

CHLORI'ODINE, or CHLORIO'DIC ACID. A compound of chlorine and iodine.

CHLO'RITE. (Gr. χλωρος.) An earthy mineral of a *green* colour, often found in the cavities and veins of slate rocks.

CHLO'RO. (Gr. χλωρος.) A term used in the composition of botanical and other scientific words formed from the Greek, to indicate a clear lively green colour without any mixture.

CHLO'ROCARBO'NIC ACID. A compound formed by exposing a mixture of chlorine and carbonic oxide to the action of light.

CHLO'ROCYA'NIC ACID. A compound of chlorine and cyanogen.

CHLORO'METER. (Gr. χλωρος, and μετρον, *a measure*.) An instrument for the purpose of testing the decolouring or bleaching powers of *chloride of lime*, by which the relative values of different samples of that important bleaching and disinfecting compound may be ascertained.

CHLO'ROPHAITE. (Gr. χλωρος, and φαιος, *black*.) A mineral, which when recently broken is green, but afterwards becomes black.

CHLO'ROPHANE. (Gr. χλωρος, and φαινω, *I shine*.) A species of fluor spar, which, when heated, shines with a beautiful pale green light.

CHLOROPHYLL. (Gr. χλωρος, and φυλλον, *a leaf*.) The green colouring matter of the leaves of plants.

CHLORO'SIS (Gr. χλωρος), or ETIOLATION. In Botany, is a species of constitutional debility; the affected individual being pale, and destitute of a healthy green: the stems are weak, long, and slender; no flowers are produced; and the plant is readily killed. It is believed that this malady is exclusively produced in plants by want of sufficient light.

Chlorosis. (Gr. χλωρος.) In Medicine, a disease giving a peculiar sallowness to the countenance, hence called the *green sickness*. It chiefly affects young females; its symptoms are extremely various, but generally referable to imperfect or suppressed menstrual evacuation. Tonics, chalybeates, aloetics, sea and cold bathing, and slight electric shocks passed through the pelvis, together with due amusement and exercise, are among the principal remedial agents.

CHLO'ROXA'LIC ACID. A compound obtained by exposing acetic acid and chlorine to bright sunshine. Its elements are in such proportion, that it may be regarded as a compound of 1 equivalent of hydrochloric acid and 1 of oxalic acid.

CHLO'RURETS. Compounds of chlorine. *See* Chlorides.

CHO'ANITES. (Gr. χοανη, *a funnel*.) A genus of extinct Zoophytes, so called on account of their fossil skeleton or polypary presenting in general a funnel-shaped figure, though sometimes they are globular or subcylindrical. This genus holds an intermediate place between *Alcyonium* and *Ventriculites*: it is distinguished from the former by having a central cavity at the upper part, and from the latter by not having an outer reticulate surface. One species, the *Choanites königii*, is found in abundance in the loose flints beneath the turf near the race course at Lewes in Sussex, and appears to have been common in the upper beds of the chalk.

CHO'COLATE. A term said to be compounded of two Indian words, choco, *sound*, and alta, *water*, from the noise made in its preparation. Chocolate is made by triturating the roasted cocoa nut into a paste in a heated mortar, sugar and some aromatics being occasionally added; the oily matter of the nut gives it whilst hot a due consistence, so that it is cast in tin moulds, in which it concretes, on cooling, into cakes. It is a rich article of diet, and apt to disagree with weak stomachs.

CHOIR. (Gr. χορος.) In Architecture, the part of a church in which the choristers sing divine service. In former times it was raised separate from the altar, with a pulpit on each side, in which the epistles and gospels were sung, as is still the case in several churches on the Continent. It was separated from the nave in the time of Constantine. In nunneries, the choir is a large apartment, separated by a grate from the body of the church, where the nuns chant the service. This term is used also in music to signify a band of singers in different parts.

CHOKE DAMP. A term applied by well-diggers and miners to *carbonic acid gas*.

CHO'LAGOGUE. (Gr. χολη, *bile*, and αγω, *I evacuate*.) A term applied by ancient medical writers to certain purgative remedies which produce bilious evacuations.

CHOLE'DOCHUS. (Gr. χολη, and δεχομαι, *I receive*.) One of the ducts of the liver is called the *ductus communis choledochus*.

CHO'LERA. (Gr. χολη, and ῥέω, *I flow*.) A disease accompanied by vomiting and purging, with great pain and debility, and apparently arising from excess or acrimony of bile: it is most common at the close of summer and beginning of autumn, and seems to be produced by cold, suppressed perspiration, indigestible fruits, &c. It generally commences with a sense of pain about the bowels, fever, thirst, an irregular pulse, and severe vomiting and purging of bilious matter: in favourable cases these symptoms subside in a few days with the aid of opiates, mucilaginous diluents, and mild aperients followed by tonics; but in severe cases great exhaustion ensues, attended by depression of spirits, anxiety, hurried respiration, cold sweats, hiccup, low and fluttering pulse, and the patients rapidly sink, and are sometimes carried off within twenty-four hours. In such cases warm fomentations sometimes relieve the pain, and effervescent saline draughts check the sickness, and enable the stomach to bear large doses of opium.

Cho'lera, Asia'tic. The term *Asiatic* or *Spasmodic Cholera* has been applied to a new and most appalling form of pestilential disease, which seems to have been but indistinctly known prior to the year 1817. It made its appearance in August that year at Jessore, after having previously raged to a formidable extent in the south of Bengal, and thence it spread over a great part of Asia, carrying off millions of human beings. In 1823 it broke out at Astracan, but did not at that time extend further into Russia; in 1828, however, it appeared at Orenburg, and during the autumn of that year and the spring of 1829 it spread over a considerable part of the Russian dominions. It raged at Moscow in September, 1830; and having been apparently carried by the Russian army into Poland, it propagated itself through different parts of Europe, and reached this country. The symptoms of this, as of other disorders, vary considerably at different times and in different individuals; but as our object here is briefly to describe the characteristic features of the disease in their unalloyed form, we shall omit all unnecessary details, and place before our readers a short account of its effects in its worst and by no means uncommon form.

The first circumstance that strikes us in regard to the attacks of this disease is their suddenness. A person in apparent health feels slightly giddy, chilly, or sick, and in the course of two or three hours sinks into a state of extraordinary and alarming debility; the countenance assumes a deadly paleness, and the skin feels and looks like that of a corpse; the pulse falls, flutters, and is al-

most imperceptible; a livid circle surrounds the sunken eyes; the tongue is slightly furred, and the breath cold. Under this excessive and extraordinary prostration the patients sometimes die in the course of a very few hours; otherwise it is succeeded by vomiting and purging, the voided matters resembling turbid whey, and being in fact a serous fluid with floating shreds or flocculi of coagulated albumen; and now cramp assails the extremities, and afterwards the abdomen, producing spasms of varying but sometimes of extreme violence; great pain and heat about the region of the stomach, and intolerable weight and anguish round the heart are complained of, with much thirst and anxiety; the voice faulters, and the unfortunate sufferer asks frequently, in plaintive and broken whispers, for cold water; the secretions of urine, bile, and saliva appear, in this state of things, as if entirely suspended; the evacuations have a singular fœtor, and the breath and perspiration have that peculiar odour which announces the rapid approach of death. Towards the close of this horrid scene, the respiration becomes very slow, the tendons of the extremities quiver, the sufferer is unable to swallow, insensibility succeeds, and after one or two long and convulsive sobs he dies. The mind, even at last, is scarcely ever much disturbed; but towards the close the patient sinks into a state of apathy, and appears desirous of being left to his fate. Attacks of this kind generally prove fatal in from four to eight hours.

If from this extreme case we turn to what may be termed milder forms of the disease, the same general train of symptoms are observed; but they are less rapid in their succession, and there is more time and opportunity to resort to the resources of art. The attack begins with sickness or purging, succeeded by uneasiness and heat about the pit of the stomach; the matters which are thrown off from the stomach and bowels gradually assume the appearance of rice water; the countenance shrinks; the constriction of the thorax and cramps and spasms follow; and in the course of twenty-four to thirty-six hours the patient dies, in many instances delirious or comatose.

Those who survive seventy-two hours generally recover, as far as the primary symptoms are concerned; the spasms and difficulty of breathing give way, the natural warmth of the body is restored, and the pulse returns to something like its natural standard. The most favourable symptoms are sleep, perspiration, return of the secretion of urine and of bile, accompanied by proportionate improvement in the pulse and aspect of the features; but, even under these apparently and really favourable symptoms, fever of a low or continued character may ensue, — it indeed sometimes immediately follows the blue stage or collapse; and if not relieved by a critical perspiration on the second or third day, the pulse quickens, the face is flushed, there is drowsiness and suffusion of the eyes, stupor, a foul mouth, and other symptoms of mixed or typhus fever, which terminate fatally from the fourth to the eighth day, or even later, in those very individuals who had been saved in the first or cold stage.

The appearances observed on dissection of those who died within eight or ten hours were, a relaxed and pale state of the stomach and intestines; absence of bile and of fæces in the intestines; an empty and contracted bladder; congestion in the venous circulation of the large vessels; the gall-bladder full of bile, but not passing into the intestine. In more protracted cases other appearances occasionally occurred, more especially serous effusion upon and in the brain, with congestion of the vessels, and other usual appearances of febrile disease. In all cases the blood presents a more or less morbid appearance, and is often of a very dark colour and increased consistence, so as to have been compared to tar.

The pathology of cholera is as yet most imperfectly understood; nor has it been satisfactorily ascertained whether it is or is not contagious; the general opinion, however, is in favour of its contagious nature, and there cannot be the least doubt of the propriety of enforcing the most rigid precautionary measures founded upon such an opinion.

Details respecting the *medical treatment* of cholera would be out of place in this work; and the plans to be pursued vary so much with circumstances, as to render it impossible to condense into small limits a general view of this important subject.

Emetics are among the earliest measures which should be put in practice; they should be such as act certainly and rapidly, and conjoined with stimulants, such as essential oils and capsicum. *Blood-letting* has been adopted by many practitioners in the early stages of the disease. Its favourable effect is to cause the pulse to rise; if it produce faintness, it must be immediately put a stop to, and should be followed by the application of warm air, and other dry warmth. Large doses of calomel, with or without opium, are resorted to to remove local congestion, and especially to stimulate the liver; and these means are assisted and the general powers of the system kept up by ether, ammonia, brandy, and volatile oils, in such quantities and forms as the particular circumstances of the respective cases may point out. If the irritability of stomach continues, flannels soaked in very hot water, and then sprinkled with oil of turpentine, should be applied to the region of the stomach and abdomen.

The great object of all those remedies applicable to the first stage of the disease is to enable the system to rally from its depressing effects, to bring about re-action, and to stimulate the nervous and vascular systems; but then the utmost circumspection is required in reference to the injurious effects which this plan will induce, if carried too far. Here, however, the symptoms are usually those of typhoid or continued fever, and are to be treated accordingly, great attention being always paid to the state of the biliary and urinary secretions, and to the evacuations from the bowels.

Besides the treatment founded upon the above outline, other and very dissimilar plans have been adopted, founded upon the change which the blood appears to suffer in this disease. It has been by some presumed that in all cases of cholera, the saline matters of the blood, along with a large quantity of its water, are thrown off by the intestines, constituting the characteristic serous discharge above adverted to; and that the residuary blood becomes thick and black, in consequence of the deficiency of its salts. Dr. Stevens therefore proposed the administration of large doses of common salt, occasionally mixed with nitre and chlorate of potash; and from this plan the best effects have, according to some, resulted, while in the hands of others it has entirely failed. The truth is, that in the worst attacks of the disease the approach of death is so quick that there is scarcely time for any thing to take effect; and where it is less rapid, the symptoms must guide the treatment: amongst these it must be confessed that there are seldom any which would justify the prudent practitioner in drenching the bowels with salt and water.

But the bolder advocates of what has been termed the *saline treatment* of cholera have gone a step further, and have dared to inject saline solutions into the veins: how far such extraordinary means are justifiable, will appear from the following statement. (*Pereira, Elements of Materia Medica*, part i. 313.) "This plan was, I believe, first practised by Dr. Latta. (*Med. Gaz.* x. 257.) The quantity of saline solution which has been in some cases injected is enormous, and almost incredible. In one case 120 ounces were injected at once, and repeated to the amount of 330 ounces in twelve hours. In another, 376 ounces were thrown into the veins, between Sunday at eleven o'clock A.M. and Tuesday at four P.M.; that is, in the course of fifty-three hours, upwards of 31 pounds, The solution used consisted of two drachms of muriate and two scruples of carbonate of soda to 60 ounces of water. It was at the temperature of 108° or 110° Fahr. In another series of cases 40 pounds were injected in twenty hours; 132 ounces in the first two hours; 8 pounds in half an hour! The *immediate* effects of these injections, in a large majority of cases, were most astonishing; — restoration of pulse, improvement in the respiration, voice, and general appearance, return of consciousness, and a feeling of comfort. In many instances, however, these effects were only temporary, and were followed by collapse and death."

The reports as to the ultimate benefit of this treatment in cholera are so contradictory, that it is difficult to form a correct estimate of it. "That it failed in a large proportion of cases after an extensive trial, and greatly disappointed some of its stanchest supporters, cannot be doubted. Dr. Griffin states that all the published cases of injection which he can find recorded amount to 282, of which 221 died, while 61 only recovered; but he thinks that the average recoveries from collapse by this method of treatment far exceeded the amount of any other treatment in the same district and under the same circumstances." (*Med. Gaz.* xxii. 319.)

A vast quantity of matter has been published in reference to the history, symptoms, and treatment of pestilential cholera. Among those works upon the subject, the general reader may consult the following with advantage; namely, the Reports published by order of Government under the superintendence of the Medical Board; *History of the Epidemic Cholera, by B. Hawkins, M.D., &c.; Mr. Bell's Letter to Sir H. Halford; the Report of Drs. Russell and Barry; Dr. James Copland on Pestilential Cholera;* and a paper in the Ninety-first Number of the *Quarterly Review* for November, 1831.

CHOLE'STERINE. (Gr. χολη, and στερεος, *solid.*) The matter which forms the basis of most gall stones.

CHONDRO'LOGY. (Gr. χονδρος, *a cartilage*, and λογος, *a discourse.*) The history of cartilages.

CHO'NDROPTERY'GIANS, *Chondropterygii.* (Gr. χονδρος, *a cartilage*, and πτερυξ, *a fin; gristly-finned.*) The name of Cuvier's last order of fishes, characterized by the gristly nature of all the spines which support the fins. The whole internal skeleton in this order is cartilaginous.

CHORA'GIC MONUMENT. (Gr χορος.) In

Grecian Architecture, a monument erected in honour of the Choragus who gained the prize by the exhibition of the best musical or theatrical entertainment at the festivals of Bacchus. The Choragi were the heads of the ten tribes at Athens, who overlooked and arranged the games at their own expense. The prize was usually a tripod, which the victor was bound publicly to exhibit, for which purpose a building or column was usually erected. The remains of two very fine monuments of this sort, viz. those of Lysicrates and Thrasyllus, are still to be seen at Athens.

CHORD. (Gr. χορδη, *the string of a lyre.*) In Music, a combination of two or more sounds heard contemporaneously, forming a concord or a discord between them.

Chord. In Geometry, is the straight line which joins the two extremities of the arc of a curve; so called from the resemblance which the arc and chord together have to a bow and its string, the chord representing the string. The chord of an arc is equal to the size of half the arc; hence, to find the length of the chord of any given arc, multiply the diameter by the sine of half the arc. Tables of chords are given in some of the older works on trigonometry; but they have been superseded by the tables of sines, which are much more convenient for trigonometrical calculations.

CHOREA. (Gr. χορος, *a chorus;* the ancient accompaniment to dancing.) The disease commonly called *St. Vitus's dance.* It shows itself by convulsive motions of the limbs, face, head, and trunk, varying extremely in extent and violence; the speech is often more or less affected, and frequently the mental energies become grievously impaired. It is most common in early life, as from the age of ten or twelve to puberty; and makes its approach gradually in persons chiefly of debilitated constitutions: the appetite is generally ravenous at first, and the bowels costive; various convulsive motions then ensue, and only cease during sleep, which, however, is seldom sound. This is one of those diseases which require especial attention in its early stages, and which even in its slightest forms, when once habitual, is very difficult to manage. The leading treatment consists in the judicious administration of aperients and brisk purges, so as to clear the stomach and bowels thoroughly of all irritating matters; the constitution may at the same time be strengthened by tonics and chalybeates, with occasional stimulants; and some of the more urgent spasmodic symptoms may be sometimes cautiously encountered by opium, camphor, henbane, and ether. Cold bathing also has its advantages when circumspectly resorted to; and the mind must be diverted by change of air and scene. The diet should be very regular, nutritive, and never in excess. In this complaint much will depend upon the exertions of the patient himself, who, though relieved of the more urgent symptoms, will often retain relics of his disorder through a long life.

CHO'REPI'SCOPI. (Gr. χωρα, *a country place*, and επισκοπος, *a bishop.*) Country bishops; persons appointed by the bishops in the early periods of Christianity to superintend the rural districts which appertained to their dioceses, but which were at an inconvenient distance from the city in which they abode themselves. The class of chorepiscopi is represented as holding a middle rank between the bishops and the presbyters.

CHO'RION. (Gr. χωρα, *a receptacle.*) The external membrane which envelopes the *fœtus in utero*, between which and the amnion there is a gelatinous fluid. Its interior surface is smooth, but exteriorly it is shaggy and vascular.

CHORO'GRAPHY. (Gr. χωρα, *district*, and γραφω, *I describe.*) The description of a district, in contradistinction to geography (the description of the earth or of countries) and topography (the description of particular spots)

CHO'ROID MEMBRANE OF THE EYE. The second tunic of the eye lying under the sclerotic, with which it has a vascular connection: it commences at the optic nerve, and passes forward with the sclerotic to the beginning of the transparent cornea, where it firmly adheres to the sclerotic by a cellular membrane, forming a white fringe called the *ciliary circle;* it then recedes from the sclerotic and cornea, forming a round coloured disc called the *iris*, and its posterior surface is termed *uvea.* The choroid membrane is very vascular, and its external stellated vessels are called *vasa verticosa.* Its internal surface is covered by a *black pigment.*

CHO'ROID PLE'XUS. A plexus of blood-vessels situated in the lateral ventricles of the brain.

CHO'RUS. Gr. χόρος.) A band of singers and dancers who performed odes in honour of the gods, particularly Bacchus. The chorus formed an important part of the Greek tragedies and early comedies, which were interspersed with odes. There were likewise several other choruses besides these, as the Dithyrambic; and the exhibition of these was one of the public burthens imposed on the richest private citizens of Athens. It was called the choregia (χορηγία). *See* Drama, and Choragic Monument.

Chorus. In Music, the joint performance of music by the whole of the members of the orchestra.

CHOU'ANS. In French History, the royalist insurgents on the right bank of the Loire during the revolution when the Vendeans rose on the left, were thus popularly named; according to some, from the cry of the screech-owl (*chat-huant*), an imitation of which was a signal during their nightly meetings. They were for the most part brigands, and their object rapine rather than civil war. After the revolution of 1830, they made a transient reappearance in the neighbourhood of Nantes and Le Mans.

CHREMATI'STICS. (Gr. χρηματα, *wealth.*) The science of wealth; a name given by Continental writers to the science of political economy, or rather to what in their view constitutes a portion of the science. They consider political economy as a term more properly applicable to the whole range of subjects which comprise the material welfare of states and citizens, and chrematistics (by which they mean nearly the same science which M'Culloch and most other English writers describe as political economy) as merely a branch of it. See especially M. de Sismondi, *Etudes sur l'Economie Politique.* See also Chrysology.

CHRESTO'MATHY. (Gr. χρηστος, *useful*, and μανθανω, *I learn.*) According to the etymology, that which it is useful to learn. The Greeks frequently formed commonplace books by collecting the various passages to which, in the course of reading, they had affixed the mark χ (χρηστος). Hence books of extracts chosen with a view to utility have received this name.

CHRISM. (Gr. χρισμα, from χριω, *I anoint.*) The oil which is used both in the Greek and the Roman churches in the administration of baptism, confirmation, ordination, and extreme unction.

CHRI'STENDOM. A word sometimes employed in such a sense as to comprehend all nations in which Christianity prevails: more commonly, all realms governed under Christian sovereigns and institutions. Thus European Turkey, although three fourths of its inhabitants are Christians, is not in ordinary language included within the term Christendom. The history of the fortunes of Christianity, in respect of its geographical extension, presents remarkable periods of advance and decline. After the conversion of Constantine, and the gradual decay of Paganism, Christianity continued to spread, but chiefly in the direction of east and south, for more than three centuries, the barbarian conquerors of the Roman provinces soon adopting it. About the middle of the seventh century, Christendom comprehended Europe south and west of the Rhine and Danube; Africa north of the Great Desert; Abyssinia; parts of Nubia; Asia to the Euphrates; Armenia, and part of Arabia; and that small colony in southern India which subsists to this day. The Saracen power rose by conquest from this extensive empire. In little more than a century, Christendom was deprived of nearly all its Asiatic provinces, of which the faithful inhabitants were reduced to a tributary condition: of the whole of northern Africa, in which they were exterminated or converted: and of Spain. Sicily, the latest conquest of the Saracens, was occupied by them about 830. But just at the same epoch, or that of lowest decline, Charlemagne began to extend the limits of Christendom in the north; and the second period of advance extends through the 9th, 10th, and 11th centuries, in which "the reign of the gospel and the church was extended over the north: Bulgaria, Hungary, Bohemia, Saxony, Denmark, Norway, Sweden, and Russia." (*Gibbon*, chap. 55.) From that time to the 16th century, Christianity gradually reconquered Spain on the one hand; while, on the other, the newly arisen power of the Turks wrested from it the remainder of its Asiatic territories and the European provinces of the Greek empire. Since that period no important changes have taken place in the relative extent of Christendom and Islamism; but the vast continent of America, as far as it has been colonized, has been added to the former, and the rapid increase of its communities in numbers and civilization has greatly enhanced their comparative importance. The number of Christians inhabiting Europe and America, and scattered in the other parts of the globe, may perhaps be estimated conjecturally as follows:—

Roman Catholic church -	- 144,000,000
Reformed churches -	- 60,000,000
Greek and other Oriental churches	- 66,000,000
	270,000,000

CHRISTIA'NITY. The religion of Jesus Christ. From the period when the disciples "were called Christians first in Antioch" (Acts, xi. 26.) down to the present day, the main doctrines of the gospel, and the great moral principles which it reveals and confirms, have been preserved without interruption in the church. But notwithstanding this substantial unity, it cannot be denied that the character of the religion has been very materially coloured throughout all its history by the circum-

stances and genius of different nations and ages. The first marked forms of opinion which acquired consistency among the general body of Christians tended in two very different directions. The *Judaizing* Christians clung to the ordinances of the elder religion, and strove to teach the separation from it as slightly as possible; under the names of Nazareans, &c., they existed as late as the 4th century, but ceased after the first to exercise any very extensive influence on the church. The *speculative* Christians placed figurative interpretations both on the external facts and mysteries of the religion, or sought to connect it with the philosophical and theurgical systems of the ancient world. Apollos of Alexandria was the first teacher, it is commonly said, who introduced this speculative tendency into Christianity; and St. Paul, while he does not condemn Apollos, dwells on the evils produced by those who from his teaching deduced as it were a separate body of doctrine (1 Cor. iii.). In this way arose,—1. The early heretics the Nicolaitanes and followers of Cerinthus, and the Gnostics, professors of the "knowledge falsely so called" (ψευδώνυμος γνῶσις) of St. Paul. 2. At a later period, the Manichæans, who imported into Christianity the notion of the rival principles of good and evil, which continued for many ages to possess adherents. 3. Within the church itself, the *Alexandrian school of theology*, which has exercised a more permanent influence. This school, in the second and third centuries, became partially tinged with the sentiments of Platonic philosophy; and was characterized by the acute and refining spirit of the East. Like the Gnostics, its chief doctors encouraged the notion of a mystical or second meaning in the revelations of the faith, of which the key was in the possession of the learned only (Clemens, Origen, &c.). In the mean time, the main body of believers, comparatively unaffected by the influence of science and speculation, was gradually acquiring new views of a different and more positive character. During the first three centuries after the apostolical times, the opinions respecting the authority of the priesthood, attachment to forms and ordinances, the honour paid to individual purity of life (and especially to constancy under persecution), gradually and steadily increased and strengthened. In the West, and particularly in Africa, these tendencies became peculiarly strong. The Montanists, Donatists, and Novatians separated successively from the church, on the score of its defection from an imaginary standard of personal purity; and when Africa began to have a school of theology of her own (Tertullian, Cyprian, and others, to Augustine), this was the direction of its labours. In that theology all is dogmatical, nothing speculative. Every thing is taken in its most literal and naked sense: God himself is not personal only, but invested almost with the attributes of a human agent. Both doctrines and ordinances are as definite as possible, and the utmost rigour of practice enjoined. The history of the African church affords a momentous commentary on their strainings after imaginary perfection. After two centuries of discord and decay from the time of Augustine, it was not only subdued but obliterated by the first assault of the Mohammedans. The early heretics had entertained theoretical notions respecting the inferiority of Christ to the Father; but the Arians, in the last half of the 3d century, were the first to preach it as the doctrine of the church, and seek to confirm it by appeal to antiquity. The council of Nice (A. D. 325) condemned this opinion; and by the concurring declarations of bishops from all parts of Christendom afforded the strongest testimony to the fact, that the Catholic sentiment of the church had always been opposed to it. But the Arians, and other sects differing from the church by various shades of opinion on the same subject, continued to subsist until the 6th century, during which these controversies partly died away in the West, amidst the misery and barbarism of the age, and partly were extinguished by the authority of the church. It was thus that the governors of the church were first driven to protect its fundamental doctrines by reducing them to formal propositions embodied in creeds and the canons of councils (especially the six Œcumenical or general, which were held from A. D. 381 to 680). Thus, in the West, speculation was effectually subdued. In the East, it still lingered in vain but refined distinction respecting the nature and relations of the persons of the Trinity (the Nestorian, Monophysite, and Monothelite heresies). Meantime a new and most important feature of Christianity was developing itself. A solitary believer, who left the world and retired into the deserts of Egypt (Antonius, A. D. 311), set an example which was followed by innumerable Christians with a fervour alike contagious and irresistible. The calamities of the empire, and the wretched state of society, seem to have aided the mistaken tendencies of devotion in producing this carelessness of life and its duties. It is scarcely possible to exaggerate the evils produced by the spirit of monachism in the 4th and 5th centuries: the contempt for all the social habits and social virtues; the ferocious zeal, sometimes venting itself against Paganism and sometimes against brethren; the unregulated, wandering, untameable disposition which it engendered, and which the spirit of the age dignified with the title of celestial piety. Whatever Christianity may owe to the great fathers of the church, Augustine, Ambrose, Jerome, Basil, Chrysostom, we must not forget the encouragement which they all administered to this destructive error, far more mischievous than any of the heresies which they combated. At length, when the evils of this anarchical system had become almost intolerable, arose the lawgivers of monachism in the West. Benedict (A. D. 529), and still more Cassiodorus, strove to bring religious persons under a temperate and liberal rule of government: their attention was called to what they had hitherto despised as secular pursuits, especially agriculture and literature, together with a more regulated piety; and thus monachism, which in a time of declining civilization had powerfully accelerated decay, became, in a time of barbarism, an agent of preservation and improvement. In A. D. 716, the separation between the Greek and Western churches, which had long been provoked by the gradual usurpations of the Roman bishop over the latter, became really complete through the controversy respecting images, although not formally acknowledged until the middle of the 11th century. This era is important, as those corruptions of Christianity which, according to Protestants, disfigure both the Greek and Roman Catholic churches are evidently anterior to it,—those peculiar to the latter posterior. Thus, the honour paid to saints, relics, &c., the adoration of the Virgin Mary (which seems to have been partly a result of the Nestorian controversy), monachism, &c., are common to both, and therefore ancient: the exclusively Roman tenets, transubstantiation, papal infallibility, purgatory, &c., are accounted by Protestants comparatively modern doctrines, to which the whole church has never agreed; while celibacy, which the Roman pontiffs with great difficulty succeeded in imposing on the whole clergy in the 11th century, is observed in the Greek church only by the higher dignitaries. For several centuries after this separation, the external history of Christianity in the West presents us with little more than the vicissitudes and disputes of monastic orders, the strife of ecclesiastical dignitaries with each other and with temporal sovereigns, the growth of superstitious observances among the laity, the union of the religious with the military spirit, and the increasing power of the pope; yet, under all these disadvantages, the impartial observer may discern the great principles of religion still preserved, and still working beneath the surface of society for its gradual purification. The 12th century was a period of revival in the West, both in point of learning and religion. The military spirit of devotion found ample employment in the crusades. The rise of the scholastic philosophy (A. D. 1100) gave a new and peculiar character to the study of theology. Among the lower classes a powerful spirit of religious reform began rapidly to extend itself, especially in Italy and the south of France. A strictness of life amounting almost to asceticism, a revolt rather against the wealth and temporal supremacy of the clergy than their doctrines, were the first characteristics of the reforming sects; but to these was soon added an addiction to mystical tenets and observances. The Cathari, Waldenses, Albigenses, &c. all partook more or less of these common peculiarities; but how far they had really adopted, if at all, those Manichæan opinions (derived through the medium of the Paulicians, a sect which long subsisted in the East) with which they were charged by their opponents, will probably never be ascertained. These sectaries, in their hostility to the Catholic priesthood, had to a great extent usurped their province as religious advisers of the poor and uninstructed with prayer, preaching, and even auricular confession. It was this peculiar form of the impending danger which induced the church (after it had openly condemned the new doctrines) to give ample encouragement to the institution of the *Mendicant orders* (in the beginning of the 13th century), one of the most important events in the history of Christianity. These bodies met the sectaries on their own ground, by the assumption of asceticism, poverty, and the popular practices which had availed the former. They were also employed by the church in the sterner task of putting down by force heretical opposition, and completed the extirpation of the Albigenses begun by the sword of the Crusaders. But they extended their hostility to learning and science, and to all the established institutions of the time, and became as much hated by the secular priesthood (or parish clergy, so called in distinction to those who have renounced the world and are bound by monastic rule, called regulars), and by the old and wealthy orders, as by the heretics themselves. Under the influence of persecution the development of the age was checked. From the middle of the 13th century to the end of the 14th the church of Rome met with little opposition from sectaries, and underwent little change in respect of doctrine and discipline; but during the same

period the increasing power of princes, the long removal of the seat of papal power from Rome, and various other causes, sensibly diminished its temporal authority. In the next century, the same causes continued to act, while the revived energy of reforming sects (Lollards, Hussites, &c.) and the rapid spread of literature and learning proved still more hostile to its spiritual power. Thus the way was prepared for the great events of the Reformation. To trace the history of Christianity from that period onwards, would be impossible within our present limits. It may be sufficient to direct the reader to the general outline of the most marked events, omitting those of a nature merely political or ecclesiastical. *In the Roman Catholic church*, the definite establishment of her doctrines by the council of Trent, which met A.D. 1546; the foundation of the order of Jesuits, its rapid increase in power and influence, and the gradual decline of the other monastic orders; the rise, progress, and condemnation of Jansenism in France, in the 17th and 18th centuries; the suppression of the Jesuits, in 1773, and overthrow of other monastic orders in France at the revolution, —an example since followed in other countries; the revival of the Jesuits, 1814. *In Reformed countries*, the early division of Protestants into Lutheran and Calvinist, besides many subordinate sects; the foundation of the church of England under Edward VI., partaking in some degree the character of the two; the rapid advance of Calvinism and kindred opinions in the 17th century in England, Holland, and Scotland; their decline in the first of these countries by the re-establishment of the church in 1660, and the prevalence of Arminian sentiments within it, and on the Continent by a gradual tendency to a more liberal system of theology; the establishment of the three confessions (Roman Catholic, Lutheran, and Reformed or Calvinist) on an equal footing in Germany by the peace of Westphalia, 1648; the gradual approach of Protestant, especially Lutheran, divines towards what has been called the rationalist system of religion in the last part of the 18th century; the rise of Methodism in England, and of cognate systems on the Continent; the union effected by the present king of Prussia and other German sovereigns between the Lutheran and Calvinistic bodies in their respective dominions.

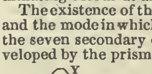
CHRISTIAN KNOWLEDGE, SOCIETY FOR PROMOTING. This society was founded in the year 1699 for the objects which the name imports. It promotes these objects principally by the diffusion of religious and moral tracts. It has also circulated vast numbers of copies of the Bible and Testament, and of the Book of Common Prayer and other authorized expositions of faith. It is entirely supported by the established church, and is a powerful engine for the instruction of the people in the principles of that body.

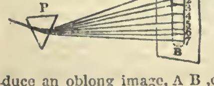
CHROMA'TIC. (Gr. χρωμα, *colour*.) In Music, the introduction of semitones between each of the tones in the diatonic scale.

CHROMA'TICS. (Gr. χρωμα.) That part of optics which treats of the colours of light and of natural bodies. This is a very important branch of physical science, and one which of late years has been prosecuted with great assiduity. Until Newton undertook his memorable experiments on the refraction of light, the cause of the different colours of bodies had never received any satisfactory explanation: such, indeed, was the difficulty which the ancients attached to this subject, that Plato considered it to be an usurpation of the rights of the Deity to attempt the investigation of this mystery of nature. The discovery of the difference of refrangibility in the coloured rays of the solar spectrum afforded a clue to the solution of the problem; and Newton demonstrated, by a series of decisive experiments, that colour depends not on any modification of light acquired by reflection or refraction, but is inherent in the light itself; the solar beam being composed of rays of all the colours contained in the spectrum, which are differently affected in passing through refracting media. This hypothesis of the existence of different species of luminous molecules is founded on the other hypothesis, that light is a substance emitted from the sun or luminous body, and is indeed a necessary consequence of that theory; for if colour depended merely on a difference of the masses, or of the initial velocities of the particles, it would follow that the dispersion of the rays, in passing through a prism, would always be proportional to the refraction, which, as is well known, is contrary to experience.

Colours of the Solar Spectrum. — Let a beam of solar light be admitted through a small aperture in the window shutter of a darkened room, and it will form on the opposite wall, or on a screen, a circular image of the sun. But if a prism, P, be interposed, the refracted beam, instead of forming a bright white spot, will produce an oblong image, A B, called the solar spectrum, the sides of which are terminated by two vertical straight lines, and the ends by semicircles. This lengthened image consists of *seven* principal colours, which melt into each other by insensible gradations; namely, *red*, *orange*, *yellow*, *green*, *blue*, *indigo*, and *violet*, arranged in the order now written, the red being at the lower end B. Newton, by whom this experiment was first performed, conceived these to be produced by so many distinct species of homogeneous light co-existing in the solar beam, and that all other shades of colour are produced by blending them together in certain proportions. As it is impossible to define the limit at which one colour ends and another begins, and as the spectrum is in fact composed of an infinite number of different shades, the above division is entirely arbitrary. Another observer of the phenomenon for the first time would probably have fixed on a greater or smaller number. Newton, it appears, was influenced by a fanciful idea that an analogy, or rather identity of ratios, subsists between the divisions of the spectrum formed by the seven colours which he assigned to it, and those of the musical scale. But the resemblance which suggested this analogy to Newton was purely accidental, and depended, as has since been found, on the nature of the substance of which his prism was formed; for though the colours are invariably arranged in the same order, they expand very differently, according to the nature of the refracting substance; and, consequently, the relative magnitudes of the spaces which they occupy in the spectrum are entirely altered. Tobias Mayer, in an essay, *De Affinitate Colorum* (Opera inedita, 1775), regards all colours as arising from three primitive colours, *red, yellow, blue*. But a mixture of red and green in certain proportions produces a colour which, so far as the eye can judge, is perfectly identical with the yellow of the spectrum; and a mixture of green and violet also produces a perfect blue: hence it was suggested by Dr. Young that the innumerable shades of the spectrum are all compounded of *red*, *green*, and *violet*. Sir David Brewster, however, inferred from experiments on the absorption of light in passing through coloured media, that green and violet are both compound colours, separable by prisms of coloured glass; and he adopts the hypothesis of Mayer, that the three simple homogeneous colours are red, yellow, and blue. He supposes the solar spectrum to consist of three spectra of equal lengths; a *red* spectrum, a *yellow* spectrum, and a *blue* spectrum. The primary red spectrum has its maximum of intensity about the middle of the red space in the solar spectrum; the primary yellow, about the middle of the yellow space; and the primary blue has its maximum between the blue and the indigo space; the two minima of each of the three spectra coinciding at the two extremities of the solar spectrum. From this view of the subject it follows that *red, yellow*, and *blue* light exist at every point of the solar spectrum; and that as a certain portion of red, yellow, and blue constitutes white light, the colour of every point of the spectrum may be considered as consisting of the predominating colour at any point mixed with white light.

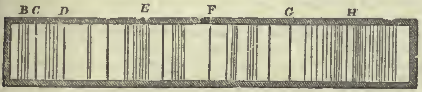
The existence of three primary colours in the spectrum, and the mode in which they produce by their combination the seven secondary or compound colours which are developed by the prism, are illustrated by Sir D. Brewster as follows: — Let M N be the prismatic spectrum consisting of three primary spectra of the same lengths, M N, viz., a red, a yellow, and a blue spectrum. The red spectrum has its maximum intensity at R; and this intensity may be represented by the distance of the point R from M N. The intensity declines rapidly to M and slowly to N, at both of which points it vanishes. The yellow spectrum has its maximum intensity at Y, the intensity declining to zero at M and N; and the blue has its maximum intensity at B, declining to nothing at M and N. The general curve which represents the total illumination at any point will be outside these three curves, and its ordinate at any point will be equal to the sum of the three ordinates at the same point. Thus the ordinate of the general curve at the point Y will be equal to the ordinate of the yellow curve, which we may suppose to be 10; added to that of the red curve, which may be 2; and that of the blue, which may be 1. Hence the general ordinate will be 13. Now, if we suppose that 3 parts of yellow, 2 of red, and 1 of blue make white, we shall have the colour at Y equal to 3+2+1, equal to 6 parts of white mixed with 7 parts of yellow; that is, the compound tint at Y will be a bright yellow, without any trace of red or blue. As these colours all occupy the same space in the spectrum, they cannot be separated by the prism; and if we could find a coloured glass which would absorb 7 parts of the yellow, we should obtain at the point Y a white light, which the prism would not decompose. (*Brewster's Optics*, in *Lardner's Cyclopædia*, p. 74.)





Dark Lines in the Spectrum.—One of the most curious, and, with reference to the theory of light, one of the most important optical discoveries of modern times, is the

existence of a great number of dark lines, or fixed rays, in the solar spectrum, parallel to one another, and perpendicular to its length. These dark lines were first perceived by Dr. Wollaston; but it was Fraunhofer, a celebrated optician of Munich, who first accurately described the phenomenon, and pointed out the uses to which it could be applied. In order to perceive these lines, considerable management is necessary. The prism employed must be perfectly free from veins, and the light must enter and emerge from it at equal angles; it is necessary also to employ a telescope. They are distributed very unequally through the spectrum, and the whole number amounts nearly to 600. Seven groups, which are more



easily perceived than the others, and which are distributed over the principal colours of the spectrum, have been distinguished by Fraunhofer by the letters B, C, D, E, F, G, H. Of these B is in the red space, near its outer end. C, which is a single line, and blacker than others contiguous to it, is near the limit of the red next the orange. D is in the orange, and near the yellow; it is composed of two lines of equal darkness very close to each other, and is easily distinguished. E is in the green, and consists of seven or eight rays. F is in the blue, G in the indigo, and H in the violet. Besides these there are several other very remarkable groups, particularly one in the green, between E and F, which is composed of three strong lines. The circumstance which renders the discovery of these lines extremely important is, that they always preserve the same relative positions in respect of the boundaries of the coloured spaces; and though their distances vary with the nature of the prism by which they are produced, their number and order remain absolutely invariable, so long as the light proceeds from the same source. For an account of the spectra formed by different lights, see *Brewster's Optics*, p. 87.

Colours of Natural Bodies. — The separation of light into different colours by refraction having been established as an optical fact, a different task remained, viz. that of showing in what manner refraction could take place so as to produce the permanent colours of natural bodies. Newton proved that the colour of any body is not the result of any quality inherent in that body, or in the particles by which it may be tinged, but is merely a property of the light in which they happen to be placed. The peculiar colours of bodies are only exhibited in a white light. If they are viewed by simple and homogeneous light of any colour, they appear of the colour of that light and no other. Thus, the leaf of a plant, for example, which in the white light of day appears green, if illuminated by homogeneous *red* light, appears *red;* if by homogeneous *yellow* light, *yellow*, and so on. Hence we conclude that one body is red, and another violet, because the one is *disposed* to reflect the red or least refrangible rays, and the other the violet or most refrangible. But the difficulty consists in explaining the cause of this *disposition* or transient condition of the body, which renders it fit to reflect rays of one colour and absorb those of another. Newton has attempted, in his *Treatise of Optics*, to refer it to the constitution or elementary structure of bodies. The principles or propositions on which his theory are founded are the following:— 1. Bodies that have the greatest refractive powers reflect the greatest quantity of light; and at the confines of equally refracting media there is no reflexion. 2. The least parts of almost all natural bodies are in some measure transparent. 3. Between the particles of bodies are many pores or spaces, either empty or filled with media of less density than the particles. 4. The particles of bodies, and their pores or spaces between the particles, have some definite size.

Upon these principles, Newton thus explains the origin of *transparency*, *opacity*, and *colour*. Transparency he considers as arising from the particles and their intervals or pores being too small to cause reflexion at their common surfaces, so that all the light which enters transparent bodies passes through them without any portion of it being turned from its path by reflexion. Opacity in bodies arises, he thinks, from an opposite cause; viz. when the parts of bodies are of such a size as to be capable of reflecting the light which falls on them, in which case the light is stopped or stifled by the multitude of reflexions. The colours of natural bodies have the same origin as the colours of thin plates or soap bubbles; their transparent particles, according to their several sizes, reflecting rays of one colour and transmitting those of another. For if a thinned or plated body, which, being of an uneven thickness, appears all over of one uniform colour, should be slit into threads, or broken into fragments of the same thickness with the plate or film, every thread or fragment should keep its colour; and, consequently, a heap of such threads or fragments should constitute a mass or powder of the same colour which the plate exhibited before it was broken; and the parts of all natural bodies being like so many fragments of a plate, must, on the same grounds, exhibit the same colour. (See *Newton's Optics*, book ii.; or *Brewster's Life of Newton*, p. 81.)

Such are the general principles of the Newtonian theory of colours; but there are numerous classes of phenomena, some of which were known in the time of Newton, but many more which have been discovered since, of which they fail to afford any explanation, and to which, indeed, they are wholly inapplicable. The ingenuity of its warmest supporters has not yet been able to explain by this theory the total absence of all reflected light from the particles of transparent coloured media, such as coloured gems, coloured glasses or fluids, &c. For these reasons, and many others depending on optical phenomena not connected with colours, philosophers have of late years manifested a disposition to abandon the theory of the emission of light, and to return to that of Huygens, who supposed light to be produced by the vibrations or undulations of an ethereal fluid of great elasticity, which pervades all space and penetrates all substances. *See* LIGHT.

Without entering into the subject of the propagation of light, it may be sufficient to remark, that the ordinary phenomena of colours may be explained on the principle of absorption. Every substance, how opake soever it may be, transmits light, at least through a very small thickness; thus gold when reduced into thin leaf is translucent. From this fact it is assumed as a principle, that every particle of ponderable matter has the faculty of absorbing or extinguishing a determinate fraction of the luminous rays which fall on it or pass very near it, the remainder being reflected or transmitted. This fraction varies with the colour or species of colour of the incident luminous rays, and with the nature of the particle. For light of the same colour we may suppose it constant, whatever be the number of incident rays: so that the intensity of a homogeneous light, which has traversed a diaphanous plate composed of equidistant particles of the same nature, will diminish in a geometrical, when the thickness of the plate increases in an arithmetical, progression. White light falling on the surface of an opake body is not totally reflected at the surface, for, as has been just remarked, no substance is perfectly opake: a portion of the incident light therefore penetrates the superficies of every body on which it falls, and is reflected by particles beneath the surface, and, in consequence of this interior reflection, is again emitted from the medium. But whilst the ray is thus penetrating and escaping from the body, the different colours of which it is composed suffer unequal absorptions; and on the totality of these absorptions depends the compound colour of the reflected ray, or the natural colour of the body. In this manner are explained the effects produced by coloured glasses, the blue colour of the sky, and the various tints of great masses of water.

The phenomena of the colours of thm lamina, as soap bubbles, plates of mica, and of striated and grooved surfaces, are among the most difficult of explanation; and it is here that the undulating theory, which accounts for them by the *interference* of the light reflected from the second surface of the plate with that reflected from the second, possesses its greatest advantage. For further information on this subject, see the terms INTERFERENCE, LIGHT, REFRACTION.

CHROMIUM. (Gr. χρωμα, *colour.*) A metal discovered by Vauquelin in 1797. It exists chiefly in two native compounds; the one formerly called *red lead* of Siberia, which is a *chromate of lead;* the other, a compound of the oxides of chromium and iron. Chromium is a whitish, brittle, and very infusible metal; sp. gr. 5·5. When heated with nitre it is converted into *chromic acid.* Its equivalent number is 28. It forms two compounds with oxygen,—a green oxide, and a red peroxide; the latter being sour, and combining with salefiable bases, is called *chromic acid.* The oxide consists of 28 chromium + 12 oxygen; and chromic acid of 28 chromium + 24 oxygen. Chromic acid is of a red colour, and forms a variety of *coloured* compounds, some of which are much used in the arts; such as the *chromate* and *bichromate of potash*, largely manufactured for the use of calico printers, and the *chromates of lead*, employed as yellow and red dyes and paints. The oxide of chroma is green, and furnishes a valuable colour for porcelain and in enamel. Chromic acid gives colour to the ruby, and the green of the emerald is due to oxide of chroma.

CHRO'NIC. (Gr. χρονος, *time.*) Diseases of long duration are termed *chronic*, in opposition to those of more rapid progress, which are called *acute*.

CHRO'NICLE. In Literature, an historical register of events in the order of time. Most of the historians of the middle ages were chroniclers who set down the

events which happened within the range of their information, according to the succession of years.

CHRO'NICLES. The name of two books in the canon of scripture. They consist of an abridgment of sacred history from its commencement down to the return of the Jews from the Babylonish captivity, and are called by the Septuagint παραλειπομενα (lit. things omitted), because they contain many supplemental relations omitted in the other historical books. It has been generally supposed that the Chronicles were compiled by Ezra, though circumstances are not wanting to diminish the probability of this conjecture. Eichhorn (*Einleitung*, vol. ii.) gives as his reasons for attributing them to Ezra their similarity in point of style, idiom, and orthography to the books of Kings and Ezra; while the opponents of this view base their opinion on the discrepancies that occur throughout Chronicles and Kings, in regard to facts, dates, numbers, names, and genealogies. (For a learned exposition of this subject, see the *Penny Cyclopædia*, and the authorities there referred to.)

CHRO'NOGRAM. (Gr. χρονος, *time*, and γραφω, *I describe.*) An inscription comprehending a date, which may be read by selecting all or some of the numeral letters, which are frequently written in these curious trifles in larger characters than the rest; as,

"ChrIstVs DVX ergo trIVMphVs."

(A medal of Gustavus Adolphus.) Sometimes united with an anagram; as one in honour of General Monk,

"GeorgIVs MonCe DVx de AumarLe;".

which may be read,

"Ego Regem reduxi, Ano. Sa. MDCLVV."

CHRONO'LOGY. (Gr. χρονος, and λογος, *discourse.*) Literally, the doctrine of time: is the science which treats of the various divisions of time, and of the order and succession of events.

In order to ascertain and register the intervals of time between different events, two things must necessarily be assumed: — 1st, An epoch or fixed point in time to which all events, whether preceding or succeeding, may be referred; and 2nd, A measure or definite portion of time, by which the intervals between the fixed epoch and other events may be estimated. Of these the first is entirely arbitrary, and the second arbitrary to a certain extent; for though certain periods are marked out by the recurrence of natural phenomena, a choice of these phenomena must be made. It is on account of the arbitrary nature of these two elements, on which all chronological reckoning depends, that so much confusion and uncertainty exist respecting the dates of historical events.

The diversity of epochs which have been assumed as the origin of chronological reckoning, is a natural consequence of the manner in which science and civilization have spread over the world. In the early ages the different communities or tribes into which mankind were divided began to date their years each from some event remarkable only in reference to its own individual history, but of which other tribes were either ignorant, or regarded with indifference. Hence not only different nations, but almost every individual historian or compiler of annals, adopted an epoch of his own. Events of local or temporary interest were also constantly occurring in every community which would appear of greater importance than those which were long past, and consequently be adopted as new historical dates. The foundation of a monarchy or a city, or the accession of a king, were events of this class; and accordingly are epochs of frequent occurrence in the ancient annals. Religion also came in to increase the confusion caused by political changes. Soon after the introduction of Christianity, the various sects began to establish eras, commencing with events connected with the appearance of Christ; but no regard was given to uniformity. In like manner, the Mohammedans employ dates having reference to the origin of their faith. All these circumstances have conspired to render it a task of extreme difficulty for modern historians to ascertain the order of the political occurrences of ancient times.

But it is not merely the number of chronological epochs and the various origins of eras that have caused the perplexity; the measure by which long intervals were compared varied in different countries, and in different ages, and hence arises another source of confusion in arranging the order of time. In the scripture history, the lapse of time is frequently estimated by generations or reigns of kings. Some of the historians of early Greece reckoned by the succession of the priestesses of Juno; others by that of the ephori of Sparta; and others again by the archons of Athens. Even when the length of the solar year began to be used as the measure of time, uniformity was not obtained. The length of the solar year is a fixed element in nature, and liable to no variation. But neither the commencement or termination of the year is marked by any conspicuous sign. Its precise length can only be ascertained by a long-continued series of astronomical observations. Rude nations were therefore unacquainted with it; and even when it had become known with considerable accuracy, it was still necessary to form a civil year, and adapt it to the seasons, the solar year not being composed of an exact number of days. Most nations had recourse to intercalations (*see* CALENDAR) for this purpose. The ancient Egyptians followed a purely solar year, which consisted of exactly 365 days. Its commencement, therefore, fell one day earlier with respect to the seasons every four years, and in the period of about 1460 years would successively fall on every day in the year, and a whole year be gained in the reckoning. The civil year of the Jews, the Greeks, and many other nations, was regulated partly by the sun and partly by the moon, which rendered its adjustment still more complicated and difficult. The Mohammedan year is purely lunar; and we can only pass from their calendar to the *Gregorian*, which is used in Christian countries, by first finding the number of days from the commencement of their era to any given event, and then turning them back into Gregorian years. (*See* HEGIRA.) The Chinese, Hindoos, and some other Asiatic nations, have epochs and methods of reckoning peculiar to themselves.

For these reasons, and numerous others that might easily be adduced, it is very seldom that the precise interval between the events mentioned in ancient history and modern dates can be determined with any degree of certainty, and great discrepancies exist among the computations of different chronologers. A remarkable instance of this occurs with regard to the computations made to determine the epoch of the creation of the world from the scripture history. Desvignoles, in the preface to his *Chronology of Sacred History*, mentions that he had collected upwards of two hundred different calculations, the shortest of which reckons only 3483 years between the creation and commencement of the common era, and the longest 6984; the difference being no less than thirty-five centuries. The most important works on chronology are, *Usher's Annales Veteris et Novi Testamenti; Newton's Chronology; Blair's Chronology and History of the World; Playfair's Chronology; Tables Chronologiques de l'Histoire Ancienne et Moderne*, by Thouret; and above all others, *L'Art de Verifier les Dates.*

CHRONO'METER. (Gr. χρονος, *time*, and μετρον, *measure.*) A watch of peculiar construction, and great perfection of workmanship, used for determining geographical longitudes, or other purposes where time must be measured with extreme accuracy. The chronometer differs from the ordinary watch in the principle of its escapement, which is so constructed that the balance is entirely free from the wheels during the greater part of its vibration; and also in having the balance compensated for variations of temperature. Marine chronometers generally beat half seconds, and are hung in gimbals, in boxes about six or eight inches square. The pocket chronometer does not differ in appearance from the ordinary watch, excepting that it is generally a little larger. Chronometers are of immense utility in navigation; and ships going on distant voyages are usually furnished with several, for the purpose of checking one another, and also to guard against the effects of accidental derangement in any single one. The accuracy with which some of the better sort of chronometers have been found to perform is truly astonishing; the error in a two months' voyage not exceeding two or three seconds.

CHRY'SALIS. (Gr. χρυσος, *gold.*) The second state of a Metabolian or changeable insect, in which it becomes inactive, takes no food, and is inclosed in a transparent covering, which in many instances reflects a metallic lustre; whence the name.

CHRY'SOBA'LANA'CEÆ. (Chrysobalanus, one of the genera.) A natural order of shrubby or arborescent Exogens, chiefly inhabiting the hotter parts of the world. They are very nearly related to *Rosaceæ*, from which they differ in having a style proceeding from the very base of the ovary, and irregular stamens and petals. The species are of little importance. The fruit of *Chrysobalanus icaco* is eaten in the West Indies under the name of the cocoa plum, and that of some others is used in other countries in a similar way.

CHRYSO'BERIL. This mineral occurs in small rounded masses, and in crystals; it is very hard, transparent or translucent, and of different shades of greenish yellow. It is employed in jewellery. It has been brought from Brazil; and is associated in the sand of the Ceylonese rivers with rubies and sapphires. The *cymophane* of Hauy, which is a species of chrysoberil, consists of alumina 76·7, glucina 17·8, oxide of iron 5·5.

CHRYSOCHLORE. (Gr. χρυσος, *gold*, and χλωρος, *green.*) A species of mole, *Chrysochloris capensis*, inhabiting the Cape of Good Hope, the fur of which reflects most brilliant metallic hues of green and gold.

CHRYSOCO'LLA. The Greek name for borax.

CHRYSO'GRAPHY. (Gr. χρυσος, *gold*, and γραφω,

I write.) The art of writing in letters of gold: a sumptuous fashion, practised by the writers of manuscripts, chiefly in the early part of the middle ages, when the leaves of parchment which contained the writing were also dyed with purple and other colours.

CHRY'SOLITE. (Gr. χρυσος, and λιθος, *a stone.*) A crystallized mineral, often of a golden yellow colour. It is a ferriferous *silicate of magnesia*, and is sometimes used in jewellery.

CHRYSO'LOGY. (Gr. χρυσος, *gold*, and λογος, *discourse.*) A name by which some Continental writers distinguish that branch of political economy which relates to the production of wealth.

CHRYSO'MELA. (Gr. χρυσος, *gold*, and μελας, *black.*) The name of a Linnæan genus of Coleopterous insects, now the type of an extensive group, divisible into three families; viz. the *Chrysomelidæ* proper, characterized by having the antennæ remote from each other at the base; *Cassididæ*, having the antennæ arising close together, but concealed at the base by the thorax; and *Galeracidæ*, having the antennæ close together at the base, but not concealed by the thorax. The characters which these three families possess in common are, a small body of an oval or rounded form; antennæ seldom so long as the body; legs of a moderate length, but rather thickened; and tarsi with the three basal joints dilated and spongy beneath, forming a kind of cushion. The insects of the present tribe are of sluggish habits, and feed upon the leaves of various vegetables, both in the larva and imago state, being characterized in the latter period by their brilliant metallic tints; whence their name. The larva of one of the British species (*Eumolpus vitis*, Fabr.) preys upon the young buds and leaves of the vine, and by its attacks upon the footstalk of the grape bunch so injures the nutrient vessels, as to cause the destruction or deterioration of the fruit. In the wine countries of Europe the ravages of this insect are often very serious, and much dreaded.

CHRY'SOPRASE. (Gr. χρυσοπρασος.) A pale green silicious mineral, generally semitransparent. It is tinged by oxide of nickel, and much esteemed for ornamental purposes.

CHURCH. (Gr. κυριακον, from κυριος, *Lord.*) A building dedicated to the Lord. The word *church*, however, is not confined to this signification, but answers to all the senses in which ἐκκλησια (Fr. église) is used in the New Testament, which, from its original meaning of a *convened assembly*, is employed, 1st, to denote the whole body of true believers, or the visible church; 2nd, in addition to these, the spirits of the just made perfect, or the invisible church; 3rd, any congregation of Christians met together in a single place, or the body of believers resident in a town or district; and 4th, the edifice in which they meet for divine worship. To these we may add a fifth sense of the modern term church, when it is applied to a distinct religious community; as the Romish, the English, the Lutheran, &c. The true definition of the visible church has been a matter of much controversy. The English church, in her 19th article, explains it to be "a congregation of faithful men, in which the pure word of God is preached, and the sacraments duly administered, according to Christ's ordinance, in all those things that of necessity are requisite to the same." What these necessary requisites are is not dogmatically laid down, whence many communities come to be comprehended in the visible church by English divines which the Romish and other authorities exclude. Many sects, however, extend the pale still further, not considering the reception of the sacraments as any test of churchmanship, but referring it solely to the earnest belief and moral conduct of individuals.

CHURCH. In Architecture, a building dedicated to the performance of Christian worship. Under the art. ARCHITECTURE an account is given of the Basilicæ which were first used for the assembly of the early Christians, to which the reader is referred. Among the first of the churches was that of St. Peter's at Rome, about the year 326, nearly on the site of the present church; and it is supposed that the first church of St. Sophia at Constantinople was built somewhat on its model. That which was afterwards erected by Justinian seems in its turn to have afforded the model of St. Mark's at Venice, which was the first in Italy constructed with pendentives and a dome, the former affording the means of covering a square plan with an hemispherical vault. The four most celebrated churches in Europe erected since the revival of the arts are, St. Peter's at Rome, which stands on an area of 227,069 feet superficial; Sta. Maria del Fiore at Florence, standing on 84,802 feet; St. Paul's, London, which stands on 84,025 feet; and St. Genevieve at Paris, 60,287 feet. The churches on the Continent are usually ranged under seven classes: *Pontifical*, as St. Peter's, where the pope occasionally officiates; *Patriarchal*, where the government is in a patriarch; *Metropolitan*, where an archbishop is the head; *Cathedral*, where a bishop presides; *Collegiate*, when attached to a college; *Parochial*, attached to a parish; and *Conventual*, when belonging to a convent.

CHU'SITE. (Gr. χυω, *I pour.*) A very fusible mineral found near Limbourg.

CHYA'ZIC ACID. From the initials of *carbon*, *hydrogen*, and *azote*. A term applied to the compounds of hydrocyanic acid.

CHYLE. (Gr. χυλος.) The nutritious fluid prepared from the chyme, and imbibed by the lacteals to be conveyed to the thoracic duct and venous system. It contains about 10 per cent. of solid matter. In most mammals it is white; in birds transparent, except in some that live on ants and insects, as the wood-pecker, which has been observed to be opake; it is white in the crocodile, but colourless and transparent in other reptiles and in fishes.

CHY'LOPOIE'TIC. (Gr. χυλος, and ποιεω, *I make.*) Organs concerned in the formation of chyle; hence the stomach, duodenum, and liver are termed chylopoietic viscera.

CHYME. (Gr. χυμος, *juice.*) The pulpy layer of nutritious digested matter which adheres to the inner surface of the intestine, and yields the chyle by admixture with the biliary secretion.

CIBO'RIUM. (Gr. κιβωριον.) In Architecture, an insulated erection open on each side, with arches, and having a dome of ogee form carried or supported by four columns. It is also used to denote the coffer or case which contains the Host.

CICA'DA. (Lat. *a grass-hopper.*) The name of a Linnæan genus of insects, celebrated in all ages for their powers of song or shrill chirp.

> Et cantu querulæ rumpent arbusta cicadæ,
> (*Georgics*, iii.)

sings Virgil; which Dryden renders,

> When creaking *grass-hoppers* on shrubs complain:

although it is evident that Virgil alluded to the insects of the present genus, which habitually frequent shrubs and trees, and feed on their juices, having a peculiar apparatus for piercing the bark and sucking out the juice. They are therefore more accurately described by Lord Byron, as

> The shrill Cicadæ, people of the pine.

The *manna* of the shops is the inspissated juice of the *Fraxinus ornus*, poured out from the wounds inflicted by the *Cicada orni*. The organ of sound is peculiar to the male, and is situated on each side of the under and anterior part of the abdomen. The insects referable to the Linnæan genus *Cicadæ* are now separated into three families — *Cicadidæ*, *Fulgeridæ*, and *Cercopidæ*.

CICA'TRIX. (Lat.) The scar which remains after the skinning over of a wound.

CICERO'NE. (Ital.) A name originally given by the Italians to those persons who pointed out to travellers the interesting objects with which Italy abounds; but applied universally at present to any individual who acts as *a guide*. This application of the term Cicerone has probably its origin in the ironical exclamation, "E un Cicerone" (he is a Cicero), being elicited from the traveller by the well-known garrulity of the Italian guides.

CICHORA'CEÆ. (Gr. κιχωρη, name of the herb *Cichory.*) One of the four divisions of *Compositæ*, a very extensive order of herbaceous or shrubby Exogens. The plants belonging to this division have a milky juice, and form a connecting link between *Compositæ* and *Campanulaceæ*. They inhabit the whole world, and are characterized by all the florets of the flower-heads being alike and ligulate. Lettuce, succory, and endive are familiar examples of *Cichoraceæ*, which are generally bitter, with a soporific quality resembling that of opium.

CICI'NDELA. (Lat. cicendela, *a glow-worm.*) A name applied by Linnæus to a genus of beetles, which is placed at the head of the order *Coleoptera*, from the circumstance of the outer lobe of the maxillæ being converted into an additional pair of feelers, called internal maxillary palpi. The mandibles are very strong, and armed with strong teeth; the maxillæ are terminated by a moveable spur; the eyes are large and prominent; and the wings generally well developed. Endowed with such powers of perception, locomotion, and destruction, it may be readily inferred that these insects are a cruel and predatory race. Like the carnivora of a higher class, they are remarkable for the beauty of their colours, and were termed by Linnæus the tigers of the insect world. The species referable to the Linnæan *Cicindela* are extremely numerous, and are divided into twenty subgenera; of which one only is British, and to this the term *Cicindela* is restricted.

CICISBE'O. (Ital.) A word synonymous with *cavalier servente*, and applied to a class of persons in Italy who attend on married ladies with all the respect and devotion of lovers. Formerly the establishment of a fashionable lady was not considered complete without a cicisbeo, whose duty it was to accompany her to private parties and public amusements, to escort her in her walks, and in short to be always at her side ready for her commands. This practice is now, however, on the decline. Though

the office of a cicisbeo has been the subject of frequent invective, it has not been without its advocates and admirers. Among others, Baretti has taken great pains to vindicate this custom in his *Account of the Manners, &c. of Italy*, vol. i. c. 8. He ascribes it to a spirit of gallantry derived from the ages of chivalry, and much heightened and refined by the revival of the Platonic philosophy in Italy about the 13th century, and by the verses of Petrarch and his numerous imitators.

CICO'NIA. (Lat. *a stork.*) A genus of wading birds of the tribe *Cultrirostres* of Cuvier; including the white stork (*Ciconia alba*), the black stork (*Ciconia nigra*), and the American stork (*Ciconia magnari*).

CID. (Arab. seid, *lord.*) The name given to an epic poem of the Spaniards which celebrates the exploits of their national hero, Roderigo Diaz, Count of Bivar. It is supposed to have been written in the 13th century, about 150 years after the hero's death; but unfortunately the author's name has not been transmitted to posterity. (See *Southey's Chronicle of the Cid.*)

CI'DER. A fermented liquor made from the juice of apples. Cider is made in all the temperate climates of the world which are not sufficiently warm for maturing the grape, and where the cold is not so great as to reduce the inhabitants to only the beer produced by a fermented decoction of grain. Cider is formed by grinding or crushing the apples when ripe, either in a circular stone trough by a stone roller turned by a horse (which is the common practice in Worcestershire, Herefordshire, &c.), or between fluted or spiky, and afterwards between smooth rollers of wood or iron, driven by men (as practised in Devonshire, and in most places where cider is made on a small scale). The apples, including the core and the seeds, being reduced to a pulp by crushing or grinding, the mass is put into a haircloth and powerfully pressed; and the liquor which runs from it is put into casks, where it is allowed to ferment, the casks being freely exposed to the air in the shade; the progress of the fermentation is then carefully watched, and as the sediment has subsided the liquor is racked off; on the proper time being chosen for doing this depends the excellence of the cider. The best cider, other circumstances being the same, is that in which the fermentation has gone on slowly, and where the vinous fermentation has not gone so far as to become acetous. The check to fermentation consists in racking off from one cask to another. Before winter the casks are removed to a cellar, and by the following spring the liquor is fit for use, or for bottling. The principal cider counties in England are Worcestershire, Herefordshire, and Devonshire. The Worcestershire and Herefordshire cider will keep from twenty to thirty years; while the best Devonshire cider will rarely keep more than five or six years.

CI'LIA. (Lat. cilium, *an eyelash.*) The hairs which grow from the margin of the eyelids; the term is also applied to microscopic filaments or plates which project from animal membranes and are endowed with quick vibratile motion. In most of the lower animals the respiratory function is effected by means of the vibratile cilia; many animalcules and the gemmules of the Acrites move by a similar mechanism; and it has recently been ascertained that vibratile cilia have a share in the performance of some important functions in the highest classes of the animal kingdom, where they have been detected on the membrane lining the female generative and respiratory passages, and the ventricles of the brain.

Cilia. In Botany, long hairs situated upon the margin of a vegetable body, as on the leaves of the *Sempervivum tectorum.*

CI'LIARY. (Lat. cilium.) The *ciliary ligament* of the eye is the circular portion that divides the choroid membrane from the iris, and which adheres to the sclerotic coat. The *ciliary processes* are the white folds at the margin of the *uvea* in the eye, which proceed from it to the crystalline lens.

CI'LIATED. (Lat. cilium.) A term used in describing the surface of an organ, to denote the presence at the margin of fine hairs resembling the eyelash, as in the leaves of *Luzula pilosa.*

CI'LIOGRADE, *Ciliograda.* (Lat. cilium and gradior, *I proceed.*) The name of a tribe of Acalephans or sea-nettles, comprehending those which swim by means of cilia.

CI'MEX. (Lat. cimex, *a bug.*) A Linnæan genus of Hemipterous insects, now subdivided into the following families,—*Pentatomidæ, Coroidæ, Lygoidæ, Cypridæ, Cimicidæ, Reduviidæ, Acanthidæ, Hydrometridæ.* Each of these families includes several genera, and each genus comprises many species; in all the mouth consists of one lengthened and jointed proboscis, including several fine sharp bristle-like processes, which are employed in wounding the vegetable or animal substances on the juices of which these insects feed. The bed-bug (*Cimex lectularius*) may be regarded as a type of this extensive tribe of insects.

CI'MOLITE. A mineral found in the island of Cimola in amorphous earthy masses: it is a hydrated silicate of alumina.

CINCHO'NA. The generic name of certain trees yielding a bitter febrifuge bark, the virtues of which are to be ascribed to the presence of the vegetable alkaloids called *cinchonia* and *quinia.*

Three species of cinchona bark are directed in the London Pharmacopœia to be kept for medical use; namely, the *pale, yellow,* and *red barks.* The first of these is furnished by *C. condaminea,* and contains cinchonia; the second, yielded by *C. lanceolata,* produces quinia; and the third, whose origin is not ascertained, possesses a mixture of the two.

CINCHONA'CEÆ. (Cinchona, one of the genera.) A natural order of shrubby or arborescent Exogens, almost exclusively inhabiting the tropics and the hotter parts of the world. They are in some respects allied to *Compositæ,* from which their distinct stamens, bilocular or plurilocular ovary, and inflorescence distinguish them. They are divided from *Apocynaceæ* by the æstivation of the corolla, the presence of stipules, and the inferior ovary; although, according to Brown, there exists a genus in equinoctial Africa which has the interpetiolary stipules and seeds of *Cinchonaceæ,* and the superior ovary of *Apocynaceæ,* thus connecting the two orders. They are most nearly related to *Caprifoliaceæ,* being only separated from them by their interpetiolary stipules. Brown describes a tribe called *Opercularineæ* as having but one seed, and the number of stamens unequal to the lobes of the corolla; thus occupying, as it would seem, an intermediate position between *Cinchonaceæ* and *Dipsaceæ.* Powerful febrifugal properties in their bark or emetic in the roots are the great features of this order, the most efficient products of which are *cinchona* and *ipecacuanha.* Many of the plants of the order are fragrant and of great beauty; but, with the exception of the *Gardenea, Lucula,* and a few others, the handsome kinds are hardly known to cultivators.

CI'NCTURE. (Lat. cingo, *I surround.*) In Architecture, the ring, list, or fillet at the top and bottom of a column, which divides the shaft of the column from its capital and base.

CINE'REOUS. (Lat. cinis, *ashes.*) Grey; the colour of wood-ashes.

CI'NGULUM. (Lat. cingulum, *a girdle.*) In Zoology, is technically applied to the neck of a tooth, or to that more or less distinct constriction which separates the crown from the fang. The term *cingula* is also given to the transverse series of bony pieces connected together by tegumentary flexile joints, as in the middle part of the armour of the armadillo.

CI'NNABAR. An Indian name, given, according to Pliny, to a mixture of the blood of the dragon and elephant, and other substances of similar colour. It is now exclusively applied to the red pigment called *vermilion.* It is a *bisulphuret of mercury,* composed of 200 mercury + 32 sulphur.

CI'NNAMON. The bark of the *Cinnamomum zeylanicum.* This tree is a native of Ceylon, whence the finest cinnamon is obtained; it is of an astringent and highly aromatic and warm flavour, and yields by distillation an extremely fragrant and pungent volatile oil, kept for pharmaceutical use under the name of *oil of cinnamon.* An inferior kind of cinnamon is often met with in commerce, which is remarkably deficient in flavour.

CI'NNAMON STONE. (So called from its colour.) A silicate of lime, alumine, and oxide of iron, from Ceylon. It occurs massive and in rounded pieces in the sand of rivers; some of these are occasionally cut and polished for jewellery.

CINQUE PORTS, or FIVE PORTS. The seaport towns of Dover, Sandwich, Hastings, Hithe, and Romney; to which three others were afterwards added, viz. Winchilsea, Rye, and Seaford. These towns are incorporated, with peculiar privileges; are under the government of a lord warden, to whom writs for the return of members to parliament from them are directed; and the members so returned are termed Barons of the Cinque Ports.

CI'PHER. (Heb. saphar, *to number.*) The character 0 in numeral notation, which, standing by itself, signifies *nothing,* or the privation of value. When combined with other numeral characters, its use is to determine their position with regard to the unit's place, and consequently the power of ten, by which their absolute values must be severally multiplied to produce the number they are intended to represent.

Cipher is sometimes used in common language to signify any arithmetical character; hence the verb *to cipher,* which signifies to perform an arithmetical operation. This term, which is found in all European languages, was no doubt introduced into Spain by the Saracens, along with the Arabic figures, which appear to have come into use among astronomers in the thirteenth or early in the fourteenth century (for the time of their first introduction is not certainly known), and to have been gradually circulated over Europe in the almanacs.

CI'POLIN. A green marble with white zones, somewhat like the section of an onion.

CI'RCINNATE. (Lat. circino, *I make a circle.*) A term used in describing the æstivation of flowers, and the direction of plants in general, to denote those which are rolled spirally downwards, so that they are bent like the head of a crosier; as the shoots of young ferns, the inflorescence of Boraginaceous plants, the leaves of the Sundew.

CI'RCLE. (Lat. circulus.) In Geometry, a plane figure contained by one line, which is called the circumference, and such that all straight lines drawn from a certain point within the figure to the circumference are equal to one another. The point which possesses this property is called the centre of the circle. The straight line and the circle are the only figures admitted into plane or elementary geometry, all questions in that branch of mathematics depending on the intersections of straight lines with straight lines, of straight lines with circles, or of circles with circles. This distinction was established by the ancient geometricians, who regarded the other geometrical figures as formed by the intersections of planes with solids, and thence denominated problems, for the solution of which the properties of other figures than the straight line and the circle were required,—*solid problems.* The algebraic analysis points to a different distinction. An equation between two indeterminate quantities, neither of which rises above the first degree, represents a straight line. When either or both of the interminate quantities rise to the second degree, the equation may represent a circle, an ellipse, an hyperbola, or a parabola. The circle thus belongs to the same class of curve lines as those which have been termed conic sections; and in fact a cone may be cut by a plane so that the section shall be a circle, as well as any one of the other three curves.

The circle derives its chief importance from its application to trigonometry, or the measurement of angles. Instead of directly comparing angles with one another, it is more convenient to compare the arcs (described with the same radius) contained between the sides of the angle. The numerical relations of different angles, or the corresponding arcs, are expressed as follows:—The circle is divided into four equal parts, and the four portions of the circumference thus formed serve as the measure of four right angles, which comprehend the whole space about the centre. Each of these *quarters* of the circumference is divided into 90 equal parts, called *degrees.* The whole circumference, therefore, contains four times 90, or 360 degrees. This division, adopted in the most ancient times, appears sufficiently capricious; nevertheless it is very convenient, inasmuch as the number 360 contains many primes, and consequently permits many subdivisions into parts expressible by whole numbers. Thus, the half contains 180 degrees; the third, 120; the fourth, 90; the fifth, 72; the sixth, 60; the eighth, 45; the tenth, 36; the twelfth, 30; the fifteenth, 24, &c. In order to measure smaller parts of an angle than a degree, the degree is subdivided into 60 minutes or *primes*, and the minute into 60 seconds. Since the decimal arithmetic came into general use, the sexagesimal division is not carried farther than seconds in expressing angular magnitude, the parts of a second being now always represented by decimals. The whole circumference of the circle contains 21,600 minutes or 1,296,000 seconds.

The rectification of the circle, or the determination of the ratio of the circumference to the diameter, is a problem which has exercised the ingenuity of mathematicians in all ages. It cannot be expressed in finite numbers; but numerous series have been invented from which it may be computed to any required degree of precision. Archimedes, in his treatise *De Dimensione Circuli*, proved that if the diameter is expressed by 7, the circumference is very nearly 22. A nearer ratio, which is generally used in ordinary measurements, is 113 to 355; and it has the advantage of being easily remembered, the numbers being formed of the three first odd numbers, each repeated. Vieta carried the approximation to 10 places of figures, and Van Ceulen to 36. Mr. Abraham Sharp computed the ratio to 72 places of figures; and finally De Lagny, in the *Memoirs of the Academy of Sciences of Paris*, extended it to 128; an example of patient industry without a use. Supposing the diameter 1, the first thirty-six figures by which the circumference is expressed (or the ratio found by Van Ceulen) are

3·14159,26535,89793,23846,26433,83279,50288.

Of the series by which the circumference is expressed in terms of the diameter, one of the simplest is

$$c = 4 \times \left(1 - \tfrac{1}{3} + \tfrac{1}{5} - \tfrac{1}{7} + \tfrac{1}{9} - \tfrac{1}{11} + \tfrac{1}{13} - \tfrac{1}{15} +, \&c.\right);$$

but the following is better adapted for calculation,

$$c = 4 \times \left(1 - \frac{\cdot 1}{2 \cdot 3} - \frac{1}{2 \cdot 4 \cdot 5} - \frac{1 \cdot 3}{2 \cdot 4 \cdot 6 \cdot 7} - \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6 \cdot 8 \cdot 9}, \&c.\right)$$

The areas of circles, as of plane similar figures, are to one another in the ratio of the squares of their diameters. If the diameter is unit, the area is one fourth of the circumference, and is expressed by the decimal ·7853981633974483, &c. to sixteen places. This is nearly in the proportion of 14 to 11, which was the approximation given by Archimedes. Some of the series by which the ratio of the area of a circle to the square of its diameter is expressed are curious. The following was given by Dr. Wallis in his *Arithmetic of Infinities:*—

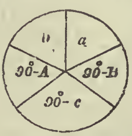
$$\frac{2 \times 4 \times 4 \times 6 \times 6 \times 8 \times, \&c.}{3 \times 3 \times 5 \times 5 \times 7 \times 7 \times, \&c.}$$

This is the same as $\frac{8}{9} \times \frac{24}{25} \times \frac{48}{49} \times$, &c., the denominators being the squares of the odd numbers, and the numerators differing from the denominators by unity. Since the invention of the infinitesimal calculus the discovery of series for the rectification and quadrature of the circle is a matter of comparative facility. A number of them may be seen in *Euler's Introductio in Analysin Infinitorum.*

CI'RCUITS. (Lat. circumeo, *I go round.*) In England, Scotland, and Ireland, divisions of the kingdom appointed for the judges of assize; two of whom go each circuit twice a year, to deliver the gaols and try issues at nisi prius. England is divided into six circuits—Home, Midland, Oxford, Norfolk, Western, Northern; Wales into the North and South Welsh circuits. A single judge travels each of the Welsh circuits, and these two meet at Chester to transact the business of that county. The judges choose their own circuits; the three chiefs, and the puisne judges, in order of seniority, making their election. The circuits are after Hilary and Trinity Terms, and vary in their duration from three to seven or eight weeks. (*See* COURTS, SUPERIOR; and ASSIZE.) The circuit or assize towns in most counties have been fixed by immemorial usage, but some changes have recently been made by the authority of the privy council. Barristers at the common law bar choose their circuits on first embarking in their profession, and etiquette allows of only one subsequent change. The insolvent commissioners also make circuits thrice a year through the kingdom for the discharge of debtors.

CI'RCULAR INSTRUMENTS. The name given to any astronomical or nautical instrument for measuring angles, in which the graduation extends round the whole circumference, or to 360°. Formerly it was thought sufficient to carry the divisions over a portion of a circle only, whence the quadrants, sextants, and octants, once so common; but experience has shown that entire circles (especially where the instruments are of considerable size) have a great advantage over graduated segments; and hence, excepting the sea-sextant, the latter are now seldom used. The principal circular instruments used in astronomy are *altitude* and *azimuth circles*, *mural circles*, *reflecting circles*, and *repeating circles.* The altitude and azimuth circle, as its name implies, is used for measuring the altitudes and azimuths of stars; it is consequently composed of two graduated circles, one vertical and the other horizontal. This is a sort of universal instrument, being applicable to almost all the purposes of astronomy. The *mural circle* is so called because it is supported by means of a long axis passing into a *wall*, the plane of the circle being parallel to the wall. The instrument is placed in the meridian, and is used for determining the polar or zenith distances of celestial objects. (*See* MURAL CIRCLE.) The *reflecting circle* carries a mirror, by means of which an object is seen by reflected vision; another object is viewed directly; the two are brought to coincide, and the angular distance between them is measured by the inclination of the mirror to the axis of the telescope. (*See* SEXTANT.) The *repeating circle*, or *multiplying circle*, is so contrived that the observer is enabled to repeat or multiply the observation, by reading it off successively on different parts of the graduated limb. A number of values being thus found, the mean of the whole is taken as the correct result. This instrument is sometimes called Borda's circle, from the name of its improver. *See* REPEATING CIRCLE.

CI'RCULAR PARTS. In Trigonometry, the name given to a proposition invented by Lord Napier, and demonstrated in his *Mirifici Logarithmorum Canonis Descriptio*, which gives all the relations between the parts of a right-angled spherical triangle in two formulæ. It is this:—In any right-angled spherical triangle, let *a* and *b* denote the sides, *c* the hypothenuse, and A and B the angles opposite to *a* and *b* respectively. Take the two sides, and the complements of the hypothenuse and of the two angles, and write them in order round a circle, as in the annexed diagram; then, if any one part be called the *middle* part, the two next to it are the *adjacent* parts, and the other two the *opposite* parts; and the two following rules will hold good:—



1. The sine of the *middle* part is equal to the product of the tangents of the *adjacent* parts. 2. The sine of the middle part is equal to the product of the cosines of the *opposite* parts. Thus,

$$\text{Sin. } a = \tan. b, \tan. (90 - B).$$
$$\text{Sin. } a = \cos. (90^\circ - A) \cos. (90^\circ - c).$$

CI'RCULATING DECIMALS. Are decimals in which two or more figures are constantly repeated in the same order; thus, 09, 09,09, &c.; 234,234,234, &c.; ·142587, ·142857, 1, &c. A decimal of this sort is equal to a vulgar fraction of which the numerator is the *period* or circulating figures, and the denominator as may *nines* as there are figures in the numerator.

CIRCUMCI'SION. The initiatory rite of the Jewish covenant; which, as is recorded, was first enjoined to Abraham by God, and after his posterity had neglected it during their wanderings through the desert, was solemnly renewed upon the passage of the Jordan. (Josh. v. 1—10.)

This custom of cutting off the foreskin has been long prevalent among Eastern nations. Herodotus refers to it as the practice of the Egyptians and Ethiopians, and as borrowed from them by the Phœnicians and Syrians. It does not appear, however, to have been considered by these nations in the light of a religious ceremony. It is enforced by the Koran upon all the disciples of Mahomet, whether from an idea of salubrity vulgarly attributed to it in the East, or merely as a distinguishing rite.

CIRCU'MFERENTOR. An instrument used by surveyors for taking angles. It consists of a graduated brass circle and an index all of one piece, and carrying a magnetic needle suspended above the centre of the circle. The index being directed to an object, the angle which it makes with the magnetic meridian is noted. The index is then directed to the second object, and the angle it makes with the same meridian observed in like manner. The difference (or sum, as the case may be) of the two observed angles gives the angle between the two objects. It is evident that only a very rough approximation can be obtained in this manner. For the purposes of surveying, a pocket sextant is a far preferable instrument.

CI'RCUMFLE'XUS A muscle of the palate: the term is also applied to arteries which wind round bones or joints.

CI'RCUMPO'LAR STARS. Are those stars which at any given place move round the pole, or complete their diurnal circles, without setting. The number of stars so circumstanced increases with the latitude of the place or the elevation of the pole above the horizon.

CIR'CUMSCI'SSILE. (Lat. circumscindo, *I cut round.*) A mode of dehiscence observed in the fruit of some plants; it occurs by a transverse circular separation of the sides of the ovary, as in *Anagallis*, *Hyoscyamus*, and is analogous to the transverse articulations found in the leaf of the orange or the pod of ornithopus.

CI'RCUMSCRI'PTION. (Lat. circumscriptio, *a boundary.*) The line representing the two edges of a leaf, *i. e.* its margin; it is also used to denote the figure represented by the margin of any other body.

CI'RCUMVALLA'TION. (Lat. circum, *about*, and vallum, *a rampart.*) In Fortification, a trench or bulwark thrown up about a camp or besieged city, composed of the earth dug up from the ditch and of sharp stakes planted in it.

CI'RCUS. A straight long narrow building, whose length to its breadth was generally as five to one. It was divided down the centre by an ornamented barrier called the spina, and was used by the Romans for the exhibition of public spectacles and chariot races. There were several of these at Rome, of which the most celebrated was the Circus Maximus.

Julius Cæsar improved and altered the Circus Maximus; and that it might serve for the purpose of a naumachia, supplied it with water. Augustus added to it the celebrated obelisk now standing in the Piazza del Popolo. No vestiges of this circus remain. Besides these were at Rome the Circi of Flaminius, near the Pantheon; Agonalis, occupying the site of what is now the Piazza Navona; of Nero, on a portion whereof St. Peter's stands; Florus, Antoninus, and Aurelian, no longer even in ruins; and that of Caracalla, which was 738 feet in length, and is sufficiently perfect in the present day to exhibit its plan and distribution in the most satisfactory manner.

The spectacles exhibited in the circus were called the Circensian Games, and consisted chiefly of chariot and horse races. The Romans were passionately fond of them, and more particularly of the chariot races, which excited so great an interest in the times of the emperors as to divide the whole population of the city into factions, known by the names of the colours worn by the different charioteers. The disputes of these factions sometimes led to serious disturbances, and even bloodshed.

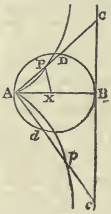
CI'RRHOUS. (Lat. cirrus, *a tendril.*) A term used in describing the apices of bodies, to indicate those that are terminated by a spiral or flexuose filiform appendage, arising from an elongation of the costa, as in the leaf of *Gloriosa lupercha.* It is also applied to modifications of branches, inflorescence, the petiole, &c. when such parts assume the state of a twisting body, which enables the plant belonging to it to raise itself upon neighbouring objects.

CI'RRIPEDS, *Cirripedia.* (Lat. cirrus, and pes, *a foot; curly-footed.*) A class of fixed homogangliate animals, characterized by having a number of long, curled, articulated, setigerous processes, analogous to the feet of the Crustaceans, which project from the central aperture of the multivalve shell protecting the body. These animals are commonly called barnacles and acorn-shells. *See* LEPADITES and BALANITES.

CI'RROUS. Furnished with tendril-like appendages.

CI'RSOCE'LE. (Gr. *κιρσος, a dilated vein,* and *κηλη, a tumour.*) A morbid enlargement of the spermatic veins in the groin.

CI'SSOID. In Geometry, a curve line of the second order, invented by Diocles, with a view to the solution of the famous problem of the *duplication of the cube*, or the insertion of two mean proportionals between two given straight lines. Its name is derived from *κισσος, ivy;* because the curve appears to mount along its asymptote as ivy climbs on the tall trunk of a tree. The curve is described as follows:—



From A, one of the extremities of the diameter of a circle, draw a straight line, A C (or a c), to meet the tangent through the other extremity, and make C P equal to the intercepted chord A D; the point P will trace the cissoid. The line A C may be conceived to turn on both sides of the diameter A B till it falls into the position of a tangent to the circle at A. The curve, therefore, consists of two infinite branches, which approach always nearer to the tangent C B c without ever meeting it, whence this line is an asymptote to the cissoid. The point A being taken for the origin of the co-ordinates, and the diameter A B as the axis of the abscissa, the equation of the curve is $x^3 = (a-x)\, y^2$, a being the diameter of the generating circle. One of the most remarkable properties of the cissoid is, that the whole space lying between the double branches and the asymptote is equal to triple the area of the generating circle. A method of describing the cissoid mechanically by the motion of a rectangular rule, is given in *Newton's Universal Arithmetic.*

CIST. (Gr. *κίστη, a chest.*) In Architecture and Sculpture, a chest or basket. It is a term usually applied to the mystic baskets employed in processions connected with the Eleusinian mysteries. They were originally of wicker work, and when afterwards made of metal the form and texture were preserved in imitation of the original material. When sculptured on antique monuments it indicates some connection with the mysteries of Ceres and Bacchus.

CISTA'CEÆ. (Cistus, one of the genera.) A natural order of shrubby or herbaceous Exogens inhabiting chiefly the countries of the south of Europe and North America. They are distinguished from *Violaceæ* by their indefinite stamens and inverted embryo; from *Bixaceæ* by the last character, by their mealy albumen, habit, and not having the leaves ever dotted; from *Hypericaceæ* by the latter character, and the structure of the fruit. They are allied to *Papaveraceæ* by the genus *Dendromecon;* but their true station appears to be in the vicinity of *Linaceæ*, to which they approach by the genus *Lechea.* They are often plants of great beauty, but possess no sensible properties, excepting the *Cistus creticus* and a few others, which yield the resinous balsamic substance called gum labdanum.

CI'STERN. (Lat. cisterna, from Gr. *κίστη.*) In Architecture, a reservoir or receptacle of water for public or domestic use. When made of brick or stone it is commonly called a tank.

CI'STVAEN. A species of stone receptacle, often found in barrows (generally at the east end), containing the bones of the persons interred there. Cistvaens are commonly three stones placed on edge, like the three sides of a box, with a stone cover. Some which are styled cistvaens by Sir R. Hoare and other antiquaries are, however, not sepulchral.

CITA'TION. (Lat. cito, *I call.*) In Ecclesiastical Law, an act whereby the defendant, on the application of the plaintiff, is commanded to appear in court on a certain day in order to enter into a suit. In the Civil Law, reference to an authority or precedent in the course of a pleading is termed a citation; and hence the common use of the word in the same sense with quotation, allegation of instances, &c.

CI'TRATES. The salts of citric acid.

CITRE'NE. A crystalline compound of hydrogen and carbon, obtained from the essential oil of lemons.

CI'TRIC ACID. (Lat. citrus, *the lemon.*) The pure

acid part of lemon and lime juice; it is also found in other fruits. Crystallized citric acid is largely prepared for domestic use.

CI'TY. (Lat. civitas.) A borough or town corporate, which is or has been the seat of a bishop, or the capital of his see; and it differs in no respect but that of superior dignity from another borough. Some cities and a few boroughs are counties in themselves

CI'VET. A brown semifluid matter contained in a gland near the anus of the *Viverra civetta* or *civet cat:* its odour is offensive unless extremely diluted, and then in combination with other perfumes it adds to their energy.

CI'VIL ARCHITECTURE. *See* ARCHITECTURE.

CIVI'LIAN. One learned in the Civil or Roman Law; particularly a member of the "College of Doctors of Law exercent in the Ecclesiastical and Admiralty Courts" in England and Wales, in which courts the civil law is recognized. (*See* LAW, CIVIL.) Practice as an advocate in those courts is confined to members of this college, who must have taken the degree of Doctor of Law in the university of Oxford or Cambridge.

CI'VIL LIST. The term formerly applied to the list of all the expenses of the government, or "of all the heads of public expenditure, excepting those of the army, the navy, and the other military departments;" but confined at present by the act 1 W. 4. c. 25. to expenses proper for the maintenance of her majesty's household. In England the civil list is fixed in the first session of parliament after the accession of the sovereign, and is then understood to be granted for the whole period of his reign.

CLAMP. (From the French.) In Architecture, a piece of wood fixed to another with a mortise and tenon, or a groove and tongue, so that the fibres of the piece thus fixed cross those of the other, and thereby prevent it from casting or warping.

CLAMP. In Brickmaking, a large mass of bricks, generally quadrangular on the plan, and 6, 7, or 8 feet high, arranged in the brick field for burning, which is effected by flues prepared in stacking the clamp, and breeze or cinders layed between each course of bricks.

CLAN. (Said to be derived from the Gaelic clann, *descendants or issue.*) The clans of the Scottish Highlands are tribes consisting of many families all bearing the same surname, which according to tradition descend from a common ancestor. But it is more probable that most clans were formed of an aggregate of different families, the inferior standing to the superior in the same sort of relation as the Roman clients to their patrons, and by degrees assuming the same name. Some clans, however, are divided into branches, each possessing a distinct surname. The chieftainship of every clan descends regularly through heirs male; but in the earliest times of their history the rights of primogeniture were not very distinctly defined. The Gaelic clans occupy the northern and western with part of the central shires of the country. A Gaelic manuscript lately discovered containing genealogies of the Highland clans, and supposed to have been written about the year 1440, should seem to carry back the antiquity of the singular institution of clanship even to a remoter period than was previously believed.

CLA'RET. This term is applied to several of the Bourdeaux wines; it is derived from the Latin claretum, from clarere, *to be clear. See* WINE.

CLA'RINET. (It. clarino.) A wooden musical wind instrument, whose mouth partakes of the trumpet form, and is played by holes and keys: said to have been invented about the year 1600 by John Christopher Denner of Leipsic. Like the oboe it is played with a reed mouthpiece, though it is of somewhat different form.

CLA'SSES. In Ancient History, this term is particularly applied to the division of the Roman people made by Servius Tullius for the purpose of distributing them into centuries. *See* CENTURIES.

CLA'SSIC. (Lat. classis, *a class.*) In the Fine Arts, a term denoting such an arrangement of a subject that all the accessories or parts are suitable to the general design, and such that nothing be introduced which does not strictly belong to the particular class under which it is placed.

CLASSIC. In Antiquity, the Roman people were divided into classes, and the highest order were by pre-eminence termed *classici.* Hence the name came to signify the highest and purest class of writers in any language; although, down to a comparatively recent period, the term was used merely to denote the most esteemed Greek and Latin authors. Nothing marks more strongly the increased attention to, and appreciation of, modern literature, than the now universal application of the term to modern languages also, and the establishment in this manner of a line between those authors whom we regard as models and authorities in point of style, and those who are not so highly esteemed. An author is said to be *classical* if public opinion has placed him in the former order: language, or an expression, to be *classical,* if it be such as has been used in a similar sense and under similar rules of construction by those authors. The epithet classical, as applied to ancient authors, is determined less by the purity of their style than by the period at which they wrote. Thus we speak of the classical age of Greek or Latin writing. With respect to the former, the classical age begins with Homer, the earliest Greek writer with whom we are acquainted. The purest age of Greek classical literature may be said to end about the time of the Macedonian conquest, or about 300 B.C.; but, in a wider sense, it extends to the time of the Antonines, and embraces a much larger catalogue of authors; while the centuries subsequent to that time produced a few, who by the purity of their style deserve to be ranked with earlier classics. The Latin classical period is shorter: its earliest writer is Plautus, and the language may be said to have lost its classical character about the same time with the Greek, *i.e.* the reigns of the Antonines; although this limit is arbitrary, and some later writers (even down to Claudian) are generally included among classics. Within the Latin classical era there is a more restricted period of the purest Latinity, comprising the age of Cicero and that of Augustus.

CLA'SSIFICA'TION. (Lat. classis, *a class.*) In the Fine Arts, an arrangement by which objects of the fine arts are distributed in classes; as, for instance, in galleries of paintings, the works should be arranged in schools, each school being subject to a chronological order of the masters. In Numismatology, the coins should be arranged by countries, and these again in chronological order of the monarchs; and the like of other branches of the arts.

CLASSIFICATION, in Natural History, denotes the arrangement or assortment of various objects into those several classes denoted by appellatives which are called genera and species. For classification in Botany, Zoology, Medicine, Chemistry, &c., see the separate articles.

CLAU'SA. (Lat. clausus, *shut.*) A name given by Cuvier to a family of Acephalous bivalves, comprehending those which have the mantle open at one end, or near the middle, for the passage of the foot, and prolonged at the opposite end into a double tube for respiration and excretion.

CLAUSI'LIA. (Lat. clausus.) A genus of land-snails, so named because the aperture of the shell is closed internally by a spiral lid. Many species of this genus are natives of Great Britain. The rugose or dark close-shell (*Clausilia rugosa,* Drap.) is not uncommon at Charlton, where it may be found under stones. *Clausilia biplicata,* Leach, is found at Battersea.

CLA'VATE. (Lat. clava, *a club.*) Club-shaped; as when a body is linear at the base, but towards the apex growing gradually broader.

CLA'VICLE. (Lat. clavicula, from clavis, *a key.*) The bone situated between the sternum or breast-bone and the acromion process of the scapula or blade-bone. The megatherium is the largest mammal which possesses this bone.

CLA'VUS. (Lat. clavus, *a nail.*) In Agriculture, an excrescence from the grains of rye, of a brown or blackish colour. It is a parasitical fungus, called *Spermoedia clavus,* and is a valuable agent in exciting uterine action during labour. A severe pain in the forehead compared to the driving of a nail into the skull has been called *clavus* by medical writers.

CLAW, or UNGUIS. The narrow part at the base of a petal which takes the place of the footstalk of a leaf, of which it is a modification.

CLAY. In Chemistry, a term generally applied to a variety of *plastic* earthy compounds of different colours, and having much attraction for water. They are essential in the manufacture of pottery, and consist of silica, with variable quantities of alumina, and generally some oxide of iron.

CLAY. In Agriculture, one of the most common ingredients that enter into the composition of soils. Indeed, it may be asserted that no soil whatever will maintain its fertility for any length of time without a due proportion of clay in its composition. The most fertile soils in the world are the alluvial deposits on the banks of rivers; and these, in an agricultural sense, all belong to clayey soil. In many cases the clays of agriculture are intimately united with calcareous earths, and in others with sand; but in both cases these earths are in a state of such minute division, that the mixture has all the appearance and the mechanical properties of a strong clay, and they are treated by cultivators accordingly. Among the most tenacious clays of Britain are those of Middlesex; and these, when examined, are found in many cases to contain a considerable proportion of lime, and in others of sand. The best wheats are everywhere, both in Britain and on the Continent, grown on calcareous clays; and also the best fruits and flowers of the Rosaceous kind, such as apples, pears, plums, cherries, roses, &c.; but it is remarkable that the grape, when grown on clayey soil, produces neither high-flavoured fruit, nor good wine.

CLAYEY SOIL. Soil in which clay is the principal earthy ingredient. Soils of this description when first subjected to cultivation are expensive to labour, and uncertain in their produce; but after they have been drained, cultivated, limed, and manured for two or three generations, they become the most fertile of all soils, producing immense crops of wheat, beans, clover, rye-grass, &c.

CLEA'RING OF LAND. Removing such objects as impede the progress of the plough; such as stones, bushes, hillocks, and other obstructions.

CLEF. (Fr.) In Music, a mark prefixed to a staff, showing the tone or key in which a piece of music begins; or it is a letter or other sign marked on a line, which determines the name of all those of the degree whereon it is placed. A clef is always placed on a line, never on a space.

CLE'FT-GRAFTING. A mode of grafting, in which the scion is inserted in a cleft made in the stock. *See* GRAFTING.

CLEPSY'DRA. (Gr. κλεψύδρα, from κλέπτω, *I conceal*, and ὕδωρ, *water*.) Water clock; an ancient instrument for measuring time by the gradual emptying of a large vessel of water through an orifice of a determinate magnitude. Clepsydras were first brought into use in Egypt under the reign of the Ptolemys, and seem to have been common in Rome, though they were employed chiefly in winter; in summer sun-dials were used. Though clepsydras are attended with several inconveniences, the principal of which is the unequal rapidity of the flow caused either by a variation in the depth of the water in the containing vessel, or of temperature, or barometric pressure, they are nevertheless susceptible of considerable accuracy; and before the invention of clocks and watches, astronomers had no other dependence than on them for measuring small portions of time. At present they are abandoned, because pendulum clocks and watches are much more convenient, as well as infinitely more exact. In one case has the revival of their use been proposed; namely, for the accurate measurement of very small intervals of time by the flowing of mercury from a small orifice in the bottom of a vessel kept constantly filled to a fixed height. The stream is intercepted at the moment of noting any event, and diverted aside into a receiver, into which it continues to run till the moment of noting any other event, when the intercepting cause is suddenly removed. The stream then flows in its original course, and ceases to run into the receiver. The weight of mercury received, compared with the weight of that which passes through the orifice in a given time, observed by the clock, gives the interval between the events. This ingenious application of the principle of the clepsydra is due to the late Captain Kater.

CLE'RGY. The ecclesiastical body as distinguished from the laity. The word clergy seems to be derived from Gr. κλῆρος, *a lot or inheritance;* Lat. clerus, whence clericus, *a clerk or clergyman;* plur. clerici, whence *clergé, clergy;* and is supposed to allude to a custom, which, however, was never general, of choosing the clergy by lot; or, as St. Jerome says, to signify that the clergy are the lot and portion of the Lord, or the Lord is their lot. Perhaps the true derivation is rather to be traced from the lots (κλῆροι) by which the apostles chose Matthias to be one of their number. (Acts, 1. 26.)

Clerk (Lat. clericus) is still the legal appellation of a clergyman. The clergy being exclusively the learned part of the community in the middle ages, the word hence came to signify an educated person; and thus acquired the sense of a scribe or writer in France and England.

CLI'ENTS. (Lat. cliens, from the old word cluo, *I hear or obey*.) In Ancient History, a numerous body of the Roman citizens, so termed relatively to their patrons or protectors. This relation was in many respects similar to that of a serf to his feudal lord, but bore a much milder form. It was the duty of the patron to watch over the interests of his clients and protect them from aggression, and appear for them in lawsuits. He also frequently made them grants of land on lease. In return the client was bound to defend his patron, and contribute towards any extraordinary expences he might be subject to; as the portioning his daughters, the payment of a fine imposed by the state, &c. He might not appear as accuser or witness against him in judicial proceedings, a prohibition which was reciprocal. If he committed any offence against his patron, he was obliged to submit to him as his judge; and in ancient times it appears that the power of life and death was held by the latter. On the other hand, his security against oppression at the hands of his patron lay in the injunctions and authority of religion, which rendered the bond of union inviolably sacred, as that between father and son. The origin of this relation cannot now be traced; but it seems to have existed, with various modifications, throughout Italy and Greece. In Rome it appears at the foundation of the city by Romulus, when every family not included among the patricians was obliged to find itself a patron from their number. The body of clients was afterwards increased by the institution by which foreigners, who, as allies of Rome, had a share in its franchise, might choose themselves patrons on their coming to settle in the city. The obligations of clients were hereditary, and could not be shaken off unless through the decay of the family of the patron. This body alone in earlier times furnished artizans and shopkeepers; they had votes in the Comitia Centuriata; and though generally confounded with the plebeians, were undoubtedly perfectly distinct from them, as we continually meet in history with instances of their joining the patricians in opposition to the former; and when some of the plebeian houses became powerful, they themselves attached bodies of clients.

It has been seen that among the other duties of a Roman patron towards his client was that of maintaining his cause gratuitously in legal proceedings. Hence the term "client" has become appropriated in modern times to one whose cause is prosecuted or defended and his person represented by an advocate. The custom of practising gratuitously as advocates long prevailed among the Roman patricians; and from it the usage was derived, which still obtains among ourselves, of considering the fee of a counsel as "quiddam honorarium," a gratuity, which cannot be legally claimed. At present, the etiquette of the English bar appears to be this — that a barrister cannot refuse, without strong grounds for such refusal, to undertake any cause which is offered him; that he cannot refuse, without reasonable excuse, to plead gratuitously the cause of a client who sues regularly "in formâ pauperis;" or to defend a prisoner, if called on to do so by the court; and that he can receive no instructions with a fee except through the medium of a regularly authorized agent of his client (attorney or solicitor). An application to a barrister, with the customary fee, to undertake a cause in which he is not yet instructed, is called a "retainer," and secures his services for the client. An application to undertake all causes for a particular client is a *general* retainer.

CLIMACTE'RICAL YEAR. (Gr. κλιμακτὴρ, from κλῖμαξ, *ladder, scale.*) Certain years in the life of man have been from great antiquity supposed to have a peculiar importance, and to be liable to singular vicissitudes in his health and fortunes. This superstitious belief is said to have originated in the doctrines of Pythagoras. The well-known notice of the climacterical year sixty-three, supposed to be particularly dangerous to old men, in a letter of Augustus Cæsar preserved by Aulus Gellius, evinces its prevalence among the Romans. This year has been called by some astrological writers "heroicus," as having been peculiarly fatal to great men. The virtue of this year seems to consist in its being a multiple of the two mystical numbers, seven and nine. It is certainly singular that usage should have attached in all countries peculiar distinctions to those years which are denoted by compounds of the number seven. Thus fourteen has been fixed for various purposes as the epoch of puberty, twenty-one of full age; thirty-five is selected by Aristotle as the period when the body is in its highest physical vigour. The same author supposes the vigour of the mind to be perfected at forty-nine: sixty-three is the grand climacterical year; seventy the limit of the ordinary age of man. Bodinus says that seven is the climacterical number in men and six in women. The term *climacteric disease* has more lately been applied to that declension of bodily and vital powers which is frequently observed to come on in the latter period of life, and from which many persons again rally so as to attain extreme old age.

CLI'MATE. (Gr. κλίμα, from κλίνω, *I incline.*) Among the ancient geographers, was applied to denote that obliquity of the sphere with respect to the horizon which gives rise to the inequality of day and night. They divided the space comprehended between the equator and the pole into thirty parts, which they denominated *Climates* or *Inclinations;* viz. twenty-four between the equator and polar circle, and six between the polar circle and the pole. The first are called *half-hour* climates, because from one to another the longest day receives an augmentation of half an hour; the second are called *month* climates, because at the two parallels between which any one of them is comprehended the difference of the time of perpetual sunshine is one month. The first half-hour climate reaches from the equator to that parallel of latitude where the length of the longest day is twelve hours and a half; the second ends at the parallel where the longest day is thirteen hours, and so on. If, therefore, from the number of hours in the longest day at any particular place we subtract twelve, the number of half hours remaining will indicate the climate in which that place is situated. Thus, the longest day at London being a little more than sixteen hours and a half, London is situated in the tenth climate.

The first month climate extends from the polar circle to the parallel under which the sun continues above the horizon during a month; the second reaches from the

first to the parallel where the sun continues visible during two months; and so on to the poles, at which the sun is alternately visible and invisible during half the year.

Instead of the divisions which we have now described, Ptolemy adopted climates corresponding to the increase of a quarter of an hour in the length of the longest day. The space from the equator to the polar circle would thus be divided into forty-eight instead of twenty-four zones; but as these in the higher latitudes became very narrow, he carried the quarter-hour climates only to the twenty-fourth, that is, to the parallel at which the longest day is eighteen hours. From eighteen to twenty hours he proceeds by half-hour climates; from twenty to twenty-four hours the breadth of the climate is estimated by the difference of a whole hour in the length of the day. The determination of the parallels at which the different climates begin and end is equivalent to this problem: — Having given the length of the longest day to find the latitude of the place? The tangent of the latitude is equal to the sine of the excess of the semi-diurnal arc above a quadrant multiplied into the co-tangent of the obliquity.

Climate, in its most ordinary and general acceptation, embraces all those modifications of the atmosphere by which our organs are sensibly affected; such as temperature, humidity, variations of barometric pressure, the tranquillity of the atmosphere or the effects of winds, the intensity of electric pressure, the purity of the air or its mixture with gaseous emanations more or less salubrious; and lastly, the habitual diaphaneity of the atmosphere, — that serenity of the sky so important on account of the influence which it exercises not only on the radiation of the ground, on the development of organic tissues in vegetables and the ripening of fruits, but also on the *ensemble* of moral sensations which mankind experience in the different zones. There are two general causes on which the climate peculiar to any country principally depends — 1st, its distance from the equator; and 2nd, its altitude above the level of the sea; but their effect is generally modified by many circumstances exerting a partial influence. Among these may be enumerated the configuration and extent of the country; its inclination and local exposure; the direction of the chains of mountains by which it is intersected, or which are in its vicinity; the nature of the soil as it is more or less favourable to radiation and evaporation; the proximity to, or distance from, seas; the action of winds blending the temperatures of different latitudes; and even the changes produced by cultivation. The appreciation of all these causes, which modify the results deduced from the consideration of latitude and elevation alone, and the effect produced by their combined operation, constitutes the science of *climatology*.

Effect of Geographical Position. — The principal part of the temperature enjoyed by any country depends on the heat which it receives directly from the sun. In estimating the amount of solar heat received by any given space on the surface of the earth in the course of a whole year, we may suppose the sun to remain constantly in the equator, because the excess of heat above the mean in summer is exactly balanced by its defect in winter. Now, the effect produced on any given portion of the surface will depend on the number of rays that fall on that surface, and on the obliquity of their direction with respect to it. But the number of rays falling on a zone of any given breadth, a degree for example, is proportional to the cosine of its latitude; and the effect of a single ray in consequence of its oblique impact is diminished also in proportion to the cosine of the latitude; the diminution of the mean temperature, therefore, in going from the equator to the poles, must be proportional to the square of the cosine of the latitude. It hence follows that the variations of the mean temperature must be most rapid about the middle latitude of 45°; and this result of theory agrees perfectly with observation. Within the temperate zone the character of the climate changes rapidly. Thus in the south of France, and in Italy, nearly under the 45th parallel, the region of the vine is found contiguous to that of the olive and fig-tree. On the other hand, very little increase of heat is observed from the tropic to the equator; and at the other extremity of the arc, from the arctic circle to the highest latitude that has been reached, the intensity of cold is not greatly augmented. The law of the square of the cosine gives a variation of only about eight degrees of Fahrenheit's scale from the polar circle to the pole. In the system of climates of western Europe, the mean temperature at the latitude of 45° is about 13° or 13·5° of the centigrade scale (55° to 56° of Fahrenheit). The mean temperature under the equator ought therefore to be, by the theory, 26° or 27° (centigrade); and at any other place it will be found by multiplying the constant number 27 into the square of the cosine of the latitude.

Effect of Altitude. — That a greater degree of cold prevails in the upper regions of the atmosphere than at low levels would be manifest by the snowy covering of the summits of very elevated mountains in all latitudes, even if no direct experiments had been made on the temperature that prevails there. These, however, have been made in great number; and the constant and regular decrease of the temperature in ascending above the surface of the earth, to such altitude at least as can be reached, has not only been fully established, but the law according to which the decrease takes place determined with considerable certainty. According to theory the decrements of heat in ascending the higher regions should follow the same proportion as the decrements of the density; but this law is greatly disturbed by local peculiarities. The variation of temperature at different altitudes is the simultaneous effect of three general causes, — 1st, the absorption of rays of light in their passage through the atmosphere, which is much greater in the dense strata near the surface of the earth than in the upper regions; 2d, the radiation from the surface; and 3d, the ascending current; the two last also producing a greater effect on the strata near the surface. Any circumstance, therefore, which modifies these causes, must also modify the law which connects the decrease of heat with the elevation. It will be slower above the surface of the sea or a country covered with snow than above a desert destitute of vegetables, or a surface of sand; and it will be more rapid above the sloping sides of a conical mountain than over a cordillera which presents plains of great magnitude elevated in stages above one another. Nevertheless at great altitudes the disturbing influences of these causes becomes insensible, and a very considerable degree of uniformity in the temperature constantlyprevails. In the torrid zone, Humboldt, from a mean of many observations, found that between the altitudes of 3000 and 5800 metres (9840 and 19,000 feet) an increase of elevation, amounting to 191·4 metres, produced a diminution of 1° of the centigrade thermometer. This corresponds to 349 English feet for 1° of Fahrenheit. Professor Leslie (*Ency. Brit.* art. "Climate") estimates that the diminution of temperature of 1° of Fahrenheit's scale corresponds to an ascent of 300 feet. But this will hold true only of moderate elevations. At the altitudes of 1 mile, 2 miles, 3 miles, 4 miles, and 5 miles, the increase of elevation corresponding to 1° Fah. will be respectively 295, 277, 252, 223, and 192 feet. The allowance of 1° of Fah. for every 100 yards of ascent is, however, a rule of easy recollection, and in ordinary cases may be taken as a sufficient approximation.

Configuration. — The form of the limits of any large mass of land as determined by its contact with the ocean, that is to say, the greater or less extent of coast it possesses in proportion to its area, exercises a considerable influence on the climate. The small amount of variation in the temperature of the ocean tends to equalize the periodic distribution of heat among the different seasons of the year, and the proximity of a great mass of water moderates by its action on the winds the heat of summer and the cold of winter. Hence the great contrast between the climate of islands and coasts, and the climate of the interior of vast continents. Europe presents a remarkable example of this contrast. From Orleans and Paris to London, Dublin, Edinburgh, and even farther north, the mean temperature of the year decreases very little, notwithstanding the increase of latitude; while in the eastern part of the Continent each degree of latitude, according to Humboldt, produces a variation of 1·1° Fah. in the mean temperature. A small island, a tongue of land, or an indented coast, in contact with a great mass of water, which preserves in winter a considerable portion of the heat acquired during the summer, possesses a more moderate climate, milder winters, and fresher summers, and in the higher latitudes a somewhat higher mean temperature, than the interior of great continuous masses of land under the same latitude. The diminution of the mean annual temperature from the western shores of Europe to beyond the meridian of the Caspian is remarkable. Amsterdam and Warsaw are situated very nearly under the same parallel of latitude, that of the first being 52° 22′, and that of the second 52° 14′; but the mean annual temperature of Amsterdam is 53·4° Fah., while that of Warsaw is only 46·48°. The latitude of Copenhagen is 55° 41′, and that of Kasan 55° 48′; but the mean annual temperature of Copenhagen is 45·7°, that of Kasan 37·6°. The climate of a country is influenced not only by its horizontal configuration, but also by its *relief*, or vertical configuration. Mountains affect the climate of the adjacent plains in various ways — by the reverberation of heat from naked rocks; by affording shelter from certain predominating winds; and by giving rise to descending currents of cold air from the higher regions of the atmosphere, in consequence of the disturbance of the equilibrium of heat produced by the radiation from their sides and summits. The local exposure of a country also, or its inclination to or from the equator, which may be included under the title configuration, has a powerful influence on its mean annual temperature. Generally speaking, the local exposure is connected with

and depends upon the position of the mountain chains, and both conspire to increase or diminish the mean temperature at the same time. For example, when the general inclination of an extensive tract of country is towards the south, the northern side is bounded by ranges of mountains; so that while the sun's rays fall upon it at a less oblique angle, it is sheltered from the cold winds blowing from a higher latitude.

Climate of Europe. — In a general view, Europe may be regarded as a peninsular prolongation of the ancient continent, broken and intersected by numerous arms of the ocean, and by inland seas. The predominating winds are from the west; and these, for the whole of the western portion, are sea winds, greatly softened by blowing over a mass of water, of which the superficial temperature, even in the month of January, at the parallels of 45° and 50°, does not fall below 48° and 51° of Fahrenheit. It is placed directly north of an immense tract of tropical land (Africa and Arabia), which by its diurnal radiation contributes powerfully to elevate the temperature. On the northern side the cold belonging to the latitude is mitigated by numerous favourable circumstances. A very small portion of land lies within the polar circle; and the whole of the northern extremity is separated from the polar ice by a zone of open sea, the temperature of which is maintained at a considerable elevation in consequence of its communication with the Atlantic ocean, and of the existence of the gulf stream, which conveys a portion of the temperature of the gulf of Mexico into the polar seas.

Climate of Asia.—The circumstances which contribute to render the climate of Europe mild and temperate are nearly all reversed in respect of Asia. Its northern boundary extends beyond the parallel of 70°, and in some places reaches to 75°. In every part it extends to the winter limit of the polar ice, and only a very narrow zone of water is interposed between the ice and the land during the short summer of these high latitudes. The north winds, not obstructed by any chain of mountains, blow with unmitigated severity over an icy plain, extending northward to the pole, and eastward to the point of maximum cold, which appears to be situated near the meridian of Behring's straits. The refrigerating influence of these winds is not counteracted by arid deserts on the southern side of the continent. From the meridian of the Ourals to that of Cape Tchoukotski, through 140 degrees of longitude, there is no land under the equator, excepting the inconsiderable portion formed by the islands of Sumatra, Borneo, Celebes, and Gilolo; consequently the Asiatic countries situated in the temperate zone are not warmed by ascending currents of heated air, such as those which rise from the deserts of Africa and are so beneficial to Europe. The position of the great mountain chains and the general elevation of the country also powerfully contribute to diminish the temperature. The Himalaya and Kuen-lun, through a great extent of the continent, present an effectual barrier to the warm winds which come from the equator. Elevated plains and groups of lofty mountains accumulate, and preserve the snow till late in the summer, and give rise to descending currents of air which cool down the temperature of the circumjacent countries. Lastly, Asia being bounded on the western side by Europe, the west or predominating winds are land winds for the greater part of the continent, and their severity is increased by the great enlargement of the land towards the north. (*Humboldt, Fragmens Asiatiques; Daniell's Meteorological Essays; Murray's Ency. of Geography.*)

CLI'MAX. (Gr. κλίμαξ, *gradation.*) In Rhetoric, a figure by which several propositions, or several objects, are placed before the mind of the hearer or reader in such an order that the proposition or object calculated to produce the least impression shall strike it first, and that the rest shall follow in regular gradation. Anti-climax is the converse figure, in which the ideas sink in succession. This forms a principal cause of that vice of composition of which so many ludicrous illustrations have been given under the name of Bathos.

CLINAN'THIUM. (Gr. κλινη, *a bed*, and ανθος, *a flower.*) A term used to express the receptacle of a composite plant. It is the dilated apex of a flowering branch covered over by small flowers enclosed within an involucre.

CLI'NICAL. (Gr. κλινη.) This term is generally used medically; a *clinical lecture*, for instance, is the instruction which the teacher gives his pupil at the bedside of the patient.

CLI'NIUM. (Gr. κλινη.) A term occasionally used in botany to denote the summit of a floral branch, of which the carpella are the termination. It is the same as the *torus* of the modern French school, and one of the parts called receptacle by Linnæus, as in the strawberry.

CLI'NKERS. See BRICKS.

CLI'NOID. (Gr. κλινη, and ειδος, *likeness.*) This term has been improperly applied to certain processes of the *sphenoid bone.*

CLINO'METER. (Gr. κλινω, *I bend*, and μετρον, *a measure.*) An instrument for measuring the *dip* of mineral strata. (*Geol. Trans.* vol. iii.)

CLI'O. (Gr. κλειω, *I celebrate.*) In Mythology, the muse who was usually supposed to preside over history, though she sometimes invaded the province of her sister Calliope, the goddess of epic poetry. In his magnificent ode (Book 1. Ode 12.) addressed to Augustus, Horace invokes Clio as the patroness of the flute or the lyre, or in other words of lyric poetry:—

Quem virum aut heroa lyra vel acri
Tibia sumes celebrare, Clio, &c.

CLIO. In Zoology, applied by Linnæus to a genus of *Vermes*, and by Cuvier to a genus of Pteropodous Mollusks; one species of which, the *Clio borealis*, abounds in the northern seas; and although not exceeding an inch in length, it forms a great proportion of the food of the whalebone whale, *Balœna mysticetus.*

CLOA'CA. (Lat.) The excrementory cavity in which, in birds, reptiles, many fishes, and some mammals, the intestinal canal, urinary ducts, and genital passages terminate.

CLOCK. *See* HOROLOGY.

CLOI'STER (Lat. claustrum.) In Architecture, an arcade or colonnade round an open court.

CLOSE. In Music. *See* CADENCE.

CLOSE. A small field, enclosed or hedged about.

CLO'SE-HAULED; that is, the tacks close down, the sheets aft, the yards braced sharp up, and the bowlines hauled, the ship making her progress as near the direction of the wind as she can.

CLO'SERS. In Architecture, the pieces (or bats), less or greater than half a brick, that are used to close in the end of a course of brickwork. In English as well as Flemish bond (*see* BOND), the length of a brick being but nine inches, and its width four inches and a half, in order that the vertical joint may be broken at the end of the first stretcher, a quarter brick (or bat) must be interposed to preserve the continuity of the bond; this is called a *queen closer.* A similar preservation of the bond may be obtained by inserting a three-quarter bat at the angle in the stretching course; this is called a *king closer.* In both cases a horizontal lap of two inches and a half is left for the next header.

CLOUD. A visible mass or collection of minute particles of water suspended in the atmosphere. Clouds differ from fogs or mists only in occupying a more elevated position; in all cases the origin is the same, namely, the vapours which rise from collections of water, and indeed from the whole surface of the earth. These aqueous vapours are condensed in the higher and colder regions of the atmosphere, and thus lose their transparency and become visible. Clouds differ very greatly in respect of form, magnitude, density, &c. These differences depend on the quantity of vapour of which they are composed, and the situations which they take as they unite with one another; and are determined in a great measure by the direction and velocity of the motion communicated to them by the wind. The height at which they float in the atmosphere is determined by their specific gravity, and consequently varies with their density. Thin light clouds are observed higher than the summits of the loftiest mountains, while those which are dense and thick rise only to a small distance above the surface of the earth. It is very difficult to determine their average elevation: it is supposed to be between two and three miles, but it varies at different times of the year.

Clouds were distributed by Mr. Luke Howard into three primary formations,—the *Cirrus*, the *Cumulus*, and the *Stratus.* But besides these he admitted four other varieties,—the *Cirro-cumulus*, the *Cirro-stratus*, the *Cumulo-stratus*, and the *Cumulo-cirrostratus* or *Nimbus.* The *Cirrus* consists of fibres or curling streaks, which diverge in all directions. It occupies the highest region, and is frequently the first cloud which is seen after a continuance of clear weather. The *Cumulus* is a convex aggregate of watery particles, increasing upwards from a horizontal base, and assuming more or less of a conical figure. The *Stratus* consists of horizontal layers, and comprehends fogs and mists. It is the lowest of the clouds, its under surface usually resting on the earth or water. The *Cirro-cumulus* is intermediate between the cirrus and cumulus, and is composed of small well-defined masses closely arranged. The *Cirro-stratus*, intermediate between the cirrus and stratus, consists of horizontal masses separated into groups, with which the sky is sometimes so mottled as to suggest the idea of resemblance to the back of the mackarel. The prevalence of the cirro-stratus is usually followed by bad weather. The *Cumulo-stratus*, or *twain cloud*, partakes of the appearance of the cumulus and stratus or cirro-stratus. The *Nimbus*, or *rain cloud*, is that into which the others resolve themselves when rain falls.

The above nomenclature is sufficiently fanciful; nevertheless it enables the meteorologist to convey more precise ideas in describing the diversified forms under which masses of clouds present themselves and their connection with the changes of the weather. These

forms are, however, frequently so indefinite and shapeless, that it is difficult, if not impossible, to refer them to any one of the preceding modifications. A tendency, however, to one or other of them may in general be traced. (*Howard's Arrangement and Nomenclature of Clouds*, in the 16th and 17th vols. of the *Philosophical Magazine; Foster on Atmospheric Phenomena; Murray's Encyclopedia of Geography*, p. 168.; *Companion to the British Almanac* for 1830, &c. See also *Dalton's Meteorological Essays*, 1793.)

CLOU'TED or CLO'TTED CREAM. The cream produced on the surface of milk by setting a pan of new milk on a hot hearth is so named. It is chiefly used as a kind of entremet, and, when mixed with new milk, is eaten along with fruit pies, strawberries, raspberries, &c.: it is also eaten without milk, spread on bread.

CLOVES. (Lat. clavus, *a nail.*) The smaller bulbs formed in the axillæ of the scales of a mother bulb, as in garlic.

CLOVES. The unexpanded flower-buds of the *Caryophyllus aromaticus*, a low branching tree cultivated in the Dutch settlements in India. The finest cloves are from Amboyna; they are of a bright brown colour, extremely fragrant, and hot and acrid upon the tongue; they abound in essential oil, which may be pressed out of their pores by the nail, and which is generally obtained by distillation with water, to the amount of from 15 to 20 *per cent.* It is sold in commerce under the name of *oil of cloves*, and chiefly used in medicine, and occasionally in perfumery. The fruit of the clove tree was employed in old pharmacy under the name of *anthophylli.*

CLUBS *See* SOCIETIES.

CLUB MOSS. (*Lycopodium clavatum.*) The seeds of this moss, which are very minute, and resemble an impalpable yellow powder, are used in theatres to imitate lightning; when thrown across a flame, they produce a sudden flare: they contain a peculiar oil.

CLUMP. A mass of trees or shrubs, or both, generally roundish and compact in its outline, and always small as compared with extensive plantations. The word appears to have been first used in planting and gardening in the time of the celebrated landscape gardener Brown, about the middle of the 18th century. Brown distributed his clumps at irregular distances over the entire surface of any piece of ground that was intended to be made a park; surrounding the park at the same time with a belt of plantation. The intention of Brown in planting these clumps was to nurse up a few trees in each clump, which should remain as groups or single objects after all the other trees of the clump were removed; but as thinning and the removal of the boundary fence of these clumps very seldom took place, they have grown up in most cases deformities rather than beauties. The term clump as applied to a plantation has long since become one of reproach.

CLUMP. The compressed clay of coal strata.

CLYPEA'STER. (Lat. clypeus, *a buckler*, and astrum, *a star.*) A genus of sea-urchins (*Echinidæ*) of a flattened, shield-like form, with a submarginal vent. This genus is termed *Echinanthus* by Klein.

CLY'PEATE. (Lat. clypeus.) Shield-like: it is the same as scutate.

CLY'SSUS. An alchemical name for the water obtained by deflagrating nitre with charcoal: the vessels were generally burst in the operation; but when it succeeded the few drops of water obtained were highly prized for medical use.

COACE'RVATE. (Lat. con, *together*, and acervus, *a heap.*) Accumulated. A term applied by older physiologists to certain secretions or excretions long retained.

COADJU'TOR. In Ecclesiastical matters, the assistant of a bishop or other prelate (in some instances even of a canon or prebendary, but the latter usage was irregular). These assistants, in France and other countries, were instituted by the pope. A coadjutor was equal in rank to the dignitary whose functions he might on occasion supply; hence the coadjutor of a bishop was himself consecrated a bishop *in partibus infidelium.* The celebrated Cardinal de Retz was known by the title of the Coadjutor of Paris during the most active period of his career, having the administration of the temporalities of that see, which belonged to his uncle the Archbishop de Retz. Coadjutors usually succeeded their principals in their dignities; and hence arose an abuse which tended towards making ecclesiastical dignities hereditary, nephews and other relatives of bishops being named their coadjutors. The institution of coadjutors to bishoprics is preserved by the French concordat of 1801.

COA'DUNATE. (Lat. con, ad, and una, *together.*) Two or more parts joined together.

COAL. (Germ. kohle.) This highly important substance is found in beds or strata in that group of the secondary rocks which includes the red sandstone and mountain limestone formations, and which is commonly called the *carboniferous group*, or *coal measures*. From the peculiarities of their deposition they are often spoken of under the names of *coal basins*, and *coal fields*. There are two or three points, and those of much theoretical importance, respecting the origin of coal, on which geological authorities are nearly unanimous. The one is, that our present coal is exclusively of vegetable origin, formed apparently from the destruction of vast forests; and the prodigious quantities of timber drifted by some of the great rivers of the world into the present ocean render it not improbable that a similar formation may now be carrying on in the depths of certain parts of the sea. Secondly, from the nature of the preserved vegetables it appears probable that the climate of these parts was not merely tropical, but ultratropical. It may also be inferred that the coal strata were deposited in the neighbourhood, and often probably upon the verge, of extensive tracts of dry land; for the trees that are found in coal strata are often like those of *our* submarine forests, as far as position goes. And, finally, the deposits of coal appear afterwards to have been elevated, and often singularly dislocated and contorted by forces acting from below, and probably of a volcanic nature.

In some coal fields there are appearances which justify the term *coal basin:* they are of limited extent, frequently dip as it were to a common centre, and consist of various beds of sandstone, shale, and coal, irregularly stratified; and sometimes mixed with conglomerates, showing a mechanical origin.

That these deposits have taken place, and that the change of wood into coal has often been effected under great pressure, and often under pressure and heat, seems evident from the appearance of some of the vegetable masses, and also from the manner in which the carburetted hydrogen escapes in the form of *blowers* and eructations from the strata, as if pent up in their cavities under vast condensation, and even sometimes, perhaps, in a liquid form.

Though there are often many beds and seams of coal in one field, it is seldom that many of them are worked. They are generally of uniform thickness through a great extent, but are sometimes subject to irregularities. When less than two feet thick they are seldom worked to any great extent. The nature of the upper stratum, or stony matter of the *roof*, is very important: if compact, it is secure from falling, and keeps out water; if loose, the expense incurred in supporting it absorbs the profits of the coal.

The deepest coal mines in England are those of Northumberland and Durham, which are worked nearly 1000 feet below the surface. The thickest bed of coal is said to be at Wood Mill Hill colliery in Staffordshire, and to exceed 40 feet. From 6 to 9 feet is the average thickness of the most productive seams. The coal generally most esteemed is that of the northern districts, — Northumberland, Durham, and Yorkshire. It abounds in bitumen, softens and swells in the fire, and throws out jets of flame; it coheres, and therefore burns hollow and requires poking; it furnishes cinders, and but little ash. Most of the coal from the west of England blazes and burns briskly, being much more easily kindled than the other; it requires no poking, because it has no tendency to cake; it affords no cinders, and leaves a dusty white ash. *Culm* contains scarcely any bitumen; it abounds in earthy matter, and somewhat resembles bad coke.

Coal is the most valuable of all the mineral substances from which Britain derives her prosperity, and, indeed, may be regarded as the main support of the whole system of British production. It fuses the metals, produces the steam which sets the machinery in motion, and, in short, may be said to render all the resources of this country available for use. The annual consumption of coal, throughout the British Empire, is estimated at 28,575,000 tons. The coal trade gives occupation to nearly 200,000 persons. In 1838, the total quantity of coal shipped was 7,190,433 tons: of which, from the Tyne and Wear, 4,628,000; South Wales, 1,228,300; Whitehaven, 395,000. The export was 2,449,417 tons, chiefly to Ireland, France, the Netherlands, Germany, Denmark, British America, and the United States. The imports into London in 1839 amounted to 2,638,256 tons, brought by 7500 vessels.

CO'BALT. (Germ. kobold, *a devil.*) A term applied to this metal by the German miners, who considered it unfavourable to the presence of the more important metals.

Cobalt is a brittle metal of a reddish grey colour; its specific gravity is 7·8. It fuses at a temperature a little below that required for the fusion of iron. It is magnetic. When heated red hot, and freely exposed to air, cobalt absorbs oxygen. Its equivalent number is 30; and the salifiable, or protoxide of cobalt, consists of 30 cobalt + 8 oxygen = 38 oxide of cobalt. The oxide of cobalt is nearly black; but when in the state of hydrate, or when largely diluted by fusion with glass or borax, it produces its characteristic blue colour; and as this colour is permanent at very high temperatures, it is an invaluable article in the manufacture of porcelain and pottery, all the blue colours of which are derived from oxide of cobalt. When fused with glass it communicates a blue tint without impairing its transparency. A very deep blue

glass of this kind when finely powdered acquires a pale and brilliant colour, and is called *smalt*. Impure oxide of cobalt is known in commerce under the name of *zaffre*. Cobalt is said by Stromeyer to exist in all meteoric iron, although in very small quantity. In its ores it is always associated with arsenic, and zaffre is prepared by roasting these native arseniurets of cobalt.

CO'BBLES. Lumps of coal from the size of an egg to that of a football.

COBI'TIS. (Lat. cobio, *a gudgeon.*) A genus of soft-finned fishes, belonging to the *Cyprinidæ* or carp family; and characterized by a small head; an elongated body; the skin covered with small scales; ventral fins placed far backwards, with one small dorsal fin above them; mouth small and toothless; gill-openings very small, and with three rays. Of this genus the loche (*Cobitis barbatula*) inhabits the clear running streams of Britain. The pond loche (*Cobitis fossilis*) is a larger species. It is remarkably sensitive to atmospheric changes, and when confined in a glass-globe may be observed to sink to the bottom in a state of quiescence when the weather is cold and gloomy; but in boisterous weather it comes to the surface and swims about with great rapidity. It also swallows air, which it discharges from the vent, partly converted into carbonic acid gas.

CO'BLE. A small boat or canoe, used chiefly on the rivers and lakes of Wales, and the borders.

CO'B-WALLS. Walls formed of mud mixed with straw; not uncommon in some districts of England. The best cob-walls are in Somersetshire.

COCCINE'LLA. (Dim. of Lat. coccinus, *crimson.*) A genus of Trimerous Coleopterous insects, including many small species, usually ornamented with scarlet spots, and familiarly known as lady-birds, lady-cows, &c. In France these small beetles are dedicated to the Virgin, and called Bêtes de la Vièrge. They are, in fact, of great service to the agriculturist, and especially to the hop-grower; for they destroy the *Aphides*, or plant-lice, in vast numbers, feeding on them both in the larva and perfect state.

CO'CCOLITE. (Gr. κοκκος, *a grain*, and λιθος, *stone.*) A mineral of a concretional or granular texture.

COCCOO'N. The silken case which the larvæ of certain insects spin for the purpose of a covering during the period of their metamorphosis, and which some spiders prepare as a protection to their ova during the development of the young. The cod or coccoon of the silk-worm is a well-known example of the most valuable of these productions.

CO'CCULUS INDICUS. The fruit of the *Menispermum cocculus*, imported from the East Indies. It contains a poisonous principle, which has been termed *picrotoxia*. It is often used to poison fishes: a few handfuls of it ground into coarse powder, and thrown into a pond, bring the fish, in the course of a few hours, to the surface in an intoxicated or poisoned state; but if quickly removed into fresh water, they recover. It is sometimes added to ale to increase its stupefying quality.

CO'CCUM. (Gr. κοκκων, *a pomegranate stone.*) A term invented by Gærtner to denote a pericarp of dry elastic pieces or cocci, as in Diosnia, &c.

CO'CCUS. (Lat. coccus, *scarlet cloth.*) A name given by Linnæus to a genus of Hemipterous insects, including the Mexican species, the cochineal insect (*Coccus cacti*, L.), which feeds on *Cacteæ*, and which affords the well-known fine red dye.

CO'CHINEAL. The *Coccus cacti*. This valuable insect was first introduced into Europe about the year 1523. It is imported from Mexico and New Spain. It feeds on several species of cactus. It is small, rugose, and of a deep mulberry colour. They are scraped from the plants into bags, killed by boiling water, and dried in the sun. Those are preferred which are plump, of a peculiar silvery appearance, and which yield a brilliant crimson when rubbed to powder. Cochineal is sometimes adulterated by the admixture of a manufactured article composed of coloured dough. This is detected by the action of boiling water, which dissolves and disintegrates the imitation, but has little effect upon the real insect. The principal component of cochineal is a peculiar colouring matter, which has been called *carminium* and *cochinelia*. It is obtained by digesting the powder of cochineal first in ether, which takes up fat, and then in alcohol, which dissolves the cochinelia. Acids change its colour from crimson to an orange red, and alkalies turn it violet. When mixed with recently precipitated aluminous earth, it forms a beautiful lake. Cochineal yields a brilliant scarlet dye, which is produced by fixing the colouring matter of the insect by a mordant of alumina and oxide of tin, and exalting the colour by the action of supertartrate of potash.

CO'CHLEAN. (Lat. cochlear, *a spoon.*) A term used in describing the æstivation of a flower, to express one piece being larger than the others, and hollowed like a helmet or bowl, covering all the others, as in Aconitum, &c.

COCHLEARE. A spoon; the bowls of spoons being formerly made of the shape of a cockle-shell, and often fluted.

COCHLEA'TE. (Lat. cochlea, *a shell*, *a cockle.*) A term used in describing the general form of bodies, to denote any that are twisted in a short spire, so as to resemble the convolutions of a snail-shell; as the pod of *Medicago cochleata*. It also means a concave body like that of one of the valves of a cockle-shell, as in *Epidendrum cochleatum*.

CO'CKET. In Commerce, a scroll of parchment, signed and delivered by the officers of the custom-house to merchants upon entering their goods, to certify that their merchandise is customed and may be discharged.

CO'CKLE-OAST. That part of a hop-kiln or oast where the fire is made.

CO'CK-LOFT. The highest loft, or garret, in any building.

CO'CKNEY. A contemptuous appellation of a citizen of London. Various derivations have been assigned to this word, all of which are more distinguished for ingenuity than probability. But whatever may be the origin of the term, its antiquity cannot be disputed, as it is mentioned in some verses generally attributed to Hugh Bagot, Earl of Norfolk, in the reign of Henry II.: —

> Were I in my castle at Bungey,
> Upon the river of Waverney,
> I would ne care for the king of Cockeney (*i. e.* of London).

CO'CK-PIT. The after part of the orlop deck, or deck below the lower deck, and altogether below the water. Here, in line-of-battle ships, are the cabins of several of the officers. The cock-pit is appropriated to the use of the wounded in time of action. There is also a fore cock-pit in the fore part of the ship, and sometimes an after cock-pit.

Cock-Pit is the name given to the place where game cocks fight their battles. The room in Westminster in which her Majesty's privy council hold their sittings is called the *cock-pit*, from its having been the site of what was formerly the cock-pit belonging to the palace at Whitehall.

COCY'TUS. (Gr. κωκυτός, *lamentation;* from κωκύω, *I bewail.*) In Mythology, the river of Lamentations, which was one of the streams that washed the shores of the mythological hell, and prevented the imprisoned souls from returning to the earth. Milton alludes to it thus (*Par. Lost*, book ii.): —

> Cocytus named of lamentations loud
> Heard on the rueful stream.

CO'DA. (It. coda, *a tail.*) In Music, the passage at the end of a movement which follows a lengthened perfect cadence. In some cases it consists of merely one phrase, in others it is carried to a great extent. At the conclusion of a canon or fugue, it often serves to end the piece which might otherwise be carried on to infinity.

CODE (from the Latin codex, *a manuscript*), signifies, in the language of jurisprudence, any collection of laws digested and reduced into an orderly arrangement, whether by public authority or by the private labour of learned men. But, in the ordinary sense, the word Code is only used to signify a compilation of laws by authority. Five collections of Roman law are designated by the title of *codes*: — that of Sextus Papirius, which only exists in fragments discovered by various authors, but which contained the laws of the Roman kings; the Gregorian, the compilation of an unknown author, about the reign of Constantine; the Hermogenian, of which the author is also doubtful, and the date nearly the same; the Theodosian, framed under the order of the emperor Theodosius the younger, and containing the constitutions of the emperors from the time of Constantine to his own (from which, until the greater works of Justinian became publicly known in modern Europe, the jurisconsults of the dark ages drew the greater part of their knowledge of Roman law); and, lastly, that of Justinian, A. D. 529. Of the codes of law now recognised in modern states the most remarkable are, in order of time — the code of Frederic the Great of Prussia; that of Catherine of Russia, confined to criminal jurisprudence; that of Joseph II. of Austria; and the Code Napoleon in France. This title, though sometimes given in general language to all the digests of law made under that emperor, is appropriated by French lawyers to the greatest of his works, the Code Civil. The project for this code was drawn up, in 1801, by five commissioners, by them reported to the Court of Cassation, and thence carried to the Conseil d'Etat: in that body it was fully discussed, clause by clause. Besides the Code Civil, the written French law comprises five other codes; viz. the Code Pénal; the two Codes of Procedure, civil and criminal; the Code de Commerce; and, finally, the Code Forestier, or collection of laws relative to the administration of the woods, published in 1827 under Charles X.

CODE'INE, or CODEIA. (Gr. κωδια, *the poppy head.*) An alkaline substance, discovered in 1832 by Robiquet in opium. It was at first confounded with morphia.

CODE'TTA. (Dimin. of coda.) In Music, a short

passage which connects one section with another, and not composing part of a regular section.

CO'DEX. A manuscript: in its original sense (Latin) the inner bark of a tree, which was used for the purposes of writing. The word was thence transferred by the Romans to signify a piece of writing, on whatever material; *e. g.* with the stylus on tablets lined with wax, or on a roll of parchment or paper. In modern Latin, a manuscript volume. *Codex rescriptus* or *palimpsestus* is a manuscript consisting of leaves, from which some earlier writing has been erased in order to afford room for the insertion of more recent. Many such codices exist; and from the imperfect nature of the erasing process, the earlier writing has in some instances been restored. Considerable fragments of classical works, previously considered as lost, have been thus recovered by the Abate Mai from among the contents of the Ambrosian Library at Milan.

CO'DICIL. (Lat. codicillus, diminutive of codex, *a manuscript.*) In Law, an addition or supplement to a will, for the purpose of altering, explaining, or adding to its contents. Of codicils, as of wills, the latter prevails where it contains provisions contradictory to those of a former. By the recent Wills Act (1 Vict. c. 26.), every codicil must be executed in the same manner as is thereby made requisite in the case of a will; viz. signed by the testator in the presence of two witnesses at one time. *See* WILL.

COEFFI'CIENT. In Algebra, a number or known quantity prefixed as a multiplier to a variable or an unknown quantity. Thus, in the equation $a x^m + 6 b x^n = o$, a is the multiplier or *coefficient* of x^m, and $6 b$ is the *coefficient* of x^n. When no number or coefficient is prefixed, unity or 1 is understood. *See* EQUATION.

CŒLACA'NTHIDÆ. (Gr. κοιλος, *hollow*, and ακανθος, *a spine.*) A family of Ganoid fishes in the system of Agassiz; so called on account of the species composing it being armed with hollow spines. The following interesting fossil genera, *Holoptychius* and *Cœlacanthus* proper, belong to this family.

CŒ'LELMI'NTHA. (Gr. κοιλος, and ἑλμινς, *a worm.*) The name of a class of Entozoa, including part of the cavitary intestinal worms of Cuvier, or those which are characterized by having an alimentary canal contained in a distinct abdominal cavity.

CŒLE'STINE. A mineralogical name of *sulphate of strontia* (from its blue tint).

CŒ'LIAC. (Gr. κοιλια, *the belly.*) A painful species of diarrhœa has been by some medical writers called the *cœliac passion*. The cœliac artery is the first branch of the aorta in the abdomen.

CŒNA'CULUM. (Lat.) In ancient Architecture, the eating or supper room of the Romans. In the early periods of the Roman history, the upper story of their houses, which rarely consisted of more than two, seems to have been called by this name.

CŒNA'TIO. (Lat.) In ancient Architecture, an apartment for taking refreshment in the lower part of the Roman houses.

CŒNO'BIO. (Gr. κοινος, *common*, and βιος, *life.*) A name invented by the French botanists, to distinguish that class of fruits which consists of two or more carpels separate at the apex and united at the base, from the middle of which a single style arises. It occurs in Lamiaceæ, &c.

CŒ'NOBITE. (Gr. κοινος, and βιος, *life.*) One who lives under a rule in a religious community, as distinguished from an anchoret or hermit, who lives in solitude. *See* ANCHORET.

CŒ'NURE, *Cœnurus*. (Gr. κοινος, and ουρα, *a tail.*) The hydatid which infests the brain of sheep is so called, because the dilated cyst is the common termination or basis of attachment of many heads and bodies. The disease called "staggers" is produced by this parasite.

CO'FFEE. The berries of the *Coffea arabica*. These, when roasted, powdered, and infused in boiling water, yield the well-known beverage called coffee. It is exhilarating, and operates upon many persons as an aperient. *See* CAFFEIN.

CO'FFER. (Sax. copne.) In Architecture, a sunk panel in vaults and domes, and also in the soffit or under side of the Corinthian cornice, usually decorated in the centre with a flower.

CO'FFER-DAM. In Architecture, and Bridge-building, a case of piling, water-tight, fixed in the bed of a river for the purpose of laying the bottom dry for a space large enough to build the pier on. Coffer-dams are formed in various ways, either by a single inclosure or a double one, with clay or chalk rammed in between the two to prevent the water from coming through the sides. They are also made either with piles only, driven close together, and sometimes notched or dovetailed into one another; or, if the water is not very deep, by piles driven at a distance of five or six feet from each other, and grooved in the sides with boards let down between them in the grooves. In order to build in coffer-dams a very good natural bottom of solid earth or clay is required; for though the sides be made water-tight, if the bed of the river be of a loose consistence, the water will ooze up through it in too great a quantity to permit the operations to be carried on. It is almost needless to remark that the sides must be very strong, and well braced in the inside to resist the pressure of the ambient water. (*Hutton's Tracts* vol. i.)

CO'GNIZANCE, *Conusance*. In Law, an acknowledgment of a fine, of taking a distress, &c. It also signifies the power which a court has to hear and determine a particular species of suit.

COGNO'MEN. In Antiquities, the last of the three names by which all Romans, at least those of good family, were designated. It served to mark the house (*see* FAMILIA) to which they belonged, as the other two names, viz. the *prænomen* and *nomen*, served respectively to denote the individual and the class (*see* GENS) to which his family belonged.

COGNO'VIT. (Lat.) In Law, is a confession whereby a defendant admits that the plaintiff's cause of action against him is just (cognovit actionem), and suffers judgment to be entered against him without trial.

COHE'SION. (Lat. cohæreo, *I hold together.*) In Natural Philosophy, is the force or attraction with which the particles of homogeneous bodies are kept attached to each other, or with which they resist separation. Cohesion is thus distinguished from *adhesion;* the latter term denoting the attractive force existing between two different bodies brought into contact, as a drop of water on a plate of glass; or between two bodies of the same matter, as two lumps of lead, when their smooth surfaces have been pressed together. The three different forms which matter assumes, — solid, liquid, and gaseous, — are determined by the degree of cohesive force existing among the elementary particles. In solids this force is great, and, in fact, is that which causes solidity; in liquids it is less powerful, but still sufficiently manifest in the *drops* or globular form assumed by small quantities of water or mercury poured on a table. In the case of aeriform fluids it may be regarded as negative, the particles having a tendency to repel each other. The cohesive force of the elementery particles of matter depends on the distances of the particles from each other; but of the law according to which its intensity increases or diminishes nothing is known, excepting that the force decreases rapidly as the distance increases, and vanishes altogether when the distance becomes so great as to be appreciable to the senses.

It is a problem of very great importance to determine the cohesive power of the materials employed in mechanical structures. Numerous experiments have been made for this purpose; and their results have not only a practical utility, but throw much light on the constitution of bodies. When a bar of metal, a beam of wood, or a rope is stretched lengthwise, the tension which it bears, or the cohesive power evolved, is equal to the accumulated attraction of all the particles in any transverse section. The longitudinal distension which takes place before disrupture is at first proportional to this attraction, but afterwards increases in a more rapid progression. "A bar of soft iron will stretch uniformly by continuing to append to it equal weights till it be loaded with half as much as it can bear; beyond that limit, however, its extension will become doubled by each addition of the eighth part of the disruptive force. Suppose the bar to be an inch square, and 1000 inches in length; 36,000 lbs. avoirdupois will draw it out one inch, but 45,000 lbs. will stretch it 2 inches, 54,000 lbs. 4 inches, 63,000 lbs. 8 inches, and 72,000 lbs. 16 inches, where it would finally break." (*Leslie's Nat. Philosophy.*)

The following is a tabular view of the absolute cohesion of the principal kinds of timber employed in building and carpentry, showing the load which would rend a prism of an inch square, and the length of the prism which, if suspended, would be torn asunder by its own weight: —

Teak	12,915 lbs.	36,049 feet.
Oak	11,880	32,900
Sycamore	9,630	35,800
Beech	12,225	38,940
Ash	14,130	42,080
Elm	9,720	39,050
Memel fir	9,540	40,500
Christiana deal	12,346	55,500
Larch	12,240	42,160

The above numbers must be regarded as only approximative, and representing the average cohesive force of the different kinds of wood specified; for the force differs greatly in different specimens of the same sort, and even in different parts of the same timber. Thus in the tables given by Professor Barlow of experiments on the direct cohesion of different woods, we find the weight required to tear asunder a prism of an inch square varying as under: — Fir, from 11,000 to 13,448 lbs.; ash, from

15,784 to 17,850 lbs.; oak, from 8,889 to 12008 lbs.; teak, from 14,662 to 15,405 lbs.; pear, from 8,834 to 11,537 lbs., &c. (*Barlow on the Strength of Materials*, 1837.)

The metals differ more widely from each other in their cohesive strength than the several species of wood or vegetable fibres. According to the experiments of Mr. George Rennie in 1817, the cohesive power of a rod an inch square of different metals, in pounds avoirdupois, with the corresponding length in feet, is as follows: —

Cast steel - -	134,256 lbs.	—	39,455 feet.
Swedish malleable iron	72,064	—	19,740
English ditto - -	55,872	—	16,938
Cast iron - - - -	19,096	—	6,110
Cast copper - -	19,072	—	5,003
Yellow brass - -	17,958	—	5,180
Cast tin - - -	4,736	—	1,496
Cast lead - - - -	1,824	—	348

It is difficult to measure directly the cohesion of fluids (and it is very considerably affected by the temperature); but an approximation may be derived from the magnitude of drops, and the thickness of liquid sheets, heaped upon a horizontal surface. In this view, says Professor Leslie, let us trace the formation of a drop of water as it slowly collects at the end of a capillary siphon. The mutual attraction of the particles always rounds the under part of the pendant fluid, which continues to lengthen till its accumulating weight begins to overcome the cohesion of the particles. But this force being 75 grains for each horizontal square inch, while a cubical inch of water weighs 252½ grains, must correspond to the pull of a cylinder of ·18 inch high, which will influence also the breadth of the pendant liquid. Beyond this limit a separation will ensue, when the cylinder merges into a sphere a little wider, or about 2-10ths of an inch diameter.

The cohesion among the particles of alcohol and of sulphuric acid being respectively the fifth part of 215 and 460 grains, the weight of a cubic inch of each of these fluids, a drop of them should measure ·17 of an inch in diameter. The cohesive force of quicksilver at the ordinary temperature amounts to 312 grains on each horizontal inch, while a cubic inch of it weighs 3424 grains; the drop must separate when its mean depth approaches to the 9-100th part of an inch. (*Elements of Nat. Philosophy*, p. 369.)

With respect to the ultimate agent by which the effects of cohesion are produced, it is remarked by Dr. T. Young, that if it is allowable to seek for any other agent than a fundamental property of matter, appearances extremely similar might be derived from the pressure of a universal medium of great elasticity. But all suppositions founded on such analogies must be considered as merely conjectural; and our knowledge of every thing which relates to the intimate constitution of matter, partly from the intricacy of the subject, and partly for want of sufficient experiments, is at present in a state of great uncertainty and imperfection. (*Young's Lectures on Nat. Philosophy*, vol. i. p. 630.) *See* Strength of Materials.

COHOBA'TION. The repeated distillation of the same liquid from the same materials. The term was invented by Paracelsus.

CO'HORT. The tenth part of a Roman legion. (*See* Legion.) The *Prætorian cohort* was a body of picked troops who attended the general, and was first instituted by Scipio Africanus.

COI'NAGE. Under this term we shall give a brief outline of the proceedings in reference to the manufacture of coin, as carried on in the Royal Mint of London.

When a parcel of gold is brought to the mint in ingots, they are deposited with the master's assay-master, who makes an assay of each ingot; and when he is ready to deliver his reports upon them, the importers are required to attend at the mint, where the weigher and teller reads over the said reports to them. They are then recorded in the journals of the master, comptroller, and master's first clerk and melter; and a mint bill is given to the importer, certifying the weight, fineness, and value of the ingots, and signed by the deputy master, comptroller, and king's (or queen's) clerk, which bill is returned upon the delivery of the bullion to the importers in the state of coin. The bullion is then delivered to the melter, who, guided by the assayer's report, adds either alloy or fine gold (when either are required), so as to reduce the mass to *standard fineness* (that is, 22 parts of pure gold and 2 of alloy), and melts and casts the metal into bars of convenient form for rolling; each bar, when intended for coinage in sovereigns, being an inch and a half by one inch square, and about two feet in length, and weighing about 26 pounds. A piece is then taken from each extremity of each bar and delivered to the king's assay-master, whose duty it is to ascertain that the said bars are of standard fineness before he allows them to be delivered to the moneyers, who next receive them for the purpose of coinage.

These preliminary operations are nearly the same as regards silver bullion.

When the moneyers, or responsible manufacturers of the coin, receive bars from the melter, they are rolled and drawn into plates of proper thickness, which require to be most nicely adjusted, so that a piece of proper size punched out of any part of the plate may have the exact weight of the intended coin; the *blanks* are then cut out of these plates, which are thus reduced to the state of *scissel*, and remelted (under due checks and precautions), to be again cast into bars. The blanks (amounting to about two thirds, and the scissel to one third of the weight of the original plate of metal) are next annealed, and passed through the *marking machine*, by which the edge of each piece is made smooth and a little raised; they are then cleaned or *blanched* by being put for a few minutes into a hot and very dilute sulphuric acid, after which they are thoroughly washed and dried, and are ready to be *stamped* or coined. This operation is performed in presses moved by mechanical power, and consists in placing the blanks between two steel dies, upon one of which is engraved the obverse and upon the other the reverse of the coin, so as to give an impression in relief; while the spreading of the piece in a lateral direction is prevented by the rising of a collar at the moment the blow is struck, in which collar is engraved the *milling*, which is thus transferred to the edge of the piece at the same moment that the impressions of the dies are taken upon its two surfaces. The coining presses at the mint are attended by boys, who only have to fill a tube or species of hopper with the blanks; the operation of laying the blank upon the dies, and again throwing it off when stamped, being effected by the machinery connected with the press, thus preventing the risk of crushing the fingers of the persons who used to be employed in this department before these *layers on*, as they are technically called, were adopted. In the coining room at the mint there are eight presses, each adapted for every species of coin; each press strikes upon an average 60 pieces per minute, or 3600 per hour; so that in the day's work of 10 hours each press produces 36,000 pieces; and the eight presses (supposing, which is rarely the case, that they are all in use) stamp 288,000 pieces daily. The money when thus completed is weighed up in what are called *journey weights* for delivery to the importers of the bullion; the gold in 15 lbs. and the silver in 60 lbs. troy. But, before any coin is suffered to pass out of the mint, it is inspected as to its workmanship; and if any journeys are faulty or imperfect in this respect, they may be cut and returned to the moneyers for recoinage. The weight and fineness of the money are also ultimately examined and insured by the process of *pixing*, which consists in taking promiscuously from every journey weight of coin a pound in tale, which is delivered by the weigher and teller to the king's assay-master, who carefully weighs it, and declares aloud the *minus* or *plus* upon each pound (if it be not *standard* or exact), which is recorded by the king's assayer, by the comptroller, and by the king's clerk. This determines whether the moneyers have made the money within the *remedy* allowed upon the pound troy; but, as the remedy upon the pound is divided among the number of pieces in it, the comptroller weighs several of the pieces individually, and if they are not within the allowed limits, can, in conjunction with the other check officers assembled on this duty, return the coin to the moneyers to be remelted and recoined at their expense. From the same pound weight of gold or silver the comptroller also takes two pieces, one of which is handed to the king's assay-master to assay, in order to prove that the metal has undergone no deterioration in any of the processes of its manufacture; the other piece is sealed up in a packet and consigned to the *pix box*, which is locked by the separate keys of the check officers, where it remains until the *trial of the pix* by jury before the king or certain of his council, which usually takes place once every three or four years in the Court of Exchequer at Westminster.

The term journey weight is applied at the mint to the weight of certain parcels of coin, which were probably considered formerly as a day's work. The journey of gold is 15 troy pounds, which is coined into 701 sovereigns, or 1402 half sovereigns. A journey of silver weighs 60 lbs. troy, and is coined into 792 crowns, or 1584 half crowns, or 3960 shillings, or 7920 sixpences.

COINS. *See* Numismatics. Money.

COKE. The charcoal obtained by heating coal with the imperfect access of air, or by its distillation. The former is usually called *oven coke;* the latter *gas coke*, being abundantly produced in gas-works. The weight of coke usually amounts to between 60 and 70 *per cent.* of the coal employed. Coke is a valuable fuel for many purposes in the arts.

COL'CHICUM. (From Colchis in Armenia, where the plant is said to have abounded.) This term is generally applied to the cormus or bulb of the *Colchicum autumnale*, or *meadow saffron*, a plant common in this country, and largely collected for medical use. It was much employed formerly as a diuretic in dropsy; then fell into disuse; and more recently again largely prescribed for the cure of gout, it having been ascertained that the celebrated French remedy for gout called *Eau*

medicinale d'Husson was a tincture of colchicum. Its efficacy may probably be ascribed to the presence of a peculiar alkaloid, which has been termed *colchicia*. When the cormi are intended for medical use, they should be dug up in summer (July), and immediately cut into thin transverse slices, placed separately upon paper, and dried by a very gentle heat. The best preparation is the *wine of colchicum*, made by infusing an ounce and a half of the bulb prepared and dried as above, and coarsely powdered, in 12 ounces of sherry, for six or seven days, shaking it daily: then filter it for use. The dose is from 20 drops to 1 drachm, taken at bed-time in a little water.

COLCO'THAR. A red oxide of iron, being the residue of the distillation of green vitriol or sulphate of iron.

COLD. In Natural Philosophy. *See* HEAT.

COLD. In Medicine. *See* CATARRH.

CO'LEOPHY'LLUM. (Gr. κολεος, *a sheath*, and φυλλον, *a leaf*.) A term introduced into botany, to indicate a monocotyledonous structure, the young leaves being evolved from within a sheath, while those of Dicotyledons are always naked.

COLEO'PTERANS, *Coleoptera*. (Gr. κολεος, and πτερον, *sheath-winged*.) The name of the order of insects comprehending those in which the first pair of wings have the consistence of horn, and serve as defensive coverings to the second pair, or true wings, which are of large size, and are folded transversely when not in use.

By means of this mechanism the *Coleoptera* are enabled to burrow in the soil, or bore the trunks of trees, without injury to their delicate organs of flight, which are the true or second pair of wings; these being of ample size are peculiarly folded, being bent at nearly right angles, so as to pack up in small compass beneath the elytra or wing-covers when the beetle is at rest. In some species the membranous wings are wanting, but the elytra are always present; although in this case, as they are never required to be expanded for flight, they are generally soldered together by a straight suture at the middle line. In ordinary cases the inner straight margins of the wing-covers are simply but accurately applied to each other.

The *Coleopterans* are of all the orders of insects the most numerous, and the best known. Their singular forms, the brilliant and agreeable colours which many of them present, the large size of some of the species, the solid consistence of their teguments, which renders their preservation easy, and the regular series of affinities traceable through several of the groups, all combine to render them objects of particular interest and attention.

The head supports two antennæ of various forms, but almost always consisting of eleven joints. They have two compound eyes, but no ocelli. The mouth is composed of six principal pieces; of which four, called the mandibulæ and maxillæ, move transversely in pairs, while the remaining two are fixed, and close the mouth vertically. The uppermost of the two vertical pieces is called the *labrum*; the lowermost is termed the *labium*, and is itself subdivided into the *mentum* and *lingua*, and together with the maxillæ, or the lowest of the vertical pieces, supports a pair of articulated processes, called *palpi* or *feelers*.

The anterior segment of the thorax, or manitrunk, supports the first pair of feet, and greatly surpasses in extent the two other segments which form the alitrunk. The abdomen is sessile, and united to the trunk by a great part of its breadth. It is externally composed of six or seven wings.

The *tarsi* vary as to the number of their joints, in some *Coleoptera* having but three, in others four, in others five; modifications upon which Latreille founds his primary division of the order. *See* PENTAMERA, TETRAMERA, TRIMERA.

The *Coleoptera* undergo a complete metamorphosis. The larva resembles a worm; the head is encased in a firm horny substance; the mouth is analogous in the number and functions of its parts to that of the perfect insects; it has also generally six feet, but some species have instead only simple tubercles. When perfect the larva generally burrows in the earth, and excavates an oval cell, within which it undergoes its change into an inactive pupa; this is generally of a whitish colour, with the wings and legs folded upon the breast. The habitation and manner of life of these insects varies much, both in their immature and perfect stages. The affinities of the *Coleoptera* to the *Orthoptera* are of a closer and more manifest nature than can be traced between the *Coleoptera* and any other order of the mandibulate insects. The genus *Forficula* forms the intervening link. It was formerly placed by Linnæus at the end of the *Coleoptera*, and was subsequently referred by Latreille to the order *Orthoptera*; but now constitutes the type of an order apart and intermediate to these two. The absence in some ants of the wings, sting, and ocelli, has led Mr. Macleay to suspect that these *Hymenoptera* make an approach to the *Coleoptera*. Mr. Kirby would place the *Strepsiptera* in juxtaposition with the *Coleoptera*, observing that the metamorphosis in the former "being different from that of *Orthoptera* and *Hemiptera*, and nearer to that of the *Coleoptera*, this seems its most natural station, considered as an Elytrophorous order."

COLEO'PTILUM. (Gr. κολεος, *a sheath*, and πτιλον, *a feather*.) A term sometimes applied to the young leaves of Monocotyledons, from the circumstance of their always being developed within a sheath, while those of Dicotyledons are always naked. This is, however, a mistake both in fact and theory.

CO'LEORHI'ZA. (Gr. κολεος, *a sheath*, and ῥιζα, *a root*.) A term invented by Mirbel to denote the sheath within which the radicle of monocotyledonous plants is enclosed.

CO'LIC. (Gr. κωλον, *the colon*; one of the large intestines, to the seat of which the principal pain is generally referred.) There are many varieties of this complaint, and it arises from various causes, and exhibits different symptoms. The general indications of cure are to evacuate the bowels by the least irritating means, and, when the lower intestines are loaded, by the use of glysters; opiates and etherial remedies may be resorted to to allay spasms, and warm bath and fomentations are often necessary. There is a peculiar disease called the *painters' colic* or *dry bellyache*, which appears to arise from the absorption of lead into the system, and which therefore commonly attacks plumbers, painters, and makers of white paint and other colours and preparations in which lead is used; the persons employed also in the lead mines and furnaces are subject to it. It is often named from certain places in which it is peculiarly prevalent; as Poictou, Devonshire colic, &c. It begins with restlessness and uneasiness about the stomach, nausea, and obstinate costiveness. There is general spasm of the bowels, often accompanied by great pain, which is somewhat relieved by pressure; and this circumstance enables us to distinguish the complaint in question from inflammation of the bowels; into which, however, it runs, if not timely relieved by opiates, emollient glysters, warm bath, and gentle aperients, especially castor oil when it will remain on the stomach, by which the spasm is allayed and the bowels evacuated of their hardened and irritating fœces. This is the *acute* state of the disease; but it often occurs in a *chronic* form, in which case pains and constipation of the bowels are followed by ocsacional delirium, epilepsy, paralysis, especially of the hands, and wasting away of the muscles. This disease terminates fatally if not timely relieved, and above all the patient should be cautiously removed from all contact with lead, and allowed fresh air and a nutritious but not stimulating diet.

COLLA'PSE. (Lat. collabor, *I shrink down*.) A wasting of the body; or a sudden and extreme depression of its strength and energies.

CO'LLAR. (Lat. collæ.) In Architecture, an horizontal piece of timber connecting two rafters.

COLLAR. In Ornithology, the coloured ring round the neck of birds. In Malacology, the thickened secreting margin of the mantle in the testaceous Gastropods.

COLLAR, signifies a peculiar badge worn round the neck by knights of different orders. It consists of a gold chain, enamelled, &c., to which is attached the badge of the order of knighthood; and it is worn at court chiefly on state occasions, which are thence called *collar days*.

COLLARI'NO. (Fr. collarin.) In Architecture, that part of the Tuscan and Roman Doric columns on the upper part of the shaft encircling them like a small collar. The more proper name is an astragal.

CO'LLECT (Lat. con, *together*, and lego, *I read*), signifies, as the derivation of the word implies, a prayer *read together with* other parts of the Church of England service, either usually or on a particular occasion.

COLLECTA'NEA, is applied, in Literature, to a selection of passages made from various authors, usually for the purpose of instruction.

COLLE'CTORS. In Botany, dense hairs covering the styles of some species of *Compositæ*, &c.: and acting as brushes to clear the pollen out of the cells of the anthers.

CO'LLEGE. (Lat. collegium.) According to the primary meaning of the word, any society or number of persons bound together by the same laws or customs (*Collegæ, colleagues*). Among the Romans not only societies invested with a character resembling that of modern corporations, enjoying certain political rights in common (as the colleges of augurs, pontifices, &c.), were termed Collegia; but bodies of men who appear to have had no bond of union except common employment (as the collegia opificum, or colleges of the different trades) were also thus designated. Hence has originated the erroneous notion that the guilds of modern Europe were derived from similar institutions among the ancients, by attributing to the last-mentioned collegia a corporate character, which it is not sufficiently proved that they possessed; although some of these bodies, as we learn from the fragments of the lawyer Gaius, did in effect hold common property, and had their affairs administered by by-laws of their own. In England many corporate bodies are termed Colleges; *e. g.* the colleges of phy-

sicians and surgeons, of heralds, &c. &c. A college, in the academical meaning of the word, signifies a society established for academic purposes under royal or private foundation, endowed with revenues, and subject to a private code of laws. Where such a society possesses within itself all the means of instruction and the rights and faculties which are incident to a university, the terms University and College are in effect convertible, and indiscriminately used. Thus, Trinity College, Dublin, affords a specimen of an institution called indiscriminately by either title. On the other hand, the universities of Oxford and Cambridge are composed of a number of colleges united together under the same discipline and government, and in which those powers peculiarly belonging to a university are wielded by one class of authorities, the functions of the colleges superintended by another. The Scottish universities, not being in the strict sense of the words endowed societies (*i. e.* not possessing a regular body of fellows and scholars receiving stipends), cannot be properly termed collegiate bodies.

The early history of colleges is somewhat obscure; although there can be no doubt that they were originally founded, in the various universities of the middle ages, with similar objects and from the same charitable motives. The first students at these universities assembled together under no common bond of union, except that of academic study and discipline, and lodged as suited their own convenience. Next, hostels or boarding houses were established (in the first instance, it is said, by the religious orders for students of their own fraternities), in which the scholars lodged together under certain superintendence. Charitable individuals afterwards endowed these hostels, for the purpose of providing poor scholars with free lodgings. Finally, to these endowments were added (by gifts or bequests) stipends for all or a certain number of the scholars frequenting these inns or hostels; and thus the foundation of a college was completed. The distinction of language arising from ancient usages is still preserved at Oxford, where societies endowed for the maintenance of fellows and scholars are termed Colleges,—societies unprovided with such endowments, Halls. But at Cambridge there is no distinction between Colleges and Halls. At the university of Paris fifteen colleges, or more, are said to have been founded in the 13th century; and the whole number, in the course of time, amounted to eighteen greater and about eighty lesser. But these institutions assumed a different shape from that which they took in England. The greater colleges became appropriated to particular faculties, or departments of a faculty. Thus, for example, the Sorbonne was the college of the theological faculty; and, in process of time, the lectures and disputations of most of the faculties became confined to the walls of those colleges which were exclusively devoted to them. Hence the university became, in fact, a collection of academies for instruction in particular subjects, and its corporate character for purposes of education vanished altogether as early as the 15th century. (See *Malden on the Origin of Universities*, and the authorities there cited.)

The name and institution of colleges were derived by the English universities, together with most of their other peculiarities, from Paris; but their history is very different. The colleges now subsisting in both these universities were constituted by royal or private munificence; either as original foundations, or (more commonly) by the endowment of formerly subsisting halls or hostels with stipends for students. They were all formed on the same principle, consisting of a head (variously termed master, principal, provost, &c.); of a body of higher graduates (generally termed fellows); and another of inferior graduates (scholars), who, according to the terms of the several foundations, were or were not eligible as a matter of right to the fellowships. The colleges were thus founded simply for the purpose of assisting scholars in their progress through the university, not for that of conferring instruction. All those of Catholic foundation, it must be added, were intended to supply the church with ministers; hence the still subsisting regulations prohibiting the marriages of fellows. In the course of time independent members, *i.e.* members not upon the foundation nor sharing in the endowments, were admitted to reside within the walls of the colleges; and the task of superintending, and finally of instructing them, was gradually transferred from the university authorities to those appointed by and resident within the colleges. And, by the present constitution of our national universities, the only powers retained by the university as such are of a general character, as of conferring degrees and other honours, &c. &c.; while the function of education for the purpose of qualifying for those degrees has entirely passed into the hands of the colleges of which that university is composed, every member of the university being now, by usage which has acquired the force of law, also member of some college or hall. And, with respect to discipline and government, the power is shared between the university, which through its vice-chancellor and proctors exercises a general superintendence; and the colleges, which by their own officers maintain order within their own walls. A college, therefore, in the sense in which the term is applied at Oxford and Cambridge, has a double character,—1. as an endowed society; 2. as a house of education. In the first sense, the college is composed of the head, fellows, and scholars. It is under the government of the original laws framed by its founder, with such variations as in some cases time has introduced; but alteration is always jealously watched. According to the tenure of these statutes, the head is either chosen by the fellows from among themselves, or in some instances appointed by the crown or other authority. The fellows, again (who are mostly, but not universally, graduates who have passed the lowest degree, that of Bachelor of Arts), and the scholars, who are admitted when under-graduates, are either chosen from particular localities, schools, &c. &c., according to the will of the founder, or elected according to merit after free competition between members of the college or of the university at large. Every college is finally under the superintendence of a visitor, generally some high ecclesiastical functionary. 2. As a place of education, the college receives within its walls not only fellows and scholars, but also (in the great majority of instances) independent members, limited in number only by the extent of the lodging which it can afford; it being usual at Oxford (although not at Cambridge) that every student on entering the university should not only belong to a college or hall, but reside within its walls. The under-graduate members of the college are under the superintendence of the tutors. These are, in general, resident fellows, appointed by the head to perform this office. In some colleges each tutor has under his special control a certain number of under-graduates; in others the tutors divide among them, not the students, but the different branches of instruction which are to be communicated. Such is a very general outline of the system of English colleges; but each of these foundations is exclusively governed by its own laws and usages, and no comprehensive description will apply without exception to all. Oxford has nineteen colleges and five halls; Cambridge seventeen colleges or halls. In both universities the oldest are supposed to have existed from the middle of the 13th century; the greater part were founded between that period and the Reformation, but a few are of Protestant foundation.

CO'LLEGE OF JUSTICE. In Scottish Law, a term applied to the supreme civil courts, composed of the lords of council and session; together with the advocates, clerks of session, clerks of the bills, writers to the signet, &c. *See* Session.

CO'LLET. *See* Collum.

COLLIMA'TION. (Lat. collimo, *I aim at.*) The *line* of collimation, in a telescope, is the line of sight, or the straight line which passes through the centre of the object glass and the intersection of the wires placed in its focus. The *error* of collimation is the difference between the actual line of sight and the position which that line ought to have in reference to the instrument.

COLLIMA'TOR. Captain Kater gave the name of *floating collimator* to an instrument invented by him for ascertaining the horizontal point. It consists of a small telescope, furnished with cross-wires in its focus, and fastened horizontally on a flat iron float, which is made to swim on mercury, and which of course, when left to itself, will always assume one and the same invariable inclination to the horizon. If the cross-wires of the collimator be illuminated by a lamp placed in the focus of its object glass, the rays from them will issue parallel, and consequently be in a fit state to be brought to a focus by the object glass of any other telescope, in which they will form an image as if they came from a celestial object in their direction, *i.e.* at an altitude equal to their inclination. By transferring, then, the collimator still floating on a vessel of mercury from one side of a circular instrument to the other, we are furnished with two *quasi-celestial* objects, at precisely equal altitudes, or opposite sides of the centre; and if these be observed in succession with the telescope of a circle, bringing its cross to bisect the image of the cross of the collimator, the difference of the two readings on the limb will be twice the zenith distance of either; whence the horizontal or zenith point is immediately determined. Another form of the collimator has the telescope placed vertically, whereby the zenith point is directly ascertained. (*Phil. Trans.* 1828; *Pearson's Practical Astronomy*, vol. ii.)

COLLI'QUATIVE. (Lat. colliqueo, *I melt.*) Excessive evacuations are so termed, which appear to melt down the strength and substance of the body.

COLLI'SION. (Lat. collisio, from collido, *I strike against.*) In Mechanics, the action of one body impinging against or striking another with a certain degree of force. In order to explain the phenomena which take place when two bodies in motion impinge against each other, we suppose the bodies either perfectly non-elastic, or perfectly elastic, and that they move in a medium which offers no resistance. As none of these suppositions have place

exactly in nature, the results deduced from them must in practice undergo certain modifications.

In the case of non-elastic bodies, let us suppose, first, that the body A strikes against another body B, which is either at rest or is moving in the same direction with A toward C, but with a less velocity.

The body B presents an obstacle to the motion of A; part of the force of A must therefore be expended in overcoming the obstacle, that is to say, in causing B to move with a velocity equal to its own. But when the quantity of motion necessary for this purpose has been communicated, B no longer opposes the motion of A; so that both bodies have the same velocity after the shock. Now, since a body cannot impart force to another without losing precisely an equal quantity itself, the sum of the forces, or *moments*, must remain the same after as before collision; but it has just been shown that the velocities of both bodies are the same after the shock; therefore (this momentum being measured bv the product of the mass into the velocity) the sum of the moments is distributed between the two bodies in the proportion of their masses, and the common velocity is found by dividing the sum of the moments before the impact by the sum of their masses.

Let us next consider the shock of two bodies moving in opposite directions. If the forces by which they are animated are equal, they will destroy each other at the instant of collision; if they are not equal, the greater will destroy the smaller, and the two bodies will then move in the direction of that whose moment was the greater, and the two moments will be equal to the difference of the moments before the impact. In this case also the velocity after the impact is the same for both bodies, and equal to the difference of the moments divided by the sum of the masses, and the remaining force is distributed between the two bodies in proportion to their respective masses.

In the case of elastic bodies, the results are modified by a new force being brought into action. Let an ivory ball A strike against another B advancing in the same direction but with a less velocity. The first effect of the collision is to produce a momentary union of the two balls, and to compress or flatten the impinging surfaces; the next is the effort of the bodies to recover their figure, and when the elasticity is perfect (as it is here supposed to be) the compressed surfaces are restored with a force exactly equal to that by which they were displaced. This restoring force, produced by the elasticity, is called the *recoil*, and its effect is to double precisely the effect that would be produced if the bodies were non-elastic. When the balls A and B come into closest union, they take a common velocity, A losing exactly as much as B gains. But in recovering their figure, the loss of A's velocity and the gain of B's velocity are each doubled. In order, therefore, to obtain the actual velocities of the impact, we may estimate the velocities that would be gained or lost by each if non-elastic, and add or subtract this to or from the common velocity they would have upon the same hypothesis.

If the masses of the two bodies are equal, their velocities are interchanged. If only one of the equal bodies be in motion, it will come to rest after the impact, and the other will move forward in the direction in which the first was moving, and with the same velocity; if they move in opposite directions, each will return in the contrary direction with the velocity the other had. Whether the bodies be equal or unequal, the difference of their velocities, or their relative velocity, will be the same in amount both before and after the impact.

A result of this theory, which at first sight appears paradoxical, is, that when several elastic bodies increasing in magnitude are arranged in the same straight line, touching each other, and one smaller than the least of them strikes against the least, each will in turn be reflected, and communicate to the succeeding one a greater quantity of motion than it has itself. This increase of momentum is greatest when the masses of the bodies increase in geometrical progression.

In all cases of collision the state of the centre of gravity, whether at rest or in motion, remains the same after the impact as before. If it was at rest, it remains in that state; and if it was in motion, it continues to move in the same direction and with the same velocity, notwithstanding the impact. This is the case both in respect of non-elastic and elastic bodies; and it is a constant law in whatever manner the bodies act on each other, and whatever be their respective natures. (For a full and elementary explanation of this subject, see *Maclaurin's Account of Newton's Principia.*)

CO'LLUM. (Lat. collum, *the neck.*) That part of the axis of a plant whence the stem and root diverge. In the beginning it is a space which there is no difficulty in distinguishing, so long as the embryo or young plant has not undergone any considerable change; but in the process of time it is externally obliterated, so as to become a mere matter of theory.

COLLUTORIUM. (Lat. colluo, *I wash*, and so, *the mouth.*) A lotion for rincing the mouth.

COLLY'RIUM. (Gr. κωλυω, *I check*, and ῥους, *a defluxion.*) Lotions intended to check inordinate discharges. The term is now exclusively applied to *eyewaters*.

CO'LOBUS. (Gr. κολοβος, *mutilated.*) A genus of long-tailed Quadrumanes, or monkeys; so called, because the fore hands are deficient in, and, as it were, mutilated of, a thumb. In this respect the *Colobi*, which are exclusively limited to the African continent, resemble the spider-monkeys (*Ateles*) of South America: but they have not a prehensile tail to compensate for the imperfection of the hands; their long caudal appendage is, on the contrary, terminated by a tuft of hairs. The *Colobi* differ also from the *Ateles* in having five molar teeth instead of six on each side of each jaw, and in having cheek-pouches.

CO'LOCYNTH. (Gr. κωλον, *the colon*, and κινεω, *I move.*) This term is applied in the Materia Medica to the pith of bitter apple, the fruit of the *Cucumis colocynthis*, which is violently purgative. It is imported dried, and generally peeled, from Turkey: it is rarely used alone; but one of the most valuable purgatives is the *compound extract of colocynth*, which is a combination of this drug with aloes, scammony, cardamum seeds, and soap.

COLOCY'NTIN. The bitter purging principle of the *colocynth*.

CO'LON. (Gr.) This name is given to the greater part of the large intestines: the colon passes upwards towards the liver, forming the *transverse arch* which descends upon the left side, forming its *sigmoid flexure;* entering the pelvis, it passes into the *rectum*.

COLON. In Grammar. *See* PUNCTUATION.

COLONNA'DE. (Lat. columna.) In Architecture, a series of columns placed at certain intervals, called intercolumniations, from each other, varying according to the rules of art and the order employed.

COLONEL. The commander of a regiment or battalion of troops: he is the highest in rank of *field officers*, and immediately subordinate to a general of division. The word is of uncertain origin. The *lieutenant-colonel* is immediately under the colonel, assisting in his duties, and being his substitute when required.

COLONY. (Gr. αποικια, Lat. colonia.) Colonies are establishments formed in foreign countries by bodies of men who voluntarily emigrate from, or are forcibly sent abroad by, their mother country. Various motives have, at different periods, led to the formation of colonies. Sometimes, as in the case of most of the Greek colonies of antiquity, they were formed by citizens driven from their native country by the violence of political factions; sometimes, as in the case of the Roman colonies, they were formed for the purpose of bridling subjugated provinces: the latter, indeed, were a species of camps or military stations, forming, as it were, the advanced posts of that mighty army which had its head-quarters at Rome: and sometimes, again, as in the case of the Phœnician colonies, and of most of those established in modern times, they have been formed for commercial purposes, or in the view of enriching the mother country, by opening new markets from which she might, if she chose, exclude foreigners.

The nature of the connection that has existed between colonies and their mother countries has been exceedingly various. Most of the Greek colonies being founded by private adventurers, who received no assistance from the government of the parent state, were really independent; the duty which they owed to their metropolis being such only as is due to kinsmen and friends, and not that due by subjects to their rulers. The Roman colonies, on the other hand, being founded by the state for an important political purpose, always maintained an intimate connection with, and dependence upon, Rome. They formed the great bulwarks of the empire; nor was the conquest of any province ever supposed to be completed till colonies had been established in it, and roads had rendered it accessible to the legions. The colonies established for commercial purposes have generally been subjected to such regulations as were deemed most for the advantage of the parent state. Their growth has thus in many instances been retarded; and they have been rendered less serviceable to their founders than they would have been had they been treated with greater liberality.

The very narrow limits within which this article must be compressed make it necessary that we should limit our statements to a few remarks, having more particular reference to those questions of colonial policy most interesting to the English reader.

The advantages supposed to result from that monopoly of the colony trade which all modern countries possessed of colonies have endeavoured to enforce, seem to be altogether imaginary. The ties of kindred, and the identity of language, customs, and manners, give the merchants of the mother country great advantages, and enable them, provided their goods be about as cheap as those of

others, to supply the colonial markets in preference to every one else. But all attempts to establish a monopoly in favour of the mother country, by prohibiting the importation of the produce of other nations into the colony, are necessarily either useless or prejudicial, not merely to its interests, but even to those of the mother country. If the latter can produce the articles required by the colony as cheap or cheaper than others, she will command the supply of the colonial markets, without any interference whatever; and if she cannot do this, unless by excluding the cheaper products of others, then it is plain the goods sent to the colony can only be produced by diverting a portion of the capital and industry of the mother country into comparatively disadvantageous channels, or into businesses in which she is excelled by others: it is plain, too, that no artificial monopolies can be maintained, except in the case of small and easily guarded colonies. The British merchants have at present the supply of by far the greater part of the manufactured goods required by our North American possessions; because the goods they send to them are generally cheaper than those sent there by other parties. But were competitors capable of underselling our merchants to appear in the field, they would have very little difficulty indeed in depriving them of these markets. Cheap goods are sure to make their way through every barrier; and the frontier of our North American colonies is so very extensive, and the impossibility of guarding it so obvious, that the smallest saving in point of expence would occasion the clandestine introduction of prohibited goods in unlimited quantities. In such a case custom-house enactments are good for nothing. All the tyrannical regulations and sanguinary punishments of Spain and Portugal were unable to prevent their transatlantic possessions being deluged with the prohibited commodities of Britain, France, and Germany. The ability to supply it with comparatively cheap goods is the only means by which it is possible to preserve any market. It is this that secures for us at this moment the same superiority in the markets of the United States that we possessed in them when they were our dependencies; and the moment we lose this advantage we shall not merely lose their market, but, with it, the markets of *all* our colonies. Nothing, therefore, can in reality be more futile than to found colonies, or to retain them in a state of unwilling dependency, in the view of monopolising their trade. If we can undersell others, we shall command their markets without any sort of interference; and if we cannot do this, the attempt to force upon them comparatively dear goods is sure to be defeated; or, if, unhappily, it should have a partial success, it would be injurious alike to the mother country and the colony.

A colony might be advantageous, and might contribute to increase the wealth of the mother country, if it yielded a greater revenue than was required for its government and defence: but this is rarely the case. Most colonies require a heavy outlay on their first foundation; and when they attain to any considerable importance, all attempts to make them contribute directly to increase the income of the mother country are very apt to excite discontent, and probably even rebellion: an unfortunate attempt of this sort led, in fact, to the American war. To obviate all chance of any such disastrous event occurring in future, we have distinctly renounced all pretensions to make our colonies contribute any thing, unless it be towards defraying the expense of their local government and militia. All the troops and squadrons required for their protection and security are furnished gratuitously by England; and, instead of deriving any revenue from our colonial possessions, they cost us *annually*, in time of peace, a direct outlay of about 2,500,000*l*. (*Official Account*, 18th of August, 1836.) In time of war, or when dissatisfaction prevails in any important colony, the direct outlay may be twice or three times as great.

A colony may, however, be advantageous in a pecuniary point of view, even when it costs the mother country a considerable direct outlay, provided it afford great facilities to individuals for making fortunes, with which to return to the mother country. A large sum is annually brought in this way into England from India; but our colonial possessions are, in this respect, of little advantage. Few, comparatively, of those individuals who acquire property in the N. American colonies return to England; and but few situations under the colonial government give the means of acquiring fortunes.

If a colony enjoy a natural monopoly of any product or article in extensive demand, it is supposed that, by laying a heavy duty on its exportation, a considerable advantage may be made to accrue to the mother country: but this does not really appear to be the case. Ceylon possesses a monopoly of the trade in cinnamon; but the enormously high duty (3*s*. per lb.) laid on the article when exported has restricted the demand for it to the narrowest limits, and reduced its culture, and the revenue derived from it, to a comparatively trifling amount. Most of our readers have no doubt heard of the immense profits made by the Dutch on spices, of which the possession of the Moluccas gave them the monopoly. But these high profits were wholly a consequence of the limitation of the quantity sold; and to prevent a fall of price by an increase of the supply brought to market, the Dutch occasionally destroyed a portion of the produce! There is no longer, however, so much even as the shadow of a doubt that they were heavy losers by this oppressive and short-sighted policy. The sales were confined to an amount hardly sufficient to employ the capital even of a single merchant; and the total sum realized by the government is not supposed to have amounted to the tenth part of what it would have risen to had the trade been left free, under a moderate duty.

When a nation derives the whole or any considerable portion of any important article from abroad, it is necessarily exposed, especially when the supply comes from one or a few foreign countries, to the risk of more or less inconvenience, from an interruption of the friendly intercourse subsisting with such countries. When such important articles are furnished by a colony, their supply is comparatively secure; and, in such cases, colonial possessions may be very valuable. At this moment any interruption of the trade with the United States would most probably, by interfering with the supply of raw cotton, be productive of the most calamitous results; and there can be no doubt that if the whole, or any considerable part of the supply of cotton, were derived from a colony, it would be an important advantage. This, however, is not the case. It is not improbable but that, at some future period, India may yield abundant supplies of cotton; but at present the cotton she sends to Europe is neither considerable in amount nor of good quality.

It was long supposed that our colonies in the West Indies were peculiarly valuable from their furnishing us with a secure and abundant supply of sugar, an article now become a necessary of life, and yielding a very large revenue. We doubt, however, whether there were ever any good foundation for such an opinion; but, whatever may have been the case formerly, there is none now. Sugar is not produced in one or a few countries only; but is a staple product of almost all intertropical regions; and it is now largely produced even in the northern parts of Europe. (*See* SUGAR.) So far, indeed, is it from being true that we are indebted to our West Indian colonies for abundant supplies of sugar, that the fact is nearly the reverse. Foreign sugar is, and has long been, excluded from our markets by oppressive discriminating duties; and were these repealed, and the duties on all sugars placed on the same level, it is exceedingly doubtful whether we should continue to derive any considerable portion of our supplies of sugar from our sugar colonies in the west.

Great stress is frequently laid on the advantage of colonies established in unoccupied countries, in affording a field for the ready and beneficial employment of the surplus or unemployed population that occasionally abounds in old settled and densely peopled countries; neither can there be a doubt that this is of very material importance. But it is pretty obvious that, having founded a colony, it is unnecessary to retain it in a state of dependence if it wish to become free, to realize the advantage referred to. Labour, in such colonies, is always in great demand, and a regard for their own interests always disposes the colonists to give every fair facility to the immigration of labourers. Notwithstanding the advantages occasionally held out by the British government to encourage emigration to our North American colonies, the great current of emigration has always been directed to the United States; and, even of the emigrants that sail from this country for Canada, scarcely a fourth part remain in the province, but immediately leave it for the contiguous states of the Union. It is idle, therefore, to attempt to excuse the policy of attempting to retain colonies in a state of reluctant dependence on the mother country, on pretence of their affording a profitable outlet for poor or unemployed persons. The interest of the settlers will keep this outlet open, and will secure every real advantage that could, in this respect, be derived from the most complete colonial domination.

We beg, however, that it may not be supposed, from any thing now stated, that we regard the foundation of colonies as inexpedient; on the contrary, their establishment has been highly advantageous to this as it has been to most old settled countries in all ages. It is not to their foundation, provided they be placed in proper situations and judiciously managed, but to the needless interference with their government, the trammels imposed on their industry, the prevention of their free intercourse with other people, and the attempt to govern them after they are able and determined to govern themselves, that we object. A nation that founds a colony in an unoccupied country, or in a country occupied only by savages, extends by so doing the empire of civilization to, it may be, an indefinite degree. Such colony not only forms a desirable outlet for the redundant or unemployed population of the mother country, but it forms a new and rapidly increasing market for its products and those of other

countries. No one can doubt that Europe has been signally benefited by the discovery and civilization of America; but the advantages thence arising, how great soever, would have been incomparably greater, but for the various impolitic regulations imposed by the mother states on their colonies. The British colonies, though fettered in various ways, enjoyed a much greater degree of freedom than those of any other country; and, in consequence their progress, both before and since the æra of their independence, has been proportionally rapid. The colonies of Spain, on the other hand, though occupying the finest provinces, had their progress thwarted by the blind jealousy and short-sighted rapacity of the mother country, and were kept as much as possible in a state of pupilage. The government was entirely administered by natives of Old Spain; the colonists were carefully excluded from every office of power and emolument; one colony was prohibited from trading with another; and had foreigners presumed to settle amongst them, they would have been liable to capital punishment. In consequence their progress was very slow; and when at length they succeeded in throwing off the galling yoke of the mother country, they became, from their inexperience in self-government, a prey to all sorts of disorders. It is very questionable whether her South American colonies were of the least service to Spain; and it is, at all events, certain that they have not conferred either on her or on other countries a tenth part of the benefit they would have done had they been treated with greater liberality, and permitted freely to avail themselves of all the advantages of their situation.

The American war seems to have decided, in so far as experience can decide any thing, the question as to the policy of retaining colonies in a state of dependency that are determined to govern themselves. No colonies were ever reckoned half so valuable as those which now form the republic of the United States; and it was generally supposed that their emancipation would be decisive of the fate of Britain,—that her sun would then set, and for ever! But have we really lost any thing by that event? Has our trade, our wealth, or our power been in any degree impaired by the independence of the United States? The reverse is distinctly and completely the fact. The notion that we could have continued for any length of time to retain such rapidly growing countries in a state of dependence, or that we could have been advantageously united in a federal union with vast regions situated in another hemisphere, is too wild and extravagant to require examination. But notwithstanding its independence we have continued, and will necessarily continue in all time to come, to reap all the advantage we can reasonably claim as founders of this mighty empire in the wilderness. Englishmen will necessarily always command a preference in the American markets. And while we are disencumbered of the impossible task and enormous expense attending the government and defence of all but boundless countries 3,000 miles distant, our intercourse with them grows with their growth; and we are as much benefited and enriched by them as we should have been had they continued in the same state of dependency as Australia or the Cape of Good Hope.

The previous remarks are not, of course, meant to apply to such dependencies as Malta or Gibraltar. These are not colonies, but naval stations, necessary for the accommodation of our ships of war and merchantmen, and serving also as secure depôts for our produce. Every commercial and maritime nation that takes a just view of its real interests will always take care to possess itself of some such strong-holds.

Neither are the previous remarks meant to apply to the conquest and occupation of foreign countries, in the view of increasing national opulence and power. Such policy may be either good or bad, according to the peculiar circumstances affecting each particular case. Our remarks apply only to colonies strictly so called; that is, to the case of foreign territories, peopled principally or wholly by emigrants, or by the descendants of emigrants from the mother country, and not held as a mere military station.

Sometimes, in order to carry on a trade with a colony, it is necessary to give its products peculiar advantages in the markets of the mother country; and consequently at the expense and to the prejudice of the consumers in the latter. We rather incline to think that no small portion of our trade with the West Indies is forced in this way; and that were the discriminating duties on foreign sugar abolished, we should derive a considerable part of our supplies from other quarters. But whatever may be the case with the West India trade, this, at all events, is the case with the Canada trade. It employs a large number of ships and seamen, and seems, to a superficial observer, highly valuable. In truth and reality, however, it is very much the reverse. Two thirds and more of this trade is forced and factitious; originating in the oppressive discriminating duty of 45*s*. a load imposed on timber from the north of Europe, over and above what is imposed on that brought from a British settlement in North America! This obliges us to resort to Canada, whence we import an inferior article at a comparatively high price. The disadvantages of this impolitic system are numerous and glaring. To a manufacturing country, having a great mercantile and warlike navy, timber is indispensable; and yet, instead of supplying ourselves with it where it may be found best and cheapest, we load the superior and cheaper article with an exorbitant duty; and thus do the most we can to make our houses and ships be built and our machinery constructed of what is inferior and dear! But the mischief does not stop here. By refusing to import the timber of the north of Europe, we proportionally limit the power of the Russians, Prussians, Swedes, and Norwegians to buy our manufactured goods; while, by forcing the importation of timber from Canada, we withdraw the attention of its inhabitants from the most profitable employment they can carry on, — that is, from the cultivation of the soil, — and make them waste their energies in comparatively disadvantageous pursuits! Such, either in a less or a greater degree, is the uniform result of all attempts to interfere with the natural order of things, and to force a trade, whether with a colony or a foreign country matters not, that would not otherwise be carried on.

But the existing state of our relations with Canada affords other matter for serious, and not very pleasant reflection: that colony is not, and never has been, of advantage to England. Were the duties on Canada timber reduced to the same level as those on Baltic timber, we question whether it would be found to possess a single article that could be advantageously exported to this country, or that we might not buy cheaper and better elsewhere. It no doubt affords an outlet for emigrants, and is in so far useful; but in all other respects its occupation has always been, and will most probably continue to be, productive of little except loss. And even as respects emigration, it is, as already explained, by no means clear that the field would be at all narrowed by Canada becoming independent, or connected with the United States.

But useless as Canada has been to England in time past, the connection with it will, in all probability, become much more onerous in time to come. We shall not stop to inquire whether the Canadians have good grounds for the dissatisfaction that prevails so generally amongst them. It is enough to know that it exists; and that nothing but the presence of a large British army is able to maintain our nominal ascendency in that province. While this state of things continues, the prosperity of the colony must be at a stand; emigration to it will cease or be greatly narrowed; and the distresses in which the settlers will be involved will give additional strength to the party wishing to break off the connection with the mother country. The people of Britain would do well to reflect dispassionately on the state of the Canadian question. There are not, perhaps, a dozen men of sense in the empire who are not ready to admit that in some ten or twenty years Canada will be independent, or be incorporated with the United States. But if so, what should be our policy in the mean time? Are we resolved to maintain an army of 10,000 or 15,000 men in Canada? — to expend, directly and indirectly, some three or four millions a year in preserving a mere nominal ascendency in a colony our connection with which is really a loss? If such be our determination, it may be doubted whether we have profited much by the dear-bought experience afforded by the American war. National pride may prevent our relinquishing this costly and barren dominion; but good sense, and the most obvious views of expediency, would seem to suggest the policy of voluntarily anticipating what there is every reason to think must in the end necessarily happen, and of providing for the independence of Canada under a system of friendly and mutually beneficial relations.

The explanation given by Dr. Smith in the *Wealth of Nations* (book iv. cap. 7.) of the causes of the rapid growth and prosperity of colonies founded in advantageous situations, though impugned by Sismondi (*Etudes sur l'Economie Politique*, ii. cap. "Colonies") and others, seems to be consistent alike with principle and historical evidence. When a colony is founded in an uninhabited or but thinly peopled district, each colonist gets a large extent of the best land; he has no rent, and but few if any taxes to pay; and being able to procure supplies of manufactured articles from the mother country, or one equally advanced, he applies all his energies to agriculture, which under the circumstances is most productive. The demand for labour in such colonies is very great; for the high rate of wages, combined with the cheapness of the land, speedily changes the labourers into landlords, who in their turn become the employers of fresh labourers. In consequence population and wealth advance with unusual rapidity; and in some instances, as in that of the United States, they have continued for a lengthened period to go on doubling every twenty or five and twenty years!

But in stating that the facility of obtaining supplies of fertile and unoccupied land is the principal cause of the rapid progress of new colonies, it is not meant to affirm that it is the only cause. An advantageous situation for the prosecution of commercial pursuits, and great superiority in navigation, may enable a colony to advance at its outset, though without any considerable extent of territory, with even more rapidity than if it enjoyed an unlimited command of fertile land. This seems to have been the principal cause of the speedy extension of the Greek colonies in antiquity. The most famous of these, as Syracuse and Agrigentum in Sicily, Tarentum and Locri in Italy, and Ephesus and Miletus in Asia Minor, were amongst the principal emporia of the ancient world. They were all sea-port towns; were founded in the most advantageous situations for carrying on an extensive commerce, and owed, in fact, their wealth and greatness mainly to trade and navigation. Owing, however, to the limited extent of their territorial acquisitions, a consequence partly of the difficulty of subduing the indigenous population, and partly of the neighbourhood of other colonies founded by rival states, their power rested on no very broad or solid foundation; so that the fall of the capital city and the annihilation of the state were all but synonymous.

The colonies founded in modern times have been placed under very different circumstances. The countries in which they were planted were either so very thinly inhabited as to be almost deserts, or they were occupied by a feeble and inferior race unable to oppose any effectual obstacle to the diffusion of the colonists; so that the latter easily spread themselves over a large extent of country, and have had in general more of an agricultural than of a commercial character. But while this has given them greater strength, it has not, after the difficulties attendant on their first establishment were got over, in any degree impeded their progress, but the contrary. The most flourishing of the colonies of antiquity will not bear to be compared in respect of rapidity of growth, magnitude and power, with the United States; and the slower progress of the Spanish and Portuguese colonies is not owing to the colonists having distributed themselves over a wide extent of country, but to the oppressive interference of the mother country with their domestic arrangements, and the vexatious restrictions laid on their intercourse with foreigners.

A very great degree of equality prevailed among the free settlers in Greek colonies; and in consequence the lands accquired by the colonists were distributed amongst them in nearly equal portions. But in modern times it is very different. Owing to the vast extent and almost desert state of the countries in which they have been principally planted, the poorest individuals have generally succeeded in acquiring slips of land; while the superior class of colonists, or those who had influence with the colonial government, or with that of the mother country, frequently succeeded in getting grants of vast tracts of land, not in the view of cultivating, but of holding them till in consequence of the increase of population in the vicinity they had acquired a considerable value. These large reserves, by interrupting the communications between different parts of the colony, and increasing the difficulty and cost of conveyance, have frequently proved not a little injurious to its interests. But there are various ways in which an abuse of this sort might be obviated; and perhaps the best would be to apportion the land according to the available capital of the settlers, it being stipulated that no individual should receive above a certain number of acres, and that it should revert back to the public unless certain improvements were effected upon it within a specified time after the grant was made.

But not satisfied with attempting to put down an abuse of this sort, we are now told that all the difficulties incident to colonization have originated in the too great dispersion of the colonists; and that to obviate them, and to ensure to all new colonies the acme of prosperity, we have merely to compel the colonists to keep close together by exacting a high price for the surrounding waste or unoccupied land; in other words, by making the colony as like an old settled country as possible! Perhaps such a crude project was hardly worth notice. If, on the one hand, the price set on the waste land were inconsiderable, it would not prevent the purchase of large tracts of land on speculation, and the entailing on the colony all the disadvantages that have resulted from the making of injudicious grants; and if, on the other hand, the price demanded for the land were pretty high, it would go far to oppose an insuperable obstacle to the progress of the colony. Rich men do not leave their native country to expose themselves to the inconveniences and hardships attending the establishment of new settlements in the wilderness. This, if it be done at all, must be done in time to come as in time past, by individuals in straitened circumstances, and anxious to improve their fortunes. But to exact a high or considerable price for land from such persons would, by sweeping away the whole or a considerable portion of their capital, deprive them of the means of clearing and cultivating the land, and proportionally retard their progress and that of the colony. The plan of letting lands by fine is admitted by every one who knows any thing of agriculture to be one of the worst that can be devised; and this colonization project is bottomed on the same principle, and will no doubt be as pernicious.

It is said that in consequence of the exaction of a price for the land, and the concentration of the colonists, their employments, being more combined and divided, will be prosecuted with a great deal more success than at present. All this, however, proceeds on the false and exploded assumption that the colonists are not, like other individuals, the best judges of what is for their own advantage. Dr. Smith says truly that it is the highest impertinence for kings and ministers to attempt to direct private people *how* they should employ their capitals. But it is, if possible, a still greater impertinence to attempt to direct them *where* they shall employ them. A regard to their own interest will draw people sufficiently together; and to enact regulations in the view of concentrating them still more, is in every respect as contradictory and absurd as it would be to set about increasing the public wealth by regulating the sort of employments to be carried on, and the countries with which, and the commodities in which, to deal.

We have already sufficiently explained the principal cause of the rapid progress made by some of the Greek colonies: it should, however, be borne in mind that these colonies had great numbers of slaves, who carried on most part of the more common employments. Hence, in Syracuse or Tarentum, every rich individual might have as many obsequious servants as he pleased, and all sorts of luxurious accommodations were to be had in the greatest profusion. But in those modern colonies where slavery is abolished, the different ranks and orders of men are more nearly assimilated, less by the depression of the rich than by the elevation of the poor. What is wanted in refinement and attention is far more than compensated by the wellbeing and comfort of the lower classes.

It is a part of this new project, on the supposed excellence of which much stress is laid, that the sums got by the sale of lands in the colony are to be expended in defraying the expense attending the conveyance thither of labourers. This is a species of bait held out to tempt capitalists to buy land, by making them believe that though land be artificially dear, labour will be artificially cheap, and that on the whole they will be very well off! This, however, is merely attempting to repair an injury done the capitalists, by inflicting a still more serious injury on the labourers. In a colony where a large portion of the capital is swallowed up in the purchase of land, the demand for labour must be comparatively limited; and this limited market is to be glutted by throwing upon it crowds of paupers transported gratis from England! We say crowds of paupers; for few labourers aware of the facts of the case, who can afford to pay for a passage to the United States, will voluntarily go to a colony where land is to be artificially raised to a high price, and labour artificially reduced. The whole scheme seems, in fact, to be little else than a tissue of delusions and contradictions, and it says little for the discernment of the public that it should have attracted any notice.

It is true that the Americans sell their unoccupied lands; but they sell the richest and finest lands in the valley of the Mississippi at less than a dollar an acre, whereas we exact 5*s*. an acre for the worst land at the antipodes, or in that *terra incognita* called Southern Australia! If these regulations be intended to divert the current of voluntary emigration from our own colonies to the United States, they do honour to the sagacity of those by whom they were contrived, and there is not a word to be said against them; but in all other respects they seem to be as impolitic and absurd as can well be imagined. (For further information on this important subject, see *St. Croix, de l'Etat et du Sort des Anciennes Colonies;* the art. "Colony" in the *Encyclopædia Britannica;* and *M'Culloch's Commercial Dictionary*, and Edition of the *Wealth of Nations.*)

CO'LOPHON. In Bibliography, the postcript contained in the last sheet of an early printed work (before the introduction of title-pages), containing the printer's name, date, &c., is so termed; from a fanciful allusion to a Greek satirical proverb, in which the people of Colophon, in Asia Minor, are reproached with being always the hindmost.

COLO'PHONITE. A variety of garnet of a *resinous* fracture.

COLO'PHONY. (Gr. Κολυφωνια, the city whence it was first brought.) The dark-coloured resin which remains after the distillation of oil of turpentine.

COLO'SSAL. (From Colossus, a very large statue at Rhodes.) In the Fine Arts, a term applied to any work of art remarkable for its extraordinary dimensions. It is, however, more applied to works in sculpture than in the other arts. It seems probable that colossal statues had their origin from the attempt to astonish by size at a period when the science of proportion and that of imi-

tation were in their infancy. Colossal statues of the divinities were common both in Asia and Egypt. By the description of the palace or temple attributed to Semiramis it abounded with colossal statues, among which was one of Jupiter forty feet in height. In Babylon we learn from Daniel that the palaces were filled with statues of an enormous size, and in the present day the ruins of India present us with statues of extraordinary dimensions. The Egyptians surpassed the Asiatics in these gigantic monuments, considering the beautiful finish they gave to such a hard material as granite. Sesostris, according to history, appears to have been the first who raised these colossal masses, the statues of himself and his wife, which he placed before the temple of Vulcan, having been thirty cubits in height. This example was imitated by his successors, as the ruins of Thebes sufficiently testify. The taste for colossal statues prevailed also among the Greeks. The statue of Apollo at Rhodes, executed by Chares, a disciple of Lysippus, has indeed given this species of art the name it bears; and the great Phidias contributed several works of this order. The colossus at Tarentum by Lysippe was no less than forty cubits in height; and the difficulty of removing it, rather than the moderation of the conqueror, prevented Fabius carrying it off with the Hercules from the same city. But the proposition made to Alexander of cutting Mount Athos into a statue, in one of whose hands a city was to be placed capable of holding ten thousand inhabitants, whilst in the other he was to hold a vessel pouring out the torrents from the mountain, exceeds all others in history. Before the time of the Romans colossal statues were frequently executed in Italy. The first monument of this nature set up in Rome was one placed in the capitol by Sp. Carvilius after his victory over the Samnites. This was succeeded in after times by many others, of which those now on Monte Cavallo, said to be of Castor and Pollux, are well known to most persons. In modern times the largest that has been erected is that of S. Carlo Boromeo at Arona near Milan. This gigantic statue is upwards of sixty feet in height.

COLOSSE'UM. *See* AMPHITHEATRE.

COLO'STRUM. The first milk after delivery. A mixture of turpentine with the yolk of egg.

CO'LOUR. (Lat. color.) In Painting, that quality of a body which affects our sensation in regard to its hue. *Local colours* are those which are natural to a particular object in a picture, and by which it is distinguished from other objects. *Neutral colours* are those in which the hue is broken by partaking of the reflected colours of the objects which surround them. *Positive colours* are those unbroken by such accidents as affect neutral colours.

CO'LUBER. A Linnæan genus of serpents, including all those in which the subcaudal scale-plates or scutæ are arranged in pairs. This extensive group is now subdivided into numerous subgenera.

CO'LUM. A term, now obsolete, denoting that part of the ovarium from which the ovula arise; commonly called the Placenta.

COLU'MBA. (Lat. columba, *a pigeon*.) A genus of birds which form the transition from the Passerine to the Gallinaceous orders. They fly well; live in a state of monogamy; build their nests in trees or in the crevices and fissures of rocks; and lay but few eggs at a time, generally two; their tail is composed of twelve quill-feathers: so far the Columbæ resemble the Passerine birds. But their beak is vaulted; the nostrils perforated in a broad membranous space, and covered with a cartilaginous scale, which even forms a bulge at the base of the bill; the sternum is deeply and doubly notched; a dilated crop is developed from both sides of the œsophagus; the stomach is a true gizzard; and the lower larynx has only a single pair of muscles: all these important modifications of structure indicate the close affinity of the Dove tribe to the Gallinaceous birds. And it may be further remarked, that although the pigeons lay but few eggs at each brood, they breed frequently, and at short intervals. The male assists his mate in the business of incubation and rearing of the young, which are at first supported by a milky secretion prepared from the glandular coat of the crop, and regurgitated, together with the macerated grain. The Linnæan genus is subdivided into numerous but unimportant subgenera, characterized by the greater or less length of the bill, and the proportions of the feet and tail.

COLU'MBA NOACHI. (Noah's Dove.) A small constellation in the southern hemisphere, near the hinder feet of Canis Major, formed by Halley.

COLUMBA'RIUM. (Lat.) In Architecture, a pigeonhouse or dovecote. From the similarity the arched and square-headed recesses in the walls of cemeteries, which were made to receive the cinerary urns, were also called Columbaria.

COLU'MBIA. A bitter crystalline principle, obtained from colomba root.

COLU'MBIUM. A metal discovered by Mr. Hatchett in 1801, in a mineral from Massachusets in North America. It has since been found in a Swedish mineral called tantalite, but its ores are extremely rare. It is acidifiable, and hence the peroxide has been termed *columbic acid*.

COLUMELLIA'CEÆ. (Columellia, one of the genera.) An obscure natural order of shrubby or arborescent Exogens, inhabiting Mexico and Peru; distinguished from *Jasminaceæ*, to which order they have been referred, by having an adherent ovary, a perigynous disk, undivided stigma, and inferior capsule with polyspermous cells. Of its true affinity little is known.

CO'LUMN. (Lat. columna.) In Architecture, a member of an order whose section through the axis is usually a frustum of an elongated parabola. It is circular on every height of its plan, and consists of a base, shaft or body, and a capital. It differs from a pilaster, which is square on the plan. The use of the column is to support the entablature. *See* ORDER.

CO'LURES. In Astronomy, two imaginary great circles of the celestial sphere intersecting in the poles of the world; one passing through the equinoctial points of Aries and Libra, and the other through the solstitial points of Cancer and Capricorn. For this reason the first is called the *equinoctial*, and the second the *solstitial* colure. The name Colure, derived from Gr. κολουρος (cauda truncus, *imperfect*), is supposed to have been given to those circles because a portion of them is always concealed from view under the horizon. But this is the case with every other meridional circle as well as the colures.

CO'LZA, OIL OF. The oil expressed from the seed of the *Brassica oleracea*, a species of cabbage. Colza oil is much used in France and Belgium for burning in lamps and other purposes.

CO'MA. (Gr. κομη, *hair*.) The assemblage of branches forming the head of a forest tree. Also used to denote bracts that are empty and terminate an inflorescence, as in *Salvia horminum*.

COMA. (Gr. κωμα, *a swoon*.) Lethargy, or unnatural drowsiness; whence the term *comatose*.

CO'MA BERENI'CES. (Literally *Berenice's hair*.) A constellation of the northern hemisphere, between the tail of the Lion and Bootes. *See* CONSTELLATION.

COMB, or COOMB. A measure of corn, commonly four Winchester bushels.

COMB, or COMBE, in the western counties of England, signifies a small valley. The same ancient word of Celtic derivation is used in Wales (cwm), and in the Alps between France and Piedmont (combe), in the same sense.

COMBINA'TION. (Lat. con, and binus, *double*.) In Algebra, signifies the disposition or arrangement of any number of objects or symbols in all possible ways. The two principal problems that occur in the theory of combination are the following: — 1st, Any number of things with the number in each combination being given; to find the number of combinations. 2d, To find the number of alterations which any number of quantities can undergo when combined in every possible variety of ways. In the solution of the first problem we have to consider that in combining things by pairs, two things, *a*, *b*, admit of one combination only, viz. *a b*; three things, *a*, *b*, *c*, admit of three, viz. *ab*, *ac*, *bc*; four admit of six, viz. *ab*, *ac*, *ad*, *bc*, *bd*, *cd*; five admit of ten, viz. *ab*, *ac*, *ad*, *ae*, *bc*, *bd*, *be*, *cd*, *ce*, *de*. Generally, if n denote the number of things, the formula which expresses the number of all their combinations by pairs is $\frac{n(n-1)}{1\cdot 2}$. Thus, if $n=5$, then $\frac{5\cdot 4}{1\cdot 2}=10$; if $n=6$, then $\frac{6\cdot 5}{1\cdot 2}=15$ is the number of combinations.

When the things are combined by *threes*, the number of combinations that can be made out of a given number n, is $\frac{n}{1}\times\frac{n-1}{2}\times\frac{n-2}{3}$. If combined by *fours*, the number of combinations is $\frac{n}{1}\times\frac{n-1}{2}\times\frac{n-2}{3}\times\frac{n-3}{4}$, and so on.

The number of combinations of all sorts that can be made of n things (that is, by first taking the things one at a time, then taking them by twos, then by threes, and so on) is 2^n-1. Thus, all the possible combinations or selections that can be made of three things are $2^3-1=7$, viz. *abc*, *ab*, *ac*, *bc*, *a*, *b*, *c*.

The second problem requires us to take into account not only the different combinations of the things themselves, but also the order of their arrangement. Admitting this element of variation,

Two things may be varied by pairs in four ways: thus, *aa*, *ab*, *ba*, *bb*.

Three quantities, taken by pairs, may be varied nine ways; thus, *aa*, *ab*, *ac*, *ba*, *ca*, *bb*, *bc*, *cb*, *cc*.

Generally the number of variations by pairs which can be made of n things is equal to n^2; when taken by threes, the number of variations is n^3; when by fours, the number of changes is n^4, and so on. Hence the whole number of changes in n things, taken by *twos*, by *threes*, by *fours*,

and so on to n, is the sum of the geometrical series $n + n^2 + n^3 + n^4 \ldots\ldots + n^n = \frac{n^n - 1}{n-1} \times n$. Thus, if $n=5$, the number of possible changes is $\frac{5^5-1}{4} \times 5 = 3905$; and if $n=24$ (the number of letters in the alphabet), the theorem gives 1391724288887252999425128493402200, a number consisting of 34 digits. *See* PERMUTATION.

COMBINA'TION. In Law, may take place for the performance of any unlawful act, and is punishable before such act is executed. But the word has been commonly used in a particular sense; viz. that of a combination among workmen to demand wages at a particular rate; which was an unlawful act prior to the 6 G. 4. c. 129. repealing former statutes. Workmen are now at perfect liberty to form such combinations; but penalties are enacted by the statute against such as use threats or violence towards those who refuse to join in them. And the offence of administering unlawful oaths (whether preparatory to a combination among workmen, or for any other purpose) remains unaffected by the statute.

Combinations to raise wages, or "strikes," have formed for the last fifty years the most embarrassing difficulties with which British manufacturers, and the labouring classes themselves, have had to contend; and it can scarcely be said that the repeal of the combination laws in 1824 has produced much effect either to encourage or diminish them. On this subject we shall make an extract from a note, or rather a dissertation on "wages of labour," in Mr. M'Culloch's Edition of *Smith's Wealth of Nations*, in which the tendency of combinations to fetter commercial operations is set forth with a brevity and perspicuity no where surpassed.

"The repeal of the act against voluntary combinations in 1824 was a just and a wise measure. If any number of persons choose to combine to refuse to work, except for a certain amount of wages, or for certain hours per day, or week, to forbid them would seem to be a most oppressive interference with one of the distinguishing privileges of free labourers. It was found too that practically the laws against such combinations were good for nothing, and that, instead of putting them down, they gave them a secret character, and made them be easily perverted to other and more objectionable objects. But when workmen have power to refuse to employ themselves on terms of which they disapprove, they have got *all*, in this respect, to which they are entitled. None of them have any right to dictate to their fellows; or to say that because they object to certain stipulations in the terms offered by such and such employers, no one else shall be allowed to accept them. A pretension of this sort strikes at the very foundations of society; and if tolerated might enable juntos of designing individuals to inflict irreparable injury, not only on the employers of labour, but on the manufactures of the country, and consequently on the lasting interests of the labouring class. We need not, however, be surprised to learn that this is what numbers of workmen in various places have attempted to do; and that combinations have been formed, not for the legitimate purpose of refusing to work except on certain conditions, but for preventing other workpeople who may disapprove of, or not choose to insist on, these conditions, accepting the terms offered by their employers. The measures taken to enforce this most unjustifiable pretension have in some instances been of a very obnoxious description, and have evinced the existence of a very dangerous spirit. Nothing should be omitted that may serve to root out and suppress combinations for such illegal ends. They are completely subversive of that security essential to the prosecution of all industrious undertakings; and are, at bottom, as hostile to the interests of those that enter into them as they are to the interests of every one else." (For further details on this subject, see *A. Smith*, Book i. chap. 8.; *the Parliamentary Debates of the Year* 1824; *Torrens on Wages and Combinations*, London, 1834; *Edinb. Review*, vol. 39. 59.)

CO'MBRETA'CEÆ. (Combretum, one of the genera.) A natural order of shrubby or arborescent Exogens, all living within the tropics, and placed indifferently in the vicinity of *Santalaceæ* and *Elæagnaceæ*, or of *Onagraceæ* and *Myrtaceæ*. They all possess an astringency, and some are employed in dyeing. Some are polypetalous, some apetalous. They are especially distinguished by their convolute embryo.

COMBU'STION. This term is generally applied to the phenomena exhibited by burning bodies, and which depend upon the rapid union of the *combustible* with the oxygen of the air. The evolution of heat and light which attends this process announces intense chemical action; and we consequently find that combustion is always attended by the production of new compounds. *See* HEAT.

CO'MEDY. (From the Greek words κώμη, *a village*, and ᾠδη, *a song*; because the original rude dialogues, intermixed with singing and dancing, out of which the early Greek comedy arose, were sung by rustic actors at village festivals.) A species of drama, of which the characteristics in modern usage are, that its incidents and language approach nearly to those of ordinary life; that the termination of its intrigue is happy; and that it is distinguished by greater length and greater complexity of plot from the lighter theatrical piece entitled a farce. The original Attic comedy was a burlesque tragedy in form, in substance a satire on individuals, and founded on political or other matters of public interest. The modern comedy is derived from the new comedy of the Greeks, of which Menander and Philemon were the principal authors, and which has been preserved to us through the Latin imitations of Plautus and Terence. *See* DRAMA.

CO'MET. (Gr. κομητης, from κομη, *hair*.) The name given to a numerous class of celestial bodies belonging to the solar system. The luminous point which shines with greater or less brilliancy at the centre of a comet is called its nucleus. The nucleus is generally surrounded by a *nebulosity*, or luminous aurora. The train of light, of greater or less extent, with which most comets are accompanied, is called the *tail*. Formerly this name was only applied to the luminous train when it fell behind the comet in its diurnal motion; if it preceded the comet, it was called the *beard*; but this distinction has disappeared in modern works on Astronomy.

The ancients gave the name of comet to every nebulous star or meteor which was observed to pass successively through different constellations. Modern astronomers apply the name, notwithstanding the etymology, to stars which have neither nebulosity nor tail. According to them, the distinctive characters of a comet are, 1st, that it possesses a proper motion; 2d, that it traverses space in a curve so elongated that in the distant parts of its orbit it ceases to be visible. The proper motion distinguishes comets from those new stars which occasionally appear, and become extinguished without changing their place in the sky. The elongated form of the orbit establishes a distinction equally marked between the comets and the planets.

Orbits of Comets. — Some of the ancient philosophers regarded comets as simple meteors, engendered in the atmosphere. In order, however, to be convinced that they occupy a far more remote situation, it is only necessary to compare simultaneous observations at very distant places on the earth. Tycho Brahe was the first who showed that their true place is in the planetary regions: since the time of Tycho, it has been discovered that they revolve about the sun according to regular laws, similar to those which govern the planetary motions; and that their orbits are very elongated ellipses, having the sun in one of their foci.

Comets are only visible during the short time they are near the perihelia of their orbits. But an elongated ellipse, and a parabola having the same summit and focus, only begin to diverge sensibly at a considerable distance from the common summit. In order, therefore, to represent the different positions of a comet during the short time it is visible, we may in general without any inconvenience substitute a parabola for an ellipse. If it happens that the orbit cannot be represented by a parabola, we conclude that the ellipse is not very elongated. Now, by means of three positions of a comet seen from the earth, all the elements of its parabolic orbit may be determined. These elements are, 1st, the line of the nodes; 2d, the inclination of the orbit to the plane of the ecliptic; 3d, the perihelion distance, or least distance of the comet from the sun, expressed in parts of the earth's semidiameter; 4th, the instant of the passage through the perihelion; 5th, the longitude of the perihelion. When these elements are known, the path of the comet is completely determined; and it is only necessary, in addition, to indicate the direction of the motion, that is to say, whether it is in the order of the signs, or the contrary.

The proper motion of all the planets is performed from west to east in the order of the signs; comets, on the other hand, appear to traverse the heavens in all directions indifferently. Of 129 comets whose orbits have been determined, there are 68 whose motion is direct, and 61 whose motion is retrograde, and their orbits intersect the ecliptic at all possible angles. Out of the whole number there are only three whose returns to the sun in successive revolutions have been verified by observation. These are, 1st, Halley's comet, of which the period is about seventy-five and a half years; 2d, Encke's, whose period is about three and one third years; and 3d, Biela's, which performs its revolution in six years and about eight months.

Halley's Comet. — Newton was the first who submitted the motion of a comet to calculation, and pointed out a method of determining its orbit from three of its observed positions. Halley applied Newton's method to a great number of comets, of which the positions had been observed; and on comparing the resulting elements, per-

ceived that the comet which appeared in 1682 moved nearly in the same orbit as one which had been observed in 1607, and another which had been observed by Apian in 1531. As the interval between these successive apparitions was nearly the same, namely, about seventy-six years, the identity of the three comets appeared to Halley to be established, and he accordingly predicted its return in 1759. Clairaut, a celebrated French mathematician, computed the time at which it would arrive at its perihelion; and his results were confirmed by observation, the comet actually passing its perihelion within about a month of the time predicted.

The computation of the comet's return to its perihelion is a work of great difficulty and labour; for in consequence of the attractions of the larger planets, the path of the comet is considerably changed at each revolution, and all these changes or *perturbations*, as they are called, must be computed from the theory of gravitation.

The reappearance of this comet in 1835 was expected with great interest. Its perturbations in the previous revolution were calculated by Damoisean and Pontecoulant in France, and by Rosenberger in Germany, and the time of its perihelion passage fixed for the month of November in that year. Damoisean's calculation gave the 4th, Pontecoulant's the 7th, and Rosenberger's the 3d of the month. The comet, true to its appointed laws, became visible about the end of August, in the part of the heavens predicted; and it appears from the comparison of the numerous observations that were made of it, to have actually passed its perihelion on the 16th of November. The position of its orbit was such that it could scarcely be seen in Europe after the passage, on account of its proximity to the horizon; but it was then caught by the astronomers of the southern hemisphere, and continued to be observed by Sir John Herschel at the Cape of Good Hope till the end of March, 1836, when its increasing distance from the earth rendered it invisible. For some weeks it continued visible to the naked eye, but its splendour was not very remarkable.

Encke's Comet.—Two other comets have more recently been identified as having been seen in preceding revolutions about the sun. One of these is called Encke's comet, from Professor Encke of Berlin, who first computed its elliptic elements. Its orbit is very elongated, the eccentricity being nearly = ·845, and inclined to the ecliptic in an angle of about $13^\circ\ 22\frac{1}{3}'$. The period of its revolution is 1207 days, or about 3 and 1-3d years. Though this comet was not recognized as periodic till 1819, it had frequently been observed in previous revolutions—in 1789, 1795, 1801, and 1805. From the ellipse calculated by Encke, its return was predicted in 1822. On this occasion it was invisible in Europe, but was observed at Paramatta in New South Wales. In the subsequent returns of 1825, 1828, and 1832, it was observed in the principal observatories both in the northern and southern hemispheres. In comparing the intervals between the successive returns to its perihelion, it is found that the period of this comet is continually diminishing. This is exactly the effect that would be produced if it moved through a resisting medium; for the resistance, by diminishing the actual velocity, diminishes the centrifugal force, in consequence of which the solar attraction preponderates, and the comet is drawn nearer to the sun, and completes its revolution in a shorter time. Accordingly, as there appears no other way of accounting for the observed acceleration, it seems now to be the general opinion of astronomers that an ethereal medium pervades the regions of space, of sufficient density to affect the motions of comets, though so rare as to offer no sensible resistance to the denser masses of the planets, whose periods of revolution have continued exactly the same since the epoch of the first astronomical observations. If this medium really exists, the comet must ultimately fall into the sun, unless it is dissipated altogether; an event which seems not improbable, from the observed fact of its having been less conspicuous at each reappearance.

Biela's Comet.—The third periodic comet at present known was discovered by Biela, an Austrian officer then residing at Prague, in February, 1826; and by M. Gambart of Marseilles in April of the same year. It has been identified with comets observed in 1772, 1789, 1795, 1846, &c. It performs its revolution in 2461 days, in an ellipse inclined to the ecliptic, in an angle of $13^\circ\ 33'\ 15''$, having an eccentricity of 0·74701, its greater semi-axis being 3·56705. Its last apparition took place, in accordance with calculation, in 1839; and its next return will be in 1846. It is a small comet, having no tail, and presenting no appearance of a solid nucleus, but only a slight increasing density towards the centre; and small stars were seen through it. Its orbit, by a singular coincidence, nearly intersects that of the earth; and had the earth, at the time of the comet's passage in 1832, been a month in advance of its actual place, it would have passed through or very near the comet.

Effects of the Action of the Planets on the Orbits of Comets.—Comets in passing near the larger planets are drawn aside from their paths, and have their orbits sometimes entirely changed. In June, 1770, a comet was discovered by Messier; and as soon as three observations had been obtained, the elements of its parabolic orbit were determined. The comet continued visible for a long time, and it was found that the parabolic elements could not be made by any combination to represent the observations. It followed, therefore, that the orbit could not be a parabola. Lexell undertook the computation of an elliptic orbit, and found, in fact, that the comet was describing an ellipse, of which the greater axis was only equal to three times the diameter of the terrestrial orbit, and would consequently complete its revolution in about five years and a half. He accordingly predicted its return at the end of that period; nevertheless, the comet did not appear at the expected time, and, though very conspicuous in 1770, has never been seen since. On examining the catalogues, no trace was found of a comet describing the same orbit having been seen before. The question, therefore, occurred, in what manner was this mysterious appearance and disappearance to be explained? The solution was found in the disturbing influence of Jupiter. On submitting to calculation the action of this planet on the comet, it was found, in the first place, that in the year 1767, before the comet had approached Jupiter, the elliptic orbit which it described corresponded to a revolution, not of five, but of fifty years; and in the second place, it was found that in 1779, when getting beyond the sphere of attraction of the same planet, the orbit in which it then moved could only be described in twenty years. Previously to 1767 it moved in so wide an orbit that it could not be seen from the earth: the attraction of Jupiter threw it into the orbit in which it was observed by Messier. On a second approach to Jupiter, it was again deflected from its path, and thrown into an orbit in which it was invisible as at first.

Physical Nature of Comets.—Notwithstanding the attention which has been given to the observation of comets whenever they make their appearance, nothing whatever is known of their physical constitution; nor has any rational or even plausible explanation been offered of the voluminous appendage denominated the tail. The following remarks of Sir John Herschel on this subject are extremely interesting.

"The smaller comets, such as are visible only in telescopes, or with difficulty by the naked eye, and which are by far the most numerous, offer very frequently no appearance of a tail, and appear only as round or somewhat oval vaporous masses, more dense towards the centre; where, however, they appear to have no distinct nucleus, or any thing which seems entitled to be considered as a solid body. Stars of the smallest magnitudes remain distinctly visible, though covered by what appears to be the densest portion of their substance; although the same stars would be completely obliterated by a moderate fog, extending only a few yards from the surface of the earth. Whenever powerful telescopes have been turned on these bodies, they have not failed to dispel the illusion which attributes solidity to that more condensed part of the head which appears to the naked eye as a nucleus; though it is true that in some a very minute stellar point *has* been seen, indicating the existence of a solid body.

"It is in all probability to the feeble coercion of the elastic power of their gaseous parts by the gravitation of so small a central mass, that we must attribute this extraordinary development of the atmosphere of comets. If the earth, retaining its present size, were reduced by any internal change (as by hollowing out its central parts) to one thousandth part of its actual mass, its coercive power over the atmosphere would be reduced in the same proportion, and in consequence the latter would expand to a thousand times its actual bulk; and indeed much more, owing to the still further diminution of gravity by the recess of the upper parts from the centre.

"That the luminous part of a comet is something in the nature of a smoke, fog, or cloud, suspended in a transparent atmosphere, is evident from a fact which has been often noticed; viz. that the portion of the tail, where it comes up to and surrounds the head, is yet separated from it by an interval less luminous, as if sustained and kept off from contact by a transparent stratum, as we often see one layer of clouds laid over another, with a considerable space between. These, and most of the other facts observed in the history of comets, appear to indicate that the structure of a comet, as seen in section in the direction of its length, must be that of a hollow envelope, of a parabolic form, enclosing near its vertex the nucleus and head, something as is represented in the annexed figure.

This would account for the apparent division of the tail into two lateral branches, the envelope being oblique to the line of sight at its borders, and therefore a greater depth of illuminated matter being there exposed to the eye. In all probability, however, they admit great varieties of structure, and among them may very possibly be

bodies of widely different physical constitution." (*Astronomy; Cabinet Cyclopædia*, p. 304.)

From the same authority we extract the following statement respecting the actual dimensions of some of the most conspicuous comets: — "The tail of the great comet of 1680, immediately after its perihelion passage, was found by Newton to have been no less than 20,000,000 of leagues in length, and to have occupied only two days in its emission from the comet's body! — a decisive proof this of its being darted forth by some active force, the origin of which, to judge from the direction of the tail, must be sought in the sun itself. Its greatest length amounted to 41,000,000 leagues, a length much exceeding the whole interval between the sun and the earth. The tail of the comet of 1769 extended 16,000,000 leagues, and that of the great comet of 1811, 36,000,000. The portion of the head of this last comprised within the transparent atmospheric envelope which separated it from the tail was 180,000 leagues in diameter. It is hardly conceivable that matter once projected to such enormous distances should ever be collected again by the feeble attraction of such a body as a comet — a consideration which accounts for the rapid progressive diminution of the tails of such as have been frequently observed." (Ibid. p. 311.)

It is extremely probable that the comets are merely collections of gaseous matter, of which a part may be dissipated in space at every revolution; but further observations are wanted to make this hypothesis certain. In 1682 Halley's comet appeared as round and clear as Jupiter; in 1759 it was not visible to the naked eye; in 1836 it was again sufficiently visible, but it was then in a much more favourable position than in 1759.

In former times comets were regarded as preternatural appearances, betokening the displeasure of the superior powers, and accordingly viewed with the terror and apprehension naturally excited by harbingers of indefinite and unavoidable calamity. Since they have been discovered to be component parts of the solar system, their appearance excites no other interest than that which astronomers feel to determine their orbits, and to deduce from their physical aspects such conclusions as they are calculated to afford relative to the constitution of the universe.

COMETA'RIUM. An astronomical toy, intended to represent the motion of a comet about the sun. Any instrument capable of describing an elongated ellipse may be called a *cometarium*. *See* ELLIPTIC COMPASSES.

COMI'TIA. In Ancient History, the assemblies of the Roman people, which were of three kinds, distinguished by the epithets *Curiata*, *Centuriata*, and *Tributa*.

1. The Comitia Curiata were the assemblies of the patrician houses or *populus;* and in these, before the plebeians attained political importance, was vested the supreme power of the state. The name *Curiata* was given because the people voted *in curiæ*, each curia giving a single vote representing the sentiments of the majority of the members composing it; which was the manner in which the tribes and centuries also gave their suffrages in their respective comitia. After the institution of the Comitia Centuriata, the functions of the curiata were nearly confined to the election of certain priests, and passing a law to confirm the dignities imposed by the people.

2. The Comitia Centuriata were the assemblies of the whole Roman people, including patricians, clients, and plebeians, in which they voted by centuries. By the constitution of the centuries, these comitia were chiefly in the hands of the plebeians, and so served originally as a counterpoise to the powers of the comitia curiata, for which purpose they were first instituted by the lawgiver king Servius Tullius. These comitia quickly obtained the chief importance, and public matters of the greatest moment were transacted in them; as the elections of consuls, prætors, and censors, and the passing laws and trials for high treason.

3. The Comitia Tributa were the assemblies of the plebeian tribes. They were first instituted after the expulsion of the kings; and in them were transacted matters pertaining to the plebeians alone, as the election of their tribunes and ædiles.

CO'MMA. (Gr.) In Music, the smallest of all the subdivisions, being about the ninth part of a tone.

COMMA. In Grammar. *See* PUNCTUATION.

COMMA'NDER. In the Navy, otherwise called master, an officer next in rank above lieutenant, corresponding with major in the army.

COMMANDER-IN-CHIEF. The officer in whom is vested the supreme command of all the land forces of the British Empire. This officer is appointed by the ministry of the day, whose confidence he is supposed to enjoy, and he is assisted in the discharge of his duties by several subordinate officers, such as the adjutant-general, the quartermaster-general, &c. (see these terms), who are each at the head of a particular department.

COMMA'NDERY, or PRECEPTORY. According to the usages of some orders of Knights, a district attached to a manor or chief messuage under the control of a member of the order, who receives the income of that district arising from the estates of the order, taking out of it his own pension, and accounting for the rest.

COMMELINA'CEÆ. (Commelina, one of the genera.) A natural order of herbaceous Endogens, chiefly inhabiting the East and West Indies. Brown remarks that the order greatly differs from *Juncaceæ* both in habit and structure, and agrees better with *Restiaceæ*, having but little affinity with Palms; and Agardh adds, that it agrees with *Orchidaceæ* in the structure of the stamens and seeds, but in what respect he does not state. The species are very often mere weeds, but occasionally are beautiful flowering plants. A common example is the *Tradescantia virginica*.

COMME'NDAM. (Lat.) A term of the Canon Law. A person to whom custody of a void ecclesiastical benefice is committed by the superior, without the profits appertaining to it, was said to hold the benefice *in commendam*, i. e. *entrusted to his care;* but by various devices the restriction on the receipt of profits was evaded, and the holding benefices in commendam became a mode of enjoying pluralities. By the English law, no one can hold in commendam without license from the crown. An ordinary case is where clergymen promoted to bishoprics with insufficient revenues are allowed in this manner to retain the profits of livings.

COMME'NSURABLE. Quantities, in Geometry, are said to be commensurable when they have some common measure or divisor which divides each of them without leaving a remainder. Thus a yard and a furlong are commensurable magnitudes, because a foot is a measure or aliquot part of each of them, being contained in the yard three times, and in the furlong 660 times. Fractional numbers and surds are also said to be commensurable when they have a common measure of the same kind as themselves. Thus $\frac{2}{3}$ and $\frac{3}{4}$ are commensurable, being each divisible by $\frac{1}{6}$; and so are $2\sqrt{2}$ and $3\sqrt{2}$, being each measured by $\sqrt{2}$.

CO'MMENTARY. (Derived from the Latin verb comminiscor, *I call to mind.*) In Literature, a word used in different significations: — 1. In the same sense with memoirs, as a short narrative of particular events and occurrences, composed by an actor or spectator of those events with the professed object of calling back the circumstances to his own mind; *e. g.* the Commentaries of Cæsar. 2. Critical observations on the text or contents of a book. These are either in the form of detached notes, containing remarks on particular passages; or they are embodied in what is termed a running commentary, or series of remarks written and printed in a connected form.

CO'MMERCE (from *commutatio mercium*), is the exchange of one sort of produce or service for some other sort of produce or service.

Exchanges of this description have their rise in the nature of man and the circumstances under which he is placed, and their origin is coeval with the formation of society. The varying powers and dispositions of different individuals dispose them to engage in preference in particular occupations; and in the end every one finds it for his advantage to confine himself wholly or principally to some one employment, and to barter or exchange such portions of his produce as exceed his own demand, for such portions of the peculiar produce of others as he is desirous to obtain and they are disposed to part with. The division and combination of employments is carried to some extent in the rudest societies, and it is carried to a very great extent in those that are most improved; but to whatever extent it may be carried, commerce must be equally advanced. The division of employments could not exist without commerce, nor commerce without the division of employments: they mutually act and react upon each other. Every new subdivision of employments occasions a greater extension of commerce; and the latter cannot be extended without contributing to the better division and combination of the former.

In rude societies, the principal business of commerce, or the exchange of one sort of commodities for some other sort, is carried on by those who produce them. Individuals having more of any article than is required for their own use endeavour to find out others in want of it, and who at the same time possess something that they would like to have. But the difficulties and inconveniences inseparable from a commercial intercourse carried on in this way are so obvious as hardly to require being pointed out. Were there no merchants or dealers, a farmer, for example, who had a quantity of wheat or wool to dispose of, would be obliged to seek out those who wanted these commodities, and to sell them in such portions as might suit them; and having done this, he would next be forced to send to, perhaps, twenty different and distant places, before he succeeded in supplying himself with the various articles he might wish to buy. His attention would thus be perpetually diverted from the business of his farm; and while the difficulty of exchanging his own produce for that of others would prevent him from acquiring a

taste for improved accommodations, it would tempt him to endeavour to supply most things that were essential by his own labour and that of his family; so that the division of employments would be confined within the narrowest limits. The wish to obviate such inconveniences has given rise to a distinct mercantile class. Without employing themselves in any sort of production, merchants or dealers render the greatest assistance to the producers: they collect and distribute all sorts of commodities; they buy of the farmers and manufacturers the things they have to sell; and bringing together every variety of useful and desirable articles in shops and warehouses, individuals are able, without difficulty or loss of time, to supply themselves with whatever they want. Continuity is in consequence given to all the operations of industry; for, as every one knows beforehand where he may dispose to the best advantage of all that he has to sell, and obtain all that he wishes to buy, an uninterrupted motion is given to the plough and the loom. Satisfied that they will have no difficulty about finding merchants for their produce, agriculturists and manufacturers think only how they may improve and perfect their respective businesses. Their attention, no longer dissipated upon a variety of objects, is fixed upon one only. It becomes the object of every individual to find out machines and processes for facilitating the separate task in which he is engaged; and while the progress of invention is thus immeasurably accelerated, those who carry on particular businesses acquire that peculiar dexterity and *sleight of hand* so astonishing to those who live in places where the division of labour is but imperfectly established. Facility of exchange is, in truth, the vivifying principle, the very soul of industry; and no interruption is ever given to it without producing the most ruinous consequences.

The merchants, or dealers, collect their goods in different places in the least expensive manner; and by carrying them in large quantities at a time they can afford to supply their customers at a cheaper rate than the latter could supply themselves. Not only, therefore, do they, by enabling every employment to be carried on without interruption, and the divisions of labour to be perfected, add prodigiously to the powers of industry, and, by consequence, to the wealth of the community, but they also promote the convenience of every one, and reduce the cost of merchandising to the lowest limit. According as commerce is extended, each particular business becomes better understood, better cultivated, and carried on in the best and cheapest method: where it is far advanced, the whole society is firmly linked together; every man is indebted to every other man for a portion of his necessaries conveniences, and enjoyments; every thing is mutual, and reciprocal; and a large country becomes in effect, from the intimate correspondence kept up through the medium of the mercantile class, like a large city.

The annihilation of the class of traders would deprive society of all these advantages. The difficulties that would then be experienced in selling and buying would oblige every one to attempt, in so far as possible, directly to supply his own wants; the division of employments would be contracted on all sides, and Great Britain would gradually relapse into a state little, if at all, superior to its state at the Norman conquest.

The celebrated Italian economist, the Count di Verri, has defined commerce to be the conveyance of commodities from place to place (*trasporto delle mercanzie da un luogo a luogo*). This definition has been adopted by M. Say, who contends that commerce does not consist in exchanges, but in bringing commodities within reach of the consumers (*il consiste essentiellement à placer un produit à la portée de ses consommateurs*). But this is plainly to confound the means with the end; the preparations for an exchange with the exchange itself. The conveyance of commodities from place to place is necessary to enable commerce to be carried on; but unless they be conveyed in the view of being sold or exchanged for other commodities, and unless that exchange actually take place, there is no room or ground for considering the conveyance in the light of a commercial operation. It is obvious, too, that though the Count di Verri's definition were not erroneous in this respect, it is not sufficiently comprehensive. Suppose that a hat manufactory is established in Regent Street, and that a shop is attached to it, where the hats are sold; no one doubts that those employed in this shop are engaged in a commercial undertaking, and yet they have nothing to do with the carriage of commodities. Whatever, therefore, may be the particular sort of commerce carried on, whether the commodities have been brought from a distance or produced on the spot, its object and end is an exchange; when this end is not attained, no act of commerce can be said to have taken place.

The erroneous definition of commerce which M. Say has adopted has hindered him from rightly appreciating its influence. "In commerce," says he, "there is a genuine production, because there is a modification productive of utility and value. The merchant, after buying a commodity at its current price, sells it again at its current price; but the last price is greater than the former, because the merchant has brought the commodity into a situation which has really augmented its price, and the society is enriched by this augmentation." (*Cours d'Economie Politique*, t. ii. p. 213.) But though this be true, it is not the whole truth, nor even the greater part of it. Suppose that a hat-maker and a shoe-maker live in contiguous houses; if the one exchange his hats for the other's shoes society will not certainly gain much by the change in the locality of the commodities, but it will notwithstanding be materially benefited by the transaction; for, in consequence of the exchange, each tradesman will be able to confine himself to his own business: the hat-maker will not be obliged to waste his time in clumsy attempts to make his own shoes, nor will the shoe-maker be compelled to make his own hat. It is in this that the *peculiar* advantage of commerce consists. What an individual gives for anything is, speaking generally, the fair equivalent of what he gets. But the facility of exchanging allows every one, as has been already seen, to apply his entire time and energies to some one department; and in this way occasions the production of an incomparably greater quantity of all sorts of wealth than it would otherwise be possible to produce.

The mercantile class has been divided into two leading classes, — the wholesale dealers and the retail dealers. This division, like the divisions in other employments, has grown out of a sense of its utility. The wholesale merchants buy the goods at first hand of the producers; but instead of disposing of them to the consumers, they generally sell them to the retailers or shopkeepers, by whom they are retailed or distributed to the public in such quantities and in such a way as is most suitable for them. The interest of all parties is consulted by this division. Had the wholesale dealers attempted also to retail their goods, they could not have given that undivided attention to any part of their business so necessary to ensure its success. A retailer should be constantly at his shop; not merely that he may attend to the orders daily sent to him, but that he may learn all that transpires with respect to the situation of his customers, their wants, and their circumstances. But wholesale dealers being obliged to attend to what is going on in different and distant quarters, cannot give this minute attention to what happens in their immediate vicinity; and though they could, the capital required to carry on a wholesale business would not be sufficient for that purpose, were the business of retailing joined to it. Were there only one class of merchants, the capital and the number of individuals employed in commercial undertakings would not probably be less than at present; but the merchant, being obliged to apply himself principally to one department, would have to leave the chief share of the other to servants; a change which, as every one knows, would be productive of the most mischievous consequences.

There can, therefore, be no doubt that the separation in question has been highly advantageous. The classes of merchants, like those of artificers, are mutually serviceable to each other and to the public. Without this subdivision, commerce would have been impeded in its operations; particular branches of it would have been comparatively neglected; nor would any branch have been carried on with the same economy and attention with which all are now conducted.

In a highly civilized country like Great Britain, the trade in every commodity in considerable demand, as corn, sugar, tea, timber, &c., affords employment for a separate class of traders. But for all purposes of general inquiry, it is sufficient to consider commerce under three heads, viz.:—1. The Home trade, or that carried on between individuals of the same country; 2. Foreign trade, or that carried on between individuals of different countries; and, 3. The Colony trade, or that carried on between the inhabitants of any particular country and its colonists. We subjoin a few remarks upon each of these heads.

1. *Home Trade.* — It has been already seen that the varying capacities and dispositions of different individuals occasion the introduction of a division of employments, and the practice of exchange or barter. But the external circumstances under which different individuals are placed vary still more than their natural powers or tastes. One set inhabit a rich fertile plain, suitable for the growth of corn and other culmiferous crops. Another set inhabit a mountainous district, the soil of which is comparatively sterile, but which is well fitted for rearing cattle; another set are planted upon the margin of a river, or arm of the sea, abounding in every facility for carrying on the business of fishing; and so on. Now it is so obvious, that though the individuals belonging to any particular district had not established a division of labour amongst themselves, it would be highly for their advantage to establish one with those occupying other districts, the productions of which are materially different. When the inhabitants of Newcastle apply themselves principally to the coal trade, those of Essex to the raising of wheat, and those of the highlands of Scotland to the

raising of cattle and wool, each set avail themselves, in carrying on their employments, of the peculiar powers of production conferred by Providence on the districts they occupy; and by exchanging such portions of their produce as exceed their own consumption, for the surplus articles raised by others, their wealth and that of every one else, is immeasurably increased. It is in this *territorial division of labour*, as it has been happily designated by Colonel Torrens, that the main advantage of commerce consists. In commercial countries, each individual may not only enter at pleasure, on such pursuits as he deems most advantageous, but the entire population of districts and provinces are enabled to turn their energies into those channels in which they are sure to receive the greatest assistance from natural powers. Suppose England were divided into separate parishes, or even counties, surrounded respectively by Bishop Berkeley's wall of brass, and having no intercourse with each other, in what a miserable situation would we be! Instead of 1,500,000, London could not under such circumstances contain 15,000 inhabitants; and these would be exposed to numberless privations of which we have not the slightest idea. Unless the territorial division of labour were carried to some extent, the division of employments amongst individuals occupying the same district, could be but very imperfectly established, and would be of comparatively little use. It is only when one is able both to gratify his taste and to avail himself of the varying capacities of production given to different districts that the benefits of commerce can be fully appreciated, and that it becomes the most copious source of wealth as well as the most powerful engine of civilisation.

"With the benefits of commerce," says an eloquent writer, "or a ready exchange of commodities, every individual is enabled to avail himself to the utmost of the peculiar advantage of his place; to work on the peculiar materials with which nature has furnished him; to humour his genius or disposition, and betake himself to the task in which he is peculiarly qualified to succeed. The inhabitant of the mountain may betake himself to the culture of his woods, and the manufacture of his timber, the owner of pasture lands may betake himself to the care of his herds; the owner of the clay pit to the manufacture of his pottery; and the husbandman to the culture of his fields, or the rearing of his cattle; and any one commodity, however it may form but a small part in the whole accommodations of human life, may, under the facilities of commerce, find a market in which it may be exchanged for what will procure any other part, or the whole; so that the owner of the clay pit, or the industrious potter, without producing any one article immediately fit to supply his own necessities, may obtain the possession of all that he wants. And commerce in which it appears that commodities are merely exchanged, and nothing produced, is nevertheless, in its effects, very productive; because it ministers an encouragement and facility to every artist in multiplying the productions of his own art, thus adding greatly to the mass of wealth in the world, in being the occasion that much is produced."—(*Ferguson's Principles of Moral and Political Science*, vol. ii. p. 424.)

II. *Foreign Trade.*—The trade carried on between individuals of different countries is founded on precisely the same circumstances—the differences of soil, climate, and productions, on which is founded the trade between different districts of the same country. One country, like one district, is peculiarly fitted for the growth of corn; another for the cultivation of the grape; a third abounds in minerals; a fourth has inexhaustible forests; and so forth:—

> Hic segetes, illic veniunt felicius uvæ,
> Arborei fetus alibi, atque injussa virescunt
> Gramina. Nonne vides, croceos ut Tmolus odores,
> India mittit ebur, molles sua thura Sabæi?
> At Chalybes nudi ferrum, virosaque Pontus
> Castorea, Eliadum palmas Epiros equarum?
> Continuo has leges æternaque fœdera certis
> Imposuit natura locis.—*Georg.* lib. i. lin. 54.

Providence, by thus distributing the various articles suitable for the accommodation and comfort of man in different countries, has evidently provided for their mutual intercourse. In this respect, indeed, foreign trade is of far more importance than the home trade. There is infinitely less difference between the products of the various districts of the most extensive country, than there is between the products of different and distant countries; and the establishment of a territorial division of labour amongst the latter must therefore be proportionally advantageous.

"As the same country is rendered richer by the trade of one province with another; as its labour becomes thus infinitely more divided, and more productive than it could otherwise have been; and as the mutual interchange of all those commodities which one province has and another wants multiplies the comforts and accommodation of the whole, and the country becomes thus, in a wonderful degree, more opulent and more happy; so the same beautiful train of consequences is observable in the world at large,—that vast empire, of which the different kingdoms may be regarded as the provinces. In this magnificent empire, one province is favourable to the production of one species of produce, and another province to another. By their mutual intercourse, mankind are enabled to distribute their labour as best fits the genius of each particular country and people. The industry of the whole is thus rendered incomparably more productive; and every species of necessary, useful, and agreeable accommodation is obtained in much greater abundance, and with infinitely less expense."—(*Mills's Commerce Defended*, p. 38.)

But to enable the advantages of foreign commerce to be rightly appreciated, it will be proper to consider it under the following heads:—viz. 1. Its influence in supplying us with useful and desirable articles, of which we should otherwise be wholly destitute; 2. Its influence in multiplying and cheapening the peculiar productions of our own country; 3. Its influence in making us acquainted with foreign discoveries and inventions, and in exciting invention by means of competition and example; and, 4. Its indirect influence upon industry, by increasing the sources of enjoyment.

1. With respect to the first of these influences, or the effect of commerce in furnishing every people with commodities not otherwise attainable, it is too obvious and striking to require any lengthened illustrations. Great Britain is as abundantly supplied with native products as most countries; and yet any one who reflects for a moment on the nature and variety of the articles we import from abroad, must be satisfied that we are indebted to trade for a very large part of our superior accommodations. Tea, sugar, coffee, wine, and spices; silk and cotton, the materials of our most extensive manufactures; gold and silver; and an endless variety of other highly important articles, are sent to us by foreigners. And were the importation put an end to, what a prodigious deduction would be made, not from our comforts and enjoyments merely, but also from our means of supporting and employing labourers! If foreign commerce did nothing more than supply us with so many new products, it would be very difficult to overrate its value and importance.

2. But such is the beneficent influence of commerce, that while it supplies an endless variety of new productions, it multiplies and cheapens those that are peculiar to every country. It does this, by enabling each separate people to employ themselves, in preference, in those departments in which they enjoy some natural or acquired advantage, and by opening the markets of the world to their productions. When the demand for a commodity is confined to a particular country, as soon as it is supplied improvement is at a stand. The subdivision and combination of employments is, in fact, always dependent upon and regulated by the extent of the market. Dr. Smith has shown, that by making a proper distribution of labour among ten workmen, in a pin manufactory, 48,000 pins might be produced in a day; and since his time the number has been nearly doubled. But had the demand not been sufficient to take off this quantity of pins, the divisions and improvements in question could not have been made; and the price of pins would in consequence have been comparatively high. This principle holds universally. The most important manufacture carried on in Great Britain — that of cotton — is entirely the result of commerce. Supposing, however, that cotton wool had been a native product, we could never have made such astonishing advances in the manufacture had we been denied access to foreign markets. Notwithstanding the splendid discoveries in the machinery, and the perfection to which every department of the trade has been brought, the vast extent of the market has prevented its being glutted, and has stimulated our manufacturers and artizans to persevere with unabated ardour in the career of improvement. Our cotton mills have been constructed, not that they might supply the limited demand of Great Britain, but that they might supply the demand of the whole world. And in consequence of the extraordinary subdivision of labour, and the scope given to the employment and improvement of machinery by the unlimited extent of the market, the price of cottons has been reduced to less, probably, than a fourth part of what it would have been had they met with no outlet in foreign countries. The hardware, woollen, leather, and other manufactures, exhibit similar results. The access their products have had to other markets has led to important improvements in their production; so that, as was previously stated, commerce not only supplies us with a vast variety of new and desirable articles, but it also cheapens the staple productions of the country, and renders them more easily attainable by the great mass of people.

3. The influence of commerce in making the people of each country acquainted with foreign inventions and discoveries, and in stimulating ingenuity by bringing them into competition with strangers, is obvious and powerful. It distributes the gifts of science and art, as well as those of nature. It is the great engine by which the blessings of civilization are diffused throughout the world, the intercourse to which it gives rise making every one

acquainted with the processes carried on and the inventions made in the remotest corners of the globe. Were any considerable improvement made in any important art either in China or Peru, it would be very speedily understood and practised in England. It is no longer possible to monopolize an invention. The intimate communication that now exists amongst nations renders any important discovery, wherever it may be made, a common benefit. The ingenious machine invented by Mr. Whitney, of the United States, for separating cotton wool from the pod, has been quite as advantageous to us as to the Americans; and the inventions of Watt and Arkwright have added to the comforts of the inhabitants of Siberia and Brazil, as well as of England. The genuine commercial spirit is destructive of all sorts of monopolies. It enables every separate country to profit by the peculiar natural powers and acquired skill of all the others; while, on the other hand, it communicates to them whatever advantages it may enjoy. Every nation is thus intimately associated with its neighbours. Their products, their arts, and their sciences, are reciprocally communicated; and the emulation that is thus excited and kept up forces routine to give place to invention, and inspires every people with zeal to undertake, and perseverance to overcome, the most formidable tasks. It is not possible to form any accurate notions as to what would have been our state at this moment, had we been confined within our own little world, and deprived of all intercourse with foreigners. We know, however, that the most important arts, such as printing, glass-making, paper-making, &c., have been imported from abroad. No doubt we *might* have invented some of these ourselves; but there is not the shadow of a ground for supposing that we should have invented them all; and without foreign example and competition, we could hardly have carried any of them beyond the merest rudiments.

4. The influence of commerce upon industry, by its increasing the number of desirable articles, though not quite so obvious, perhaps, as the influences already specified, is not less powerful and salutary. Industry is in no respect different from the other virtues, and it were idle to expect it should be strongly manifested where it does not bring along with it a corresponding reward. In the early stages of society, before artificial wants have been introduced, and men are satisfied if they can avert the attacks of hunger, and procure an inadequate defence against the cold, industry is confined within the narrowest limits; and provided the mildness of the climate renders clothing and lodging of little importance, and the earth spontaneously pours forth an abundant supply of fruits, the inhabitants are immersed in sloth, and seem to place their highest enjoyment in being free from occupation. Sir William Temple, Mr. Hume, and some other sagacious inquirers into the progress of society have been struck with this circumstance, and have justly remarked that those nations that have laboured under the greatest national disadvantages have made the most rapid advances in industry.

But in civilized and commercial societies, new products and new modes of enjoyment, brought from abroad, or invented at home, stimulate the inhabitants to continued exertions. Their acquired tastes and the wants which civilization introduces, and custom and example render universal, become infinitely more numerous, and as urgent as the tastes or wants of those that are less advanced. The passion for luxuries, conveniencies, and enjoyments, when once excited, becomes quite illimitable. The gratification of one desire leads immediately to the formation of another. "The natural flights of the human mind are not from pleasure to pleasure, but from hope to hope." The happiness of a civilized nation is not placed in indolence or enjoyment, but in continued exertion; in devising new contrivances to overcome new difficulties; in extending still further the boundaries of science, and increasing their command over luxuries and enjoyments. The remark of the Abbe Mably is as true as it is forcibly expressed:—"*N'est on que riche? On veut être grand. N'est on que grand? On veut être riche. Est on et riche et grand? On veut être-plus riche et plus grand encore.*" (*Œuvres*, t. iv. p. 76.)

Without commerce this progress would never be realized. The commodities possessed by particular nations are but few, and may be attained with comparatively little labour. Generally speaking, a man may easily supply himself with corn, cloth, and beer; and if the utmost exertions of ingenuity and the most laborious efforts of industry could only furnish additional quantities of those articles, they would very soon cease to be made. Men do not practise industry and economy for their own sakes, but for the advantages that result from them; and the more, consequently, that these advantages are multiplied, that is, the greater the variety of wants they are made to supply, and of gratifications they are made to command, the greater will be the energy displayed in their prosecution. "*Le travail de la faim,*" as Raynal has well observed, "*et toujours borné comme elle; mais le travail de l'ambition croît avec ce vice* (*vertu?*) *même.*"

And hence the true way to render a people industrious is to endeavour to inspire them with a taste for the luxuries and enjoyments of civilized life; and this will be always most easily done by giving every facility to the cultivation of foreign commerce. The number of new articles, or, in other words, of new motives to stimulate, and new products with which to reward the patient hand of industry, is then prodigiously augmented. The home producers exert themselves to increase their supplies of disposable articles, that they may exchange them for those of other countries and climates; and the merchant, finding a ready demand for such articles, is stimulated to import a greater variety, to find out cheaper markets, and thus constantly to apply new incentives to the vanity and ambition, and consequently to the industry of his customers. Every power of the mind and body is thus called into action; and the passion for foreign commodities—a passion which some shallow moralists have ignorantly censured—becomes one of the most efficient causes of industry, wealth, and civilization.

IV. *Colony Trade.*—For some remarks on this head, the reader is referred to the article COLONIES.

Principle and Influence of Restrictions on Commerce.—The commercial intercourse carried on between the inhabitants of different districts of the same country, and those of different countries, is founded on the principle which prompts each member of the same family, or each inhabitant of the same village, to apply himself to some one business. It would therefore seem that that *freedom* of commerce which is universally admitted to be productive of the most beneficial consequences when established between the occupants of different districts of the same country must be equally beneficial when established between those of different countries. It appears to be generally believed, that to occasion a commercial intercourse, nothing more is necessary than to remove such legal or physical obstacles as may interpose to prevent it. But this is not by any means enough. A of Yorkshire does not sell to or buy from B of Kent, merely because there is nothing to hinder him from doing so; he must further believe that his interest will be promoted by the transaction: unless he do this, the utmost facility of exchanging will be offered to him in vain; nor will the finest roads or the speediest conveyances occasion the least intercourse. We neither buy nor sell for the mere pleasure of the thing. We do so only when we believe it will be a means of promoting some end, of procuring some peculiar advantage for ourselves that we could not so easily procure in any other way. If any one supposed he could better attain his object in entering upon a commercial transaction with some particular individual by entering upon a similar transaction with some one else, or by any other means, he would most certainly decline engaging in it. We may, and often do, make a false estimate of what is for our advantage; but its promotion is the mainspring of our actions; and it is it, and it only, that we have in view when we buy of a particular individual, or resort to a particular market, in preference to others.

Unless therefore it could be satisfactorily established that princes and rulers have a better understanding of what has a tendency to promote the wealth and industry of their subjects than themselves, it is difficult to see on what ground any restriction on the freedom of commerce is to be vindicated. The person who buys French wine or Polish corn, does so only that he may benefit himself: and the fair presumption is that he does what is right. Human reason is, no doubt, limited and fallible; we are often swayed by prejudice, and are apt to be deceived by appearances. Still, however, it is certain that the desire to promote our own purposes contributes far more than any thing else to render us clear-sighted and sagacious. "*Nul sentiment dans l'homme,*" says M. Say, "*ne tient son intelligence eveillée autant que l'interêt personnel. Il donne de l'esprit aux plus simples.*" The principle that individuals are, speaking generally, the best judges of what is most beneficial for themselves, is universally admitted to be the only one that can be safely acted upon. No writer of authority has latterly ventured to maintain the exploded and untenable doctrine, that governments may advantageously interfere to regulate the pursuits of their subjects. It is their duty to preserve order, to prevent one from injuring another; to maintain, in short, the equal rights and privileges of all. But it is not possible for them to go one step further, without receding from the principle of non-interference, and laying themselves open to the charge of acting partially by some, and unjustly by others.

"The statesman," says Dr. Smith, "who should attempt to direct private people in what manner they ought to employ their capitals, would not only load himself with a most unnecessary attention, but assume an authority which could safely be trusted not only to no single person, but to no council or senate whatever, and which would nowhere be so dangerous as in the hands of a man who had folly and presumption enough to fancy himself fit to exercise it." (*Wealth of Nations*, p. 200.)

In every discussion as to any point of public economy,

it is essential to bear in mind that the legislature abandons its duty, or rather acts in direct opposition to it, the moment it begins to legislate in the view of promoting the interest of particular classes. The question never ought to be, whether any proposed measure or regulation has a tendency to benefit agriculturists, manufacturers, or merchants; but whether its tendency be to benefit the public. Certain individuals or classes may be benefited by what is prejudicial to others; but it would be a contradiction to contend that a system of policy which enriches A by impoverishing B can be publicly advantageous; and it is upon this latter consideration that the attention of the legislature should always be fixed. Whatever has any tendency to increase the security of property, to perfect the divisions of labour, to stimulate industry and ingenuity, and to increase the wealth and comforts of *all* classes, deserves the encouragement of government. But when it goes further, and interferes to prohibit individuals from carrying on certain branches of trade that others may be promoted, it arrogates to itself that authority the assumption of which is so justly censured by Smith. Such prohibition is, in fact, quite subversive of the right of private property; for that right is violated, not merely when a man is unjustly deprived of any part of his fortune, but also when he is prevented from disposing of it in any way, not hurtful to others, he may think fit.

It does not therefore appear, considering this question on general grounds, that there is so much as the shadow of a foundation for those commercial restrictions that make so prominent a figure in the policy of all modern nations. If it could be shown that statesmen and ministers were the best judges of the means by which those subject to their authority might improve their condition, the case would be different. But no such pretension is set up, and, if it were, it would be universally scouted. We may safely leave the conduct of individuals to be determined by their own prudence and sagacity. They act under the most serious responsibility; and we have the best attainable security, the plain and obvious interest of the parties, that they will, in the peculiar circumstances under which they are placed, follow that course which is most advantageous for themselves, or, in other words, for the community. All systems of policy that would regulate the pursuits of private persons according to the views of government must be arbitrary and violent in their nature, and any attempt to act upon them could not fail to be productive of the most mischievous consequences. A wise government will confine its efforts to the maintenance of that order of things which nature has established. It will not mix itself up with the affairs of its subjects, but will leave them to pursue their own interest in their own way; to bring their industry and capital into the freest competition with those of others; and will interpose only when they swerve from the rules of justice. Freedom and security are all that is necessary to stimulate industry, and to insure the most rapid advancement in the career of improvement.

We cannot, however, feel any surprise that these principles should have been so widely departed from, and that commerce, and indeed most sorts of industry, should be everywhere subjected to restrictions and regulations. They originated in a comparatively unenlightened age, before the genuine sources of public wealth and the limits of proper interference on the part of governments had been explored and defined. The fallacies on which most of them are founded, however obvious they may now seem, were not speedily or easily detected; and, after their hollowness has been exposed, the return to a better system is a work of extreme difficulty. Every regulation affecting the employment of capital and industry, though always injurious to the public, is, for the most part, productive of advantage to a greater or smaller number of individuals. The moment that any change is proposed, these persons lay before government the most exaggerated representations of the injury that would result from the abolition or modification of the regulation; and not satisfied with this, they most commonly enlist a portion of the press into their service, and availing themselves of all the aid that sophistry and ingenuity can supply, labour to make the public believe that the regulation complained of is a national benefit, and that they are interested in its support! This device has very often been attended with the most complete success; and it is to this circumstance, more than any thing else, that the tenacity with which erroneous theories in commerce are supported is to be ascribed, and that sophisms, that have been again and again exposed, are put forward anew with as much seeming confidence as if they had never been questioned.

All the great branches of industry carried on in every country depend on peculiarities of soil or climate, or on the genius of the people, and not on custom-house regulations. What should we have to fear from the abolition of all prohibitions? We export the produce of every one of our principal manufactures, as cotton, wool, iron, leather, &c., to every market of the world; so that the possibility of our being injured by the admission of similar articles from abroad is quite out of the question. Admitting, however, that the abandonment of the protective system might force a few thousand workmen to abandon their employments, it is material to observe that *equivalent new ones* would, in consequence, be opened to receive them, and that the aggregate demand for their services would not be in any degree diminished. Suppose that, under a system of free trade, we imported a part of the silks and linens we now manufacture at home; it is quite clear, inasmuch as neither the French nor Germans would send us their commodities gratis, that we should have to give them an equal amount of British commodities in exchange: so that such of our artificers as had been engaged in the silk and linen manufactures, and were thrown out of them, would, in future, obtain employment in the production of the articles that must be exported as equivalents to the foreigner. It is idle, therefore, to pretend that the repeal or modification of a restrictive regulation can ever be a means of diminishing the demand for labour. We may, by giving additional freedom to commerce, change the *species of labour* in demand, and make it be employed more profitably, but we cannot lessen its quantity. Should our imports this year amount to ten or twenty millions more than they did last year, we shall, it is certain, have to pay them by exporting an equally increased amount of our peculiar products. And therefore if *exportation* be desirable, and the most ardent admirers of the restrictive system admit it to be such, *importation* must also be desirable, for the two are indissolubly connected; and to separate them, even in imagination, infers a total ignorance of the most obvious principles. Commerce, whether carried on between individuals of the same or of different countries, is founded on a fair principle of reciprocity; buying and selling are in it what action and reaction are in physics, *equal and contrary*. Those who will not buy from others render it impossible for others to buy from them. Every sale implies an equal purchase, and every purchase an equal sale. Hence *to prohibit buying is exactly the same thing, in effect, as to prohibit selling*. No merchant would ever export a single bale of goods were he prevented from importing a greater value in its stead. But it is impossible he can do this if foreign commodities be excluded. In whatever degree, therefore, an unrestricted trade might lead us to receive commodities from other countries, in the same degree it would render them customers for our commodities, would promote our manufactures, and extend our trade. To suppose that commerce may be too free, is to suppose that labour may be turned into too productive channels, that the objects of demand may be too much multiplied and their price too much reduced; it is like supposing that our agriculture may be too much improved, and our crops rendered too luxuriant.

It is often affirmed, though we believe without the least foundation for the statement, that had it not been for restrictions on importation, several manufactures that now furnish employment for a considerable population would most probably never have existed amongst us. But supposing this statement to be admitted, it would not form any valid objection to the principle now laid down. It is quite as much for the advantage of communities as of single families to respect the principle of the division of labour. The interests of every people will always be best promoted by addicting themselves, in preference, to those branches of industry in which they have a superiority over others; for it is by this means only they can ever fully avail themselves of their peculiar facilities of production, or employ themselves and their capital most beneficially.

When importation from abroad is restricted, that some new or incipient manufacture may be promoted, government assumes, though perhaps unconsciously, that it knows better than its subjects what is the most profitable line for them to engage in. Never was there an assumption more entirely unfounded. Individuals are always on the alert to find out what are the most advantageous businesses in which to embark; and though they sometimes, no doubt, form erroneous conclusions, the chances are ten to one in favour of their being right. Were it otherwise the number of well-advised and prosperous undertakings entered upon in all tolerably well-governed countries would not, as is the case, infinitely exceed those of a contrary description. But though it were different, the interference of government would not certainly abate the evil. However well intended, all attempts to introduce or extend some particular business cannot fail of being productive of immediate injury to others; and, should the object ever be realized, it would most probably not be found to be a national benefit, but the reverse. If, instead of directly producing linens, a manufacturer finds it more profitable to produce cottons or hardware, and to exchange these with the Germans for linen, how ridiculous would it be to attempt to promote the public interests by shutting out foreign linens, and compelling them to be produced at home! It is not disputed that the linen manufacture might be somewhat promoted by such a measure; but it admits of demonstration that other and more advanta-

geous businesses would sustain a corresponding depression. Governments may depend upon the fact, that their subjects are incomparably better informed with respect to these matters than they can ever be. It is not possible for them, do what they will, to interfere to encourage one set of producers, without at the same time, and by the same act, proportionally discouraging some other set. Their obvious duty is, therefore, to abstain from all interference with the legitimate pursuits of individuals. To the clamourers for protection they may always answer, that they would be happy to meet their wishes, provided they could do so without injuring others but that that being impossible, they feel themselves bound not to interfere, but to allow every one to reap the profit or abide the loss of the speculations into which he may enter.

We have not entered in this article into any investigations with respect to that great class of exchanges which consist in the rendering of labour or services for money or commodities. The laws by which they are governed may be more appropriately stated under the head LABOUR. It is sufficient here to observe, that prohibitions are to the full as injurious and inconsistent when applied to this description of exchanges as to the exchange of commodities.

Our object in this article has merely been to lay before the reader a brief view of the principles that govern commercial transactions, and of the mode in which commerce contributes to increase private and public opulence. To have entered into a detail of the various ways in which commerce may be facilitated, would have engaged us in discussions that would have added too much to the length of this article; and the reader is, therefore, referred for information on these points to the articles BANKS, COLONIES, EXCHANGE, MONEY, ROADS, WEIGHTS AND MEASURES, &c.

We subjoin some tables, derived from official sources, illustrative of the nature and extent of the commerce of Great Britain during the last few years: —

I. An Account of the Real or Declared Value of the principal Articles of British and Irish Produce and Manufacture exported in 1838.

Articles.	Declared Value, 1838.
	L.
Coals and Culm - -	484,305
Cotton Manufactures - - -	16,700,468
Yarn - - -	7,430,582
Earthenware - - -	670,985
Glass - - -	376,524
Hardwares and Cutlery - -	1,507,478
Linen Manufactures - -	2,919,719
Yarn - - - -	655,699
Metals; viz. Iron and Steel - -	2,530,903
Copper and Brass - -	1,226,258
Lead -	156,150
Tin, in Bars, &c. - -	103,230
Tin Plates - -	434,749
Salt - - - -	223,372
Silk Manufactures - - -	778,031
Sugar, Refined - - -	550,506
Wool, Sheep's or Lambs' - -	432,067
Woollen Manufactures - -	5,792,156
Yarn - - -	365,657
Total of the above Articles - -	43,338,839

II. Account of the Real or Declared Value of the various Articles of the Manufacture and Produce of the United Kingdom exported to Foreign Countries in 1828, and during each of the Eight Years ending with 1837; specifying their Value, the Countries to which exported, and the Value of those annually shipped for each.

Countries to which exported.	Exports.

See the *Commercial Dict.*; see also the *Treatise on Commerce* by the same author, from which part of the above article has been abstracted.

CO'MMISSARY (Lat. committo, *I entrust*), is used in various ways as nearly synonymous with *deputy*. In military affairs, the parties who provide clothing, &c. for the army are styled *commissaries*; and the whole body of officers belonging to this department, the *commissariat*.

COMMI'SSION. In the Army. *See* ARMY.

COMMISSION. In the Navy, the title of the appointment or warrant of officers of the rank of lieutenant, and above to hold their office. The commission is signed by the lords commissioners of the Admiralty.

COMMISSION, in Law, an appointment, usually by warrant or letters patent to one or more as commissioners, to perform certain duties specified in the instrument. In this mode many of the highest judicial or ministerial functionaries of the realm are appointed; thus, the judges of the superior courts hold several commissions, as of oyer and terminer, gaol delivery, &c. And high offices of state, when not regularly filled, are often entrusted to commissioners for the time being, and said to be put in commission; thus the custody of the great seal is put in commission in the absence of a lord chancellor and lord keeper. The Treasury and Admiralty have of late times been usually entrusted to commissioners, no lord high treasurer or lord high admiral having been appointed. The Court of High Commission consisted of persons appointed under letters patent to examine into matters of ecclesiastical jurisdiction, under stat. 1 Eliz. c. 1. (abolished 16 Car. 1.) Magistrates or justices of the peace are appointed by means of a commission, occasionally renewed, commonly termed the commission of the peace.

CO'MMISSU'RÆ. A term applied in Anatomy to certain parts of the brain which cross from one of its sides to the other. *See* BRAIN. In Botany, it signifies the place of junction of two opposite carpels.

COMMI'TMENT. In Law, the sending to prison of one charged with any crime. It appears to have been the ancient usage that whoever could lawfully arrest a person for felony or treason could also send or bring him to the common gaol; but since the Habeas Corpus Act it is the uniform practice that offenders are committed by the warrant in writing of a justice of the peace. The privy council and secretary of state can also commit in cases of treason. A commitment in writing must declare the authority of him who makes it, and also the nature of the offence with which the party is charged.

COMMI'TTEE, in the language of Parliament, is either a committee of certain members, or a committee of the whole house. (*See* PARLIAMENT.) *Select committees* are bodies appointed by open nomination or by a peculiar mode of election for the transaction of business, either according to the standing orders, or by accustomed usage. All private bills are referred in the first instance to select committees. *Joint committees* in former times consisted of bodies deputed by the two houses, and met for the purpose of adjusting differences, sometimes after free conferences had failed. They were free from the forms observed in conferences. As in the latter, the Lords deputed only half the number of members sent by the Commons. They have been long disused.

CO'MMODORE. A naval officer having the temporary rank of rear-admiral; the senior captain of several ships is called the commodore by courtesy.

CO'MMON. (Lat. communis.) In Law, is the right which one person has of taking a part of the produce of land, while the whole property in the land is vested in another. Common of pasture is either, 1. *Common appendant*, which is the right of the tenant of a manor to pasture his beasts on the lord's waste; 2. *Common appurtenant*, annexed to land by grant or prescription; 3. *Common in gross*, a right severed from the land.

When a common is under pasture all those who have a right of pasturage may turn out on it a certain number of animals, according to the extent of the enclosed grounds which they cultivate. When the common consists wholly or partly of arable land, this arable land is formed into ridges, generally with a narrow riband or balk of turf between each ridge, or between each two or three ridges. The right of cultivating these ridges is distributed among the holders of the enclosed lands of the parish, according to the extent of their possessions; and in order that there may be no partiality, and that every one may have as much interest in preserving his neighbour's ridge as his own, the ridges which any individual has the right of cultivating do not lie together, but are distributed among the ridges of his neighbours.

CO'MMONABLE LANDS. A common in which the greater part of the land is arable.

CO'MMON-FIELD LANDS. When the whole of a common belonging to a parish is not in a ring fence, but lies in different places, these places are called common fields.

CO'MMON MEASURE. In Arithmetic, is a number which divides two or more other numbers without leaving a remainder.

CO'MMON PLEAS, or COMMON BENCH, COURT OF. In Law, was originally that branch or side of the *aula regia* in which civil causes between subjects were tried. It was separated and rendered stationary, while that portion of the court from which the King's Bench is derived followed the person of the king by a provision of Magna Charta. This court has concurrent jurisdiction with the other two superior common law courts (*see* COURTS, SUPERIOR) in personal actions and ejectments. But it retains exclusive jurisdiction over all other mixed, and all real actions or pleas of

land. These, however, have now nearly fallen into disuse. (*See* PLEADING.) The Court of Common Pleas has one chief and four puisné judges.

COMMON PRAYER BOOK. The name given to the collection of all the offices of regular and occasional worship according to the forms of the church of England. The basis of this book is to be found in the King's Primer, set forth in 1546 by Henry VIII., which was intended to convey instruction to the people in the most important parts of the church service; but contained little more than the Creed, Lord's Prayer, Commandments, and Litany. This Primer underwent two revisions and republications under Edward VI., whose second Liturgy approaches very near in its contents to that which exists at present. It was at that review that the Sentences, Exhortation, Confession, and Absolution were prefixed to the Daily Service; the Decalogue was introduced into the Communion Service; and certain remnants of the Romish customs were finally abolished, as the sign of the cross in confirmation and matrimony, the anointing of the sick, and the prayers for the dead.

On the accession of Elizabeth, another review of the Liturgy was instituted; but the alterations effected were little more than in the selection of the lessons. At the review in the reign of James I., after the conference with the Presbyterians at Hampton Court, no change of importance was introduced, except the addition of the explanation of the Sacraments in the Catechism. Again, when on the restoration of Charles II. a conference had been held with the Dissenters at the Savoy, the subject of the Common Prayer Book was reconsidered in convocation. The services for the 30th of January and 29th of May were then added, as also the Form to be used at Sea. A few trifling alterations were made also in the other services; but these were the last that have been effected. On the accession of William III. another revision took place, and a considerable number of alterations were proposed and supported by many of the bishops and clergy; but they were rejected by convocation, and have never since been revived by authority. The following is a chronological list of the revisions of the Prayer Book in which any alterations have taken place. It is taken from the *Rev. T. V. Short's History of the Church of England:* —

1546. The King's Primer.
1548. The Communion Service.
1549. First Liturgy of Edward VI.
1550. First Ordination Service.
1552. Second Liturgy of Edward VI.
1552. Second Ordination Service.
1560. Liturgy of Elizabeth.
1604. Alterations introduced by James I.
1633. Alterations introduced by Charles I.
1661. Last Revision; authorized Liturgy.

COMMONS, HOUSE OF. *See* PARLIAMENT.

CO'MMON TIME. In Music, that in which every measure or bar contains one semibreve, two minims, four crotchets, eight quavers, and so on.

CO'MMONWEALTH. *See* REPUBLIC.

COMMONWEALTH OF ENGLAND. In History, the form of government established in England on the death of Charles I. in 1649, and which existed during the protectorate of Oliver Cromwell and his son Richard, until the abdication of the latter in 1659. The substitution of a democratical for a monarchical form of government was provided for and enjoined by two successive charters. The first charter of the commonwealth was drawn up in December, 1653, by the *council of officers*, who, on the voluntary resignation of the parliament in the early part of the same year, had declared Cromwell "Protector;" it was styled the "Instrument of Government." The second charter, called the "Petition and Advice," was framed in May, 1657, by the parliament which the protector had assembled in the previous year. Under the first charter, as has been well observed, the English government may be classed among republics with a chief magistrate at its head; under the second, it became substantially a monarchy, and Oliver Cromwell from 1657 to the period of his death was de facto King of England. (*Hallam's Constit. History*, 421.) On the demise of Cromwell, the succession of his son Richard was at first cordially recognized; but soon afterwards discontents and cabals having sprung up in the country, his inability or disinclination to govern induced him to abandon the protectorship after a reign of eight months; and on the 29th of May, 1659, the restoration of the monarchy under the old *regime* was effected by the triumphal entry into London of Charles II. It would be out of place to give here a detailed view of the state of England during the commonwealth. Suffice it to observe, all authors have concurred in opinion, that, whatever were the defects of the home government, arising partly from the ambition of the protector, and partly from the stubbornness and opposition of his councils, the energy and decision which Cromwell maintained in every department of the state not only laid the foundation of England's maritime greatness, but raised her to a pitch of prosperity that has rarely, if ever, been equalled.

COMMU'NION, is used in various ways in the general sense of participation: — 1. A person is said to be in communion with a church, who declares his acquiescence in its doctrines and participates in its worship; and hence the term communion is used sometimes for a church. 2. Communion is confined emphatically to participation in the Eucharist. (*See* EUCHARIST.) 3. The Communion of Saints, an article of the Apostles' Creed, is variously explained.

COMMUTA'TION. In Astronomy, the angle of commutation of a planet is the angle formed at the earth by a straight line drawn from the earth to the sun and the orthographical projection on the plane of the ecliptic of the straight line which joins the earth with the planet. It is measured by the difference between the sun's longitude and the geocentric longitude of the planet.

CO'MMUTATION OF TITHES. *See* TITHES.

COMO'SE. Ending in a tuft or kind of brush.

COMPA'NION. The hut or covering over a ladder (or staircase) in a ship.

COMPANY (Fr. *compagnie*), in its most general sense, means any two or more individuals associated for any common object, whether of business or pleasure.

In its more limited sense, however, and that in which it is usually understood in this country, the term company means an association of individuals for the prosecution of some industrious undertaking. Such associations may be of very various descriptions, inasmuch as the terms of the association or partnership may be varied in an infinity of ways. Generally, however, they may be said to be either *private* or *public* companies; that is, according to the law of England, companies with not more than six partners and with more than six; and public companies may farther be divided into *joint stock* and *regulated* companies, and these again into *incorporated* and *unincorporated* companies.

I. The principle on which associations for industrious purposes are established is too obvious to require much illustration. All great results are brought about by co-operation, and could not be effected otherwise. Isolated man is comparatively feeble and helpless; the capacity of associating for a common purpose is, in fact, the main source of his power, and the principal distinction between him and the lower animals — *Quo alio fortes sumus quam quod mutuis juvamur officiis?* One man has capital without skill, and another skill without capital: if such persons act independently, they will be able to effect little or nothing; but if they combine their efforts, and the capital of the one be applied and directed by the skill of the other, the effect of their exertions will be incomparably greater. But this is not all. Many of the greatest and most important works undertaken in modern times could not have been attempted by one individual, how opulent or skilful soever. Some of them require a vast outlay; while the returns being frequently remote and contingent, no single individual, and, indeed, no small number of individuals, would be willing to put their fortunes to hazard by engaging in them. But such undertakings are readily and advantageously carried on by large associations; for, in that case, individuals being called upon only to subscribe comparatively small sums to the common stock, they can afford to lose them without, in most instances, suffering any material inconvenience; while the aggregate amount of the subscriptions may, notwithstanding, amount to a very large sum, and be adequate to the greatest undertakings. In fact, some of the most gigantic works ever entered upon either in this or any other country have been accomplished by the joint contributions of the subscribers of 100*l.* shares. It is true that wealthy individuals usually subscribe for a number of such shares; but this does not affect the principle of the system, which is to distribute the risk according to the ability of the individuals associated.

II. In *private* companies the business is usually conducted by one or more of the partners on the principles laid down in the deed of partnership. The rights and obligations of the partners as respects each other are, of course, mainly determined by this deed: as respects the public, the law regards the act of one partner as the act of the company; and each partner is bound, without any regard to the sum he has subscribed to the company's stock, to the whole extent of his fortune, for the debts and engagements of the firm. Certain formalities are necessary at the withdrawal of a partner; such as advertizing in the *Gazette*, and the sending of special information of the fact to all individuals in the habit of dealing with the company. *See* PARTNERSHIP.

III. *Public* companies may, as already stated, be either joint stock or regulated; and these again may be either incorporated or unincorporated.

1. By a joint stock company is meant a company the stock of which is subscribed by a certain number of persons in shares of a certain amount. Thus, supposing that a joint stock association is to be formed for carrying on the business of banking or insurance, for excavating

a dock or a canal, or for constructing a railway, and that its capital is to amount to 1,000,000*l.* to be subscribed in shares of 100*l.* each; any individual (unless exceptions be made in the conditions under which the company is to be formed) who can command 100*l.* may become a partner of this association, and will be registered in the company's books as the holder of a share of 100*l.* of the company's stock. It is customary, too, in the vast majority of instances, to allow individuals to transfer their stock or shares to others, who succeed to all the rights and obligations of their predecessors. The price which shares or portions of stock fetch in the market depends, of course, on the real or supposed state of the company's affairs: if it be known or supposed to be in a flourishing and prosperous condition, and paying a high interest or dividend on its stock, the latter may sell for 10, 20, 50, or 100 per cent. or upwards of advance; whereas if it be known or supposed to be in an unprosperous condition, its shares may not bring a third or a tenth part of what they originally cost.

The affairs of companies of this description are usually conducted by salaried officers, who are appointed by and act under the orders of a board of directors chosen by the company at large, according to the conditions in their deed of association. The partners in such companies are all individually liable, without regard to the magnitude of their stock or shares, for the entire debts and obligations of the company.

At common law no action can be raised by or against such companies without making all the shareholders parties to the action. But the obvious and insuperable inconveniences that would result from the enforcement of this rule have made it be enacted, by the 1st Victoria, cap. 73., that the crown may at pleasure grant to joint stock associations letters patent, authorizing them to sue and be sued in the names of particular officers of their own; without, however, unless government judge proper, incorporating the company, or affecting the liability of the different partners for its debts.

2. When joint stock companies are incorporated by royal charter, or by letters patent, the liability of the partners is limited to the amount of their stock, and they cease to be responsible beyond that amount. This is the case with some great joint stock associations; as the banks of England, Scotland, and Ireland; the East India Company, the Royal Exchange Assurance, and a few more. But government has hitherto been, and that for the best reasons, very chary of granting charters of incorporation. It is difficult, in fact, to imagine a case in which they ought to be granted. Individuals are always ready to embark, without stipulating for any restriction of their liability, in any scheme, however hazardous, that holds out any promise of even a moderate return. And this unlimited responsibility of the partners is, in all ordinary cases, the only security worth a pinch of snuff on which the public can ever rely for protection against the fraud or misconduct of the managers of joint stock companies.

The grand distinction between unincorporated and incorporated joint stock companies is, that in the case of the former, the law looks only to the individuals forming the association; while, in the latter, it looks only to the corporate body, and pays no attention to the individuals of which it is made up. On judgment against an Incorporation, execution can only pass on the corporate property; and supposing it to become insolvent, the partners can only, as already stated, be called upon to make good the amount of the stock of the incorporation standing in their names. But it is quite otherwise with an unincorporated joint stock company: should it become insolvent, the partners, to use the words of Lord Eldon, are severally liable for the whole debts and engagements of the company, even "*to their last shilling and their last acre.*"

We have already sufficiently explained (see art. BANKS) the advantages that would result from the periodical publication of the names of the partners in joint stock companies. The public are clearly entitled to know who the parties are that embark in such concerns. Nothing on which it would be prudent to place much reliance can be learned from prospectuses and professions. Without knowing who the partners really are, the public have no means of forming any fair estimate of the character of any association, or of the credit to which it may be justly entitled. But we doubt whether it would be prudent to carry interference with joint stock companies farther than this. It is excessively difficult, and in most cases quite impossible, to enforce such regulations in regard to such companies as would serve to disclose the real state of their affairs, provided they had an interest in concealing it; and it is needless to say, that the leading of the public to depend on regulations that cannot be carried into effect, is one of the most likely means that can be resorted to for the encouragement of imposture and fraud.

3. *Regulated companies* consist of a number of unconnected individuals or associations engaged in the same business or department of trade, under condition of their conforming to regulations laid down for their common guidance. Such companies have been mostly formed for the prosecution of the trade with distant and peculiarly situated countries. Their principle is not to exclude individual competition, but merely to make the different parties engaged in the trade observe the same general rules. Companies of this description were at one time common; but they have now mostly fallen into desuetude, though it be easy to imagine circumstances in which they might be advantageously revived.

4. *Civic companies*, of which there are many in the the city of London and other large towns, are in reality *guilds* or *fraternities*. Originally they consisted of the parties carrying on a peculiar trade or profession; and in most instances they gradually acquired the privilege of prescribing the conditions and limitations under which individuals not belonging to the fraternity might obtain leave to engage in its peculiar trade within the precincts of the city or borough to which it belonged. In more modern times, however, the injurious influence of such restrictions on the free exercise of industry became obvious; and in consequence the powers formerly exercised by civic companies or guilds over individuals not free of their society, who attempted to carry on the same trade, have been either wholly repealed or greatly modified. At present, therefore, the companies in question exist principally as charitable institutions, or as incorporated associations, having, in many instances, the management of large amounts of property appropriated for the use of their poorer brethren, or for some similar purpose.

CO'MPANY. In the Army, a body of men, forming one of the chief divisions of a battalion of infantry. In the guards and artillery, a company consists of 120 men, but in all other infantry regiments of 100. A company in the infantry corresponds to *troop* in cavalry regiments; and is under the inspection of a captain, a lieutenant, and an ensign, besides the non-commissioned officers; with the exceptions of the artillery, engineers, marines, and the rifle brigade, in which *second lieutenants* are substituted for *ensigns*.

COMPA'RISON, or SIMILE. In Rhetoric, appears to differ from Metaphor (which see) only in form; the resemblance being stated in the first case, implied in the second. This is the sense in which the term Comparison is used and defined by Aristotle, in his *Art of Rhetoric*. Frequently the same idea furnishes at the same time both comparison and metaphor; as in the following line, "They melted from the field as snow." The word "melted" is used by transferring the property of the snow to a multitude of individuals: so far, therefore, the phrase is a metaphor; but the additional words, "as snow," transform it into a direct comparison. Perhaps, however, it might be more correctly said, in this instance, that the predicate "melted" is transferred by the figure termed Hypallage from the *snow* to the *multitude*, both words being used as subjects in the same sentence. The comparison, being as it were a metaphor resolved and rendered more flowing and less concise, is more appropriate to poetry than to prose composition. In fact, the only figures of this description which are generally admissible in prose writing are illustrations; *i. e.* arguments drawn from analogy in the form of comparisons. (*See* ILLUSTRATION.) It will generally be found that in every language the earliest writers, especially the poets, are the most addicted to the use of comparisons and metaphors of a highly figurative and bold character, as is especially observable with respect to the sacred poets, and to Homer; while as language advances in cultivation the metaphor comes more and more into ordinary use, and forms, as it were, the basis of composition, while at the same time it gradually loses the energetic and poetical cast which at first distinguished it.

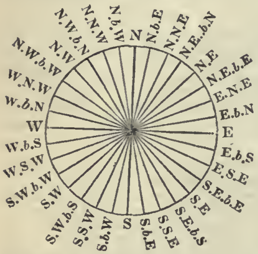
COMPARISON, DEGREES OF. Those varieties in the inflexions of adjectives which denote the degree in which a quality is possessed by a substance, either generally or in reference to one or more other substances. In English there are only two degrees of comparison, commonly named the comparative and the superlative. The first compares two conceptions only, as "John is *taller* than Charles." The second either compares one conception with a definite number of others, as "John is the *tallest* of all the four;" or expresses general superiority, as "the *fairest* of women."

COMPA'RTMENTS. (Ital. compartimenti.) In Architecture, the subdivisional parts of larger divisions for ornament, to which alone this term is properly applicable.

CO'MPASS. A name given to instruments contrived to indicate the magnetic meridian, or the position of objects with respect to that meridian. According to the purposes to which the instrument is chiefly applied, it becomes the *mariner's compass*, the *azimuth compass*, the *variation compass*, each particular application requiring some peculiarity of construction; but whatever modifications it may receive, the essential parts are the

same in all cases. These are a magnetized bar of steel, called the *needle*, having fitted to it at its centre a cap, which is supported on an upright pivot, made sharp at the point in order to diminish the friction as much as possible and allow the needle to turn with the slightest force. The *mariner's compass* has a circular card attached to its needle, which turns with it; and on the circumference of which are marked the degrees, and also the 32 *points* or *rhumbs*, likewise divided into half and quarter points. The pivot rises from the centre of the bottom of a circular box, called the compass box, which contains the needle and its card, and which is covered with a glass top to prevent the needle from being disturbed by the agitation of the air. The compass box is suspended within a large box, by means of two concentric brass circles or gimbals; the outer one being fixed by horizontal pivots, both to the inner circle which carries the compass box, and also to the outer box, the two sets of axes being at right angles to each other. By means of this arrangement the inner circle, with the compass box, needle, and card, always retain a horizontal position notwithstanding the rolling of the ship.

The notation of the mariner's compass is as follows:— The circumference being divided into the four quadrants by two diameters at right angles, the extremities of these diameters are the four cardinal points (cardo, *a hinge*), marked N., S., E., W. (north, south, east, west). Bisecting each of the quadrants, the several points of bisection are denoted by placing the two letters at the extremities of the quadrant in juxtaposition. Thus, N.E. (north-east) denotes the point which is half way between north and east; and so with N.W., S.E., S.W. (north-west, south-east, south-west). Let the octants next be bisected; the points of division are denoted by prefixing to each of the above combinations first the one, and then the other of the two cardinal points of which it is formed. Thus N.E. gives N.N.E.



and E.N.E. (north north-east, and east north-east); and so in respect of the others. Sixteen points have thus been named. Let the distances be again bisected; then each of the points so found is expressed by that one of the preceding points already named to which it is nearest, followed by the name of the cardinal point towards which its departure from the nearest points leads it, the two being separated by the letter *b*(by). Thus, the point half way between N. and N.N.E. is N. by E. (north by east); that which is half way between N.N.E. and N.E. is N.E. by N. (north-east by north), &c. The whole of the thirty-two points are thus distinguished, as in the figure.

The principal requisites of a compass are intensity of directive force, and susceptibility. The first of these is obtained by constructing the needle of the material and form best suited to receive and retain the magnetic virtue. A number of experiments on this subject were made by Coulomb, and more recently by Captain Kater, an account of which is given in the *Phil. Trans.* for 1821. Captain Kater found that the kind of steel capable of receiving the greatest magnetic force is shear steel; and that the best form is that of a lozenge or rhomboid (*fig.*), cut out in the middle, so as to diminish the extent of surface in proportion to the mass, it being found that the directive force of the needle, when magnetized to saturation, depends not on the extent of surface, but on the mass. Beyond a certain limit (about five inches) no additional power is gained by increasing the length of the needle; and needles exceeding a very moderate length are apt to have several consecutive poles, the effect of which is to produce a great diminution of directive force. On this account short needles, made very hard, are to be preferred.

Like many other of the most valuable arts of life, the origin of the compass is entirely unknown. By some writers it is ascribed to Flavio Gioja, who lived in the 13th century; yet Guyot de Provence, who lived a century earlier, speaks of the loadstone, to which he gives the name of *marinetti*, or mariner's stone, as useful to navigation. Others pretend that it was invented in France; but there seems to be no other reason for this supposition than the fact that from time immemorial the north point of the compass card has been distinguished and ornamented with a *fleur de lis*. For a reason of a different kind, but perhaps of the same degree of weight, Dr. Wallis and others have supposed the invention to belong to England, the name *compass*, which is given to the instrument by most European countries, being used in England to signify a circle. The term *bussola* in Italian, and *boussole* in French, has also been supposed to be derived from our term *box*, by which the compass is frequently designated. Gilbert, in his celebrated work *De Magnete*, affirms that Marco Polo brought the invention to Europe from China, about the year 1260. It appears very probable that the Chinese were acquainted with the directive property of the loadstone at an early period. Their method is to place it on a small piece of cork and set it to float on water. The art of communicating the magnetic virtue to steel, and suspending the needle on a pivot, is undoubtedly an European invention.

The *azimuth compass*, being intended to show the bearing of objects in respect of the magnetic meridian, has its circle divided merely into degrees, instead of the rhumbs used in navigation, and is provided with sights to allow the angles to be taken more accurately.

The *variation compass* is designed to exhibit the diurnal changes in the deviation of the magnetic from the true meridian; and the needle is generally made of much greater length than in the mariner's compass, in order to render minute variations more sensible. *See* MAGNETISM.

COMPITA'LIA. (Lat. compitum, *a street*.) A Roman feast celebrated in honour of the Lares and Penates. Under Tarquinius Superbus, it is said that human victims were sacrificed at this solemnity. The gods invoked at it were termed Compitales, as presiding over the streets.

CO'MPLEMENT. (Lat. compleo, *I fill up*.) What is wanted to complete or fill up some quantity or thing. Thus, the complement of an angle is what is wanted to make the angle a quadrant or 90°. Complement of a number is what is necessary to be added in order to make the number 1, or 10, or 100, or, in general, 1 with zeros. In Geometry, the complements of a parallelogram are the two spaces which, with the parallelograms about the diagonal, make up the whole parallelogram.

COMPLU'VIUM. (Lat.) In Ancient Architecture, an area in the centre of the Roman houses, so constructed that it might receive the waters from the roofs. It is also the gutter or eave of a roof.

CO'MPOSITE NUMBERS, in Arithmetic, are numbers which can be divided by some other number greater than unity. They are consequently opposed to *prime numbers*, which admit of no divisor. In Music, *composite numbers* are such as are composed by the multiplication of the prime integers, 2, 3, 5.

CO'MPOSITE ORDER. In Architecture, one of the five orders of architecture, and, as its name imports, composed of two others, the Corinthian and the Ionic. Its capital is a vase with two tiers of acanthus leaves, like the Corinthian; but instead of stalks, the shoots appear small and adhere to the vase, bending round towards the middle of the face of the capital; the vase is terminated by a fillet, over which is an astragal crowned by an ovolo. The volutes roll themselves over the ovolo to meet the tops of the upper row of leaves, whereon they seem to rest. The corners of the abacus are supported by an acanthus leaf bent upwards. The abacus resembles that of the Corinthian capital (*see* CAPITAL). In detail the Composite is richer than the Corinthian, but less light and delicate. Its architrave has usually only two fasciæ, and the cornice varies from the Corinthian in having double modillions. The column is ten diameters high. The principal examples of this order are the Temple of Bacchus at Rome, the arch of Septimius Severus, those of the Goldsmiths and of Titus, and that in the baths of Diocletian. The example here given is from the arch of Titus, which is considered a fine specimen of the order. *See* ORDER.

COMPO'SITÆ. In Botany, the largest of all known natural groups of plants; and so called because the old botanists who invented the name regarded the flower-heads as compound flowers. They answer to the *Syn-*

genesia polygamia of Linnæus, and are positively characterized by having capitate flowers, syngenesious anthers, and an inferior ovary with a single erect ovule. In the most recent account of this order, by M. De Candolle, nearly 8000 species are enumerated in about 900 genera, and the subject is not nearly exhausted; they exist all over the world where vegetation can develope, and are sometimes trees, although more generally herbaceous plants or shrubs. Among medical species, the chamomile, wormwood, southernwood, elecampane, and opium lettuce are conspicuous; of esculents, the order contains the artichoke, the Jerusalem artichoke, the lettuce, succory, and endive; and among ornamental plants, the aster, dahlia, coreopsis, sunflower, &c. But by far the greater part of this large assembly consists of species which are either weeds or of no known use. The reader who wishes to become acquainted with this order must consult *De Candolle's Prodromus Regni Vegetabilis*, vols. v., vi., and vii.

COMPOSI'TION. In Law, an agreement made between the owner of lands and the parson, with the consent of the ordinary and the patron, that such lands shall be discharged from the payment of tithes, by reason of some land or other real recompence given to the parson in satisfaction thereof. Such an agreement, since the 13 Eliz. c. 10., is not good for a longer term than three lives or twenty-one years. *Composition* signifies also the agreement between a bankrupt after his last examination and nine tenths of his creditors for the satisfaction of their claims, and has the effect of superseding the fiat of bankruptcy.

COMPOSITION. In the Fine Arts, that combination of the several parts, whereby a subject is agreeably presented to the mind, each part being subordinate to the whole. See INVENTION.

COMPOSITION. In Music, the art of disposing and arranging musical sounds into airs, songs, &c., either in one or more parts, for voices or instruments or both. Zarlino defines it to be the art of joining and combining concords and discords together, which are the matter of music.

COMPOSI'TION OF FORCES or MOTION. In Mechanics, signifies combining or uniting several forces or motions, and determining the result of the whole. If a body is solicited by two forces which act in the same direction, the *resulting* force, or *resultant*, is equal to the sum of both; that is to say, the effect produced is the same as would be produced by a single force acting in the same direction, and equal to their sum. If the two forces act in opposite directions, the resultant is equal to their difference, and the body will move in the direction of the greater. If the lines of direction of the two forces make an angle with each other, the resultant will be a mean force in an intermediate direction. Thus, if the two forces be represented in intensity and direction by the two sides of a parallelogram, then the resultant is represented in intensity and direction by the diagonal of the parallelogram which passes through the angle formed by those two sides.

COMPO'SITOR. (Fr. compositeur.) In Printing, the workman who arranges the types in lines and pages, and prepares them for being printed off.

COMPOSTE'LLA, ST. JAMES OF, or ST. JAMES OF THE SWORD. An ancient order of knighthood in Spain, the chief of the four military orders (Compostella, Calatrava, Alcantara, Manresa); probably founded either by Alphonso IX. of Castile (1158, 1214), or Ferdinand II. of Leon (1157, 1188). It originally began from the voluntary association of certain gentlemen to defend the great road leading to the celebrated shrine of St. James at Compostella. Pope Alexander III. gave the order its rules of government. The order possessed at one period eighty-four commanderies, with two cities and numerous burghs and villages. The knights take the vows of poverty, obedience, and conjugal chastity; to which they add a fourth, "to defend and maintain the immaculate conception of the Holy Mother of Jesus Christ."

CO'MPOUND INTEREST, is interest charged not only on the principal, but also on the interest forborne. Thus, if money is invested so that the interest is not paid as it becomes due, but successively added to the capital, the capital is said to accumulate at compound interest. Let $r =$ the amount of 1*l.* for 1 year; that is to say, $= 1$*l.* with its interest added to it; then the amount of 1*l.* at the end of 2 years will be r^2; at the end of 3 years, r^3; at the end of 4 years, r^4; and so on. The law of this country does not allow compound interest to be charged on money lent.

COMPRE'SSIBI'LITY. The quality of bodies in virtue of which they can be reduced to small dimensions. All bodies, in consequence of the porosity of matter, are compressible, though liquids resist compression with immense force.

CO'MPTONITE. A mineral found in ejected masses on Vesuvius; named after Lord Compton, who first brought it to England in 1818.

COMPURGA'TION. An ancient mode of trial both in civil and criminal cases. In the latter, by the law of the Saxons (which William the Conqueror confirmed in this respect, at least as to its main features), the accused party was allowed to clear himself by the oath of as many of his neighbours to his innocence as amounted in collective worth, according to the legal arithmetic of the Anglo-Saxons, to one pound (*see* WEREGILD), if he could in the first instance (being a villein) obtain the testimony of his lord that he had not been previously convicted. If otherwise, he was bound to undergo ordeal, or wage his law with a greater number of compurgators. Compurgation in criminal cases was abolished in general by Henry II.'s assizes, the ordeal being enforced in lieu of it. But it was retained as a special franchise in some boroughs, to which those assizes did not extend; and the last instances of it on record are to be found in the rolls of the hundred court of Winchilsea, in the reign of Henry VI. (See *Sir F. Palgrave on the British Commonwealth*.) A singular usage of the same description long remained in the ecclesiastical courts, by which convicted clerks, allowed their clergy and delivered up to the ordinary, were admitted to purge themselves by the oaths of compurgators, which was abolished by 18 Eliz. c. 7. Wager of law, in civil cases, lay in some personal actions only, and in incidental traverses in real actions (see *Blackstone*, lib. iii. c. 23.); and in these cases, although many technical difficulties prevent defendants from availing themselves of it, it is not yet abolished.

COMS, COOMS, COOMES, or CHIVES. The points of the radicles of malted grain, which after kiln-drying drop off during the process of turning. They are sold by maltsters under the name of malt dust, and are considered excellent manure.

CONCE'PTACLES. (Lat. conceptaculum, *a receiver*.) The cases containing the reproductive organs of such plants as ferns, in which they are produced from the back of the leaves, growing in the form of spots at the anastomoses, margins, or extremities of the veins, and then collectively called Sori. The conceptacles are also termed Capsules, Thecæ, and Sporangia.

CONCEPTA'CULUM. (Lat. *a receiver*.) A term in Botany, denoting a one-valved fruit opening longitudinally on one side, and distinct from the seeds. It is a folliculus without any attachment between the placenta and the ventral suture, as in Asclepias.

CONCE'PTION. (Lat. concipere, *to conceive*.) In Mental Philosophy, that faculty or act of the mind by which we combine a number of individuals together by means of some mark or character common to them all. We may observe, for instance, that equilateral isosceles and scalene triangles all agree in one respect, that of having three sides; and from this perceived similitude we form the conception *triangle*.

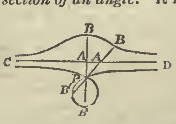
CONCERTA'NTE. (It. concentare, *to contrive*.) In Music, a term expressive of those parts of a musical composition that sing or play throughout the piece, as distinguished from those that play only occasionally in particular places.

CONCE'RTO. (It.) In Music, a piece composed for a particular instrument, which bears the greatest part in it, or in which the performance is partly alone and partly accompanied by other parts.

CONCE'TTI. (It.; rendered by English writers on rhetoric *conceits*.) Ingenious thoughts or turns of expression, points, jeux d'esprit, &c. in serious composition. In the 16th century, the taste for this species of brilliancy, often false and always dangerous, spread rapidly in the poetical composition of European nations, especially in Spain and Italy; where the name of *concetti* was applied rather in a good than a bad sense, the critical taste being much perverted. Tasso is not free from *concetti*. After his time they became offensively prominent in Italian poetry for a century afterwards: Marino and Filicaia offer strong examples. In France, the mode of concetti was equally prevalent in the 17th century, and was peculiarly in vogue with the fair critics of the Hotel Rambouillet, so well known by Moliere's "Précieuses Ridicules." In England, Donne and Cowley are instances of a style full of *concetti*.

CO'NCHIFERS. (Lat. concha, *a shell*, and fero, *I carry*.) A name applied by Lamarck, Schweigger, and Latreille to all mollusks which are protected by a bivalve shell.

CO'NCHOID. (Gr. κογχη, *a shell*, and εἶδος, *form*.) The name given to a curve invented by Nichomedes for the solution of the two famous geometrical problems of antiquity, — the *duplication of the cube*, and the *trisection of an angle*. It is constructed as follows: —



Let P be a given point through which any straight line is drawn to cut or meet another straight line C D given in position; if a segment AB (or AB′) of a given length be taken on either side of C D, the point B (or B′) will trace the conchoid. The curve has different forms, according to the different relative

positions of the point B with respect to the pole P and the given straight line C D. The conchoid is a curve of the fourth order, the equation between the rectangular co-ordinates (the origin being placed at A in the straight line perpendicular to C D) being $x^2 y^2 = (a^2 - y^2)(b + y^2)$, in which A B $= a$, and A P (perpendicular to C D) $= b$.

CONCHO'LOGY. (Gr. *κογχη, a shell,* and *λογος, a discourse.*) The science of shells: that department of Malacology which treats of the nature, formation, physiological relations, and classification of the hard parts or skeletons of the molluscous animals.

As Osteology, inasmuch as it relates to the nature, development, and physiological subserviencies of the skeletons of the vertebrate animals, is a science in the strict acceptation of the term, so also is Conchology under the like applications; but as no naturalist has yet conceived a classification of vertebrate skeletons independently of the softer organs of the body which they support and protect, and as, notwithstanding that the complex internal skeletons of the Vertebrates are closely related to their general structure and habits, the classification of these parts would not in all cases tally with the natural arrangement of the animals to which they belonged, therefore still less scientific must be a classification of shells merely, apart from a consideration of the molluscous animals by which they are secreted. For shells, instead of consisting, like bones, of living organized substance permeated by blood-vessels, absorbents, and nerves, are mere inorganic laminated, concretionary, or crystalline deposits of calcareous earth, more or less combined with albuminous matter: they are also formed in the skin, and are appendages to the dermal system, which in all classes of animals is the principal seat of variety. In many cases, therefore, there exists very little correspondence between the structure or even the presence of a shell and the general character of the organization of a mollusk; and the absence of uniformity between the condition of the shell in closely allied species is exemplified in the highest as well as the lowest classes of the molluscous sub-kingdom. The argonaut, the poulp (*Octopus*), the calamary, the cuttle-fish, and the spirula, all possess the same peculiar and highly developed organization; and in a classification founded on general structure, and expressive of the true affinities of its objects, they must rank in the same order of their class. But the shells of these mollusks present respectively the following conditions:—the first, a simple, external, light, elastic, subtransparent, but calcareous discoidal univalve; the second, two internal, friable, subtransparent styles, composed of hardened albumen; the third, an elongated, feather-shaped, horny plate; the fourth, an internal, compressed, oval, laminated, friable, calcareous mass; the fifth, an elongated, cylindrical, conical shell, twisted spirally in the same plane, divided into chambers by calcareous partitions, perforated by a siphon, and partly internal, partly external, in its situation. Now, in a system of Conchology, understood as the classification of shells in the abstract, these productions would necessarily be dispersed into five widely different groups; and in like manner, the small, thin, and flat plate, which is buried in the substance of the mantle of the slug, would be far removed from the large external spiral shell of the snail.

But no conchologist groups together his shells strictly and exclusively, according to their resemblances; all the testaceous productions of the Cephalopods, now that the real affinities of these mollusks are known, are arranged in the same group, notwithstanding their striking discrepancies of texture and form, and in their relative size and position to the bodies of their fabricators: so likewise with the shells or their rudiments of the air-breathing Gastropods, or of the Pteropodous Mollusca. In short, every purely conchological system must undergo modifications corresponding with the progress which is made in the knowledge of the true natural affinities of the molluscous animals; and the progress of Conchology is therefore essentially connected with that of *Malacology*, under which term an outline of the most approved classification of the Mollusca and their shells will be found.

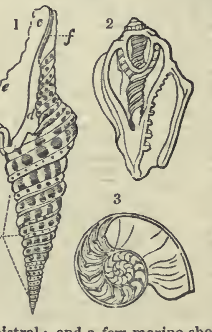
Under the present head will be briefly treated those points which relate to Conchology as a science; viz. the development, structure, configuration, and physiological subserviencies of shells.

The formation of a shell commences with the exudation of layers of albumen from the outer surface of the mantle or skin of the embryo mollusk, which is generally followed by the admixture of rhombic or prismatic crystalline particles of the carbonate of lime: and this first-formed shell of the embryo constitutes the nucleus of the shell of the mature mollusk. The nucleus is developed in most cases before the embryo quits the egg-coverings, but it is never "coeval with the first formation of the animal;" it is preceded by several distinct stages in the development of the embryo. The subsequent growth of the shell depends upon the deposition of fresh layers to the inner surface of the circumference of those previously formed; beyond which the new-formed layers extend in proportions which determine the figure of the future shell.

Sometimes the calcifying margin of the mantle extends outwards at an obtuse or right angle to the last-formed margin of the shell; and after having deposited a calcareous plate in this position, is retracted and absorbed, to be again similarly produced and extended after ordinary growth has proceeded to a certain extent. It is to this periodical growth of the mantle and plethoric condition of the calcifying vessels that the ridges on the exterior of the shell in the *Venus plicata* among Bivalves, and in the *Scalaria pretiosa* among Univalves, are due. Should the mantle, instead of being uniformly extended, send outwards a number of detached tentaculiform calcifying processes, these will form a row of spines corresponding in length and thickness to the soft parts on which they are moulded; and as the calcifying processes continue to deposit shelly material during the progress of their absorption, the spines, which were at first hollow, thus become solidified, and are soldered to the margin of the shell. This development of calcifying processes or filaments of the mantle and spines may likewise alternate with periods of the ordinary formation of the shell; and thus the exterior of the shell may become bristled with rows of spines, as in some species of *Spondylus*, and in the *Murex crassispina*.

The most simple form of shell is the cone, which may be much depressed, as in the genus *Umbrella;* or extremely elevated and contracted, as in the *Dentalium;* or of more ordinary proportions, as in the limpets (*Patellæ*). The apex of the cone is oblique and excentric; directed, in the limpets, the argonaut, and the nautilus, towards the head, but in most other mollusks towards the opposite extremity of the body. A shell may consist of one piece, as in the Inopercular Univalves; or of two pieces, as in the Opercular Univalves and most Bivalves; or of three pieces, as in *Terebratula;* or of four or more pieces, as in some of the *Pholades* and the Multivalves proper, or Chitons. With respect to the operculum, this part is sometimes calcareous, but it consists frequently of albuminous membrane only, or is *horny;* thus presenting the condition which the univalve shell itself presents in certain genera, as *Aplysia*, *Loligo*, &c.

The conical univalve shell is generally spirally convoluted; sometimes, as in the *Nautilus* (*fig.* 3.), in the same plane, more usually in an oblique direction, as in *fig.* 1 and 2. As a general rule, the spiral univalve, if viewed in the position in which its inhabitant would carry it if it were moving forwards from the observer, is twisted from the apex downwards, from left to right, the spire being directed obliquely towards the right (*a*, fig. 1., indicates the spiral turns of *Pleurotoma*). In certain genera, as *Clausilia*, *Physa*, the shell is twisted in the opposite direction: such shells are called "perverse," or sinistral. Some species of *Bulinus*, *Partula*, and *Pupa* are sinistral; and a few marine shells, as *Fusus sinistrorsus*, also exhibit the reverse of the ordinary disposition of the spire.



The part around which the spiral cone is wound is termed the "columella." This is sometimes simple, sometimes plicated, as in the *Voluta musica* (fig. 2.); it is also sometimes solid, sometimes hollow: when the latter, its aperture is termed the *umbilicus*. (*f*, fig. 1.) The opening forming the base of the spiral univalve is bounded by an inner lip *d*, and an outer lip *e*: the inner lip offers a smooth convex surface, over which the foot or locomotive disk of the mollusk glides to reach the ground.

In many Univalves, the aperture of the shell is entire; in others, it is broken by a notch, or perforated by one or more holes; or a portion of it is produced into a canal or siphon (*c*, fig.1); or it may present a pallial notch (*b*, fig.1.) opposite to the siphon). These modifications are important, on account of the constancy of their relation to certain conditions of the respiratory organs: thus the conchologist, in grouping together all the spiral univalve shells of which a part of the margin was either notched or produced into a grooved siphon, would really indicate a very natural tribe of Mollusca, every species of which he might be assured was aquatic and marine, and breathed by means of two gills having a pectinated structure, to which the water is conducted by a fleshy tube. Were a like correlation between the shell and its inhabitant to hold good in other families of Mollusca, the classification of shells

would then be a subject of much importance, and worthy the attention of the scientific naturalist: unfortunately, the reverse of this is frequently the case.

The part called the *operculum*, which is present in certain univalve mollusks, is a plate consisting of layers of sometimes calcified, sometimes uncalcified, albumen, attached to a disk at the back part of the foot, and forming, when this is retracted, a more or less perfect defence to the outlet of the shell.

Some opercula increase by the addition of matter to their entire circumference; and these are either concentric, as in *Bithynia* and *Paludina*, or excentric, as in *Ampullaria* and most of the Pectinibranchiate mollusks: other opercula grow by the addition of matter to part of their circumference; and these are either spiral or imbricated: in the latter, the layers of growth succeed each other in a linear series. No operculum presents an annular form. As the operculum sometimes varies in structure in species of the same genus, as, *e.g.*, of *Vermetus;*—since, moreover, this part is inconstant even as to its presence in species of the same genus, as in the Volutes, Cones, Mitres, and Olives; and as some genera in a natural family, as *Harpa* and *Dolium*, among the Buccinoids, are without an operculum, while the other genera of the same family possess that appendage, it obviously affords characters of very secondary importance in a scientific classification of the Univalve Mollusca. Much confusion indeed might have been introduced into the science of Malacology if the opinions of those conchologists who have proposed to classify shells from the modifications of the operculum had been much respected by naturalists.

True bivalve shells are peculiar to the Acephalous Mollusca; and their presence is constant, although they are in a few instances too small to cover the whole of the body, and in the ship-borers (*Teredo*) exist only as small instruments, limited to the function of excavating the burrows inhabited by these mollusks. But all the species in which the bivalve shell is inadequate to the protection of the whole of the body derive extrinsic defence by burrowing in sand, or stone, or wood; and they also commonly line their burrows with a layer of smooth and compact calcareous matter, forming a tube. This calcareous tube, in some cases, is of considerable size and thickness, as in the *Teredo gigantea* or *Septaria* of Lamarck. In the *Clavagella* one valve, and in the *Aspergillum* both valves, are soldered to this tube, which, in the latter, presents a peculiar modification of its exposed extremity, which resembles the end of the spout of a watering-pot. No two shells can present a greater contrast than do those of the *Placuna* and *Aspergillum;* yet the organization of their respective constructors is essentially the same. In a classification of shells, the calcareous tubes of the *Dentalium*, *Serpula*, *Aspergillum*, *Vermetus*, &c., would be associated in the same general group; but it needs only to observe how these products of animals, belonging not only to different classes, but to distinct primary divisions of the animal kingdom, are arranged in the cabinets of collectors, to be convinced that Conchology, as a classificatory science, apart from Malacology, no longer exists.

With regard to the structure and physiological relations of bivalve shells, it may be observed, first, that in all Acephalous Mollusca which breathe by distinctly developed lamellated gills (*Lamellibranchiata*), one valve corresponds to the left, the other to the right side of the animal; but in the Brachiopodous Bivalves, one valve is applied to the ventral, and the other to the dorsal aspect of the animal.

In all the Lamellibranchiate Bivalves which are free, the two valves are symmetrical, and the shell is termed *equivalve;* in all those which adhere by one of their valves to foreign bodies, this valve is deeper and larger than the unattached valve: such shells are termed *inequivalve*. Of those Acephalans which are attached to foreign bodies by means of a byssus, some, as *Tridacna*, *Saxicava*, and *Bysso-arca*, are equivalve, and both valves are notched, to form the hole for the passage of the byssus; while others, as the *Pectines*, *Aviculæ*, and *Peda*, are inequivalve, the byssus passing through a groove in the right valve.

Linnæus, who first introduced precision into the description of shells, defined several points requisite to be noticed in the outer and inner surface of a bivalve shell, but the prurient epithets, which his comparison of the bivalve selected for illustration induced him to attach to those parts, have been abandoned and changed. If the shell of the common cockle (*Cardium edule*) be examined, each valve will be seen to be produced into a conical prominence, bent towards, and nearly meeting at, that part by which the valves are joined together. These prominences are termed the *umbones*. The apex, or beak of the umbo, corresponds to the apex of the univalve shell, and is the point at which the development of the bivalve commences. When the apex is directed in the transverse plane of the shell, and so placed that a bisection of the shell in that plane through the apices shall divide the valve into two equal parts, the shell is termed *equilateral:* of this form the common scallop (*Pecten*) is an example. When, upon a similar division, a slight difference is observed in the two valves, the shell is termed *sub-equilateral;* but where the difference is well marked, it is an *inequilateral* bivalve. When the apex is bent, as is commonly the case, out of the transverse plane, it is always directed more or less towards the anterior part of the shell; if such a Bivalve shell as a *Cytherea* or *Isocardia* be held before the observer, with the umbones directed forwards and the hinge above,—in the position, in fact, in which the living animal would place itself if it were creeping forwards from the observer,—the right valve will of course correspond with the right hand of the observer, and the left with the left. (*Fig.* 4. is the left valve of a *Cytherea; a* is the upper or dorsal margin, *b* the lower or ventral margin, *c* the anterior, *d* the posterior margin, *e* the apex of the umbo, *f* the lunule.) Now, if a Bivalve in which the apices have a spiral twist, as an *Isocardia* or *Diceras*, be placed in the above position, and compared with the univalve shell of a *Concholepas* or *Purpura*, it will be seen that the left valve corresponds with the ordinary or dextral spiral Univalve, and the right valve to the perverse or sinistral Univalve. Instances, however, have been met with where the characters of the valves of the Bivalve were reversed, like the occasional exceptions in the "perverse" sinistral Univalves before mentioned.

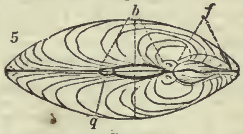
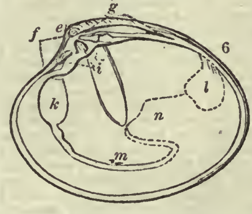
5



6



When the circumference or margin of one valve fits exactly at every part to that of its fellow, it is said to be "regular," or entire; but if it be notched at any part, so as not to come into contact with the corresponding part of the opposite valve, it is "irregular," or emarginate.

With respect to the outer surface of a Bivalve, the parts called *umbones* and *apices* have already been defined, and the upper or dorsal and anterior margins of the valve determined; if we continue our examination of the exterior surface of the Bivalve, we shall find, in most cases, anterior to the apices, a depression of variable extent and depth. This is the "lunule" (*f*, fig. 5.): it may be cordiform, or crescentic, lanceolate, oval, oblong, deep, superficial, &c. Behind the apices is another depression, longer and narrower than the lunule, and which is called the "fissure" (*g*, fig. 5.), and its margins lips. Behind the fissure there is sometimes a small depression, called the "suture" (*h*, fig. 5.). The general more or less convex surface of each valve is called the "venter," or belly, which terminates in the *limb*, circumference, or margin.

The most important part of the margin is that which is modified to form the joint or hinge upon which the two valves open and shut. This part is called the "cardinal edge," and generally presents certain prominences and depressions, the projections of one valve interlocking with the depressions of the other. The projections or "teeth," together with the cavities or "cardinal pits," are very regular in their formation in each genus and species of Bivalve. What is of more importance is, that every modification in the structure of the hinge is generally found to coincide with some recognizable and more or less important difference in the organization of the soft parts; so that conchologists have justly attached great value to the characters derivable from the hinge, especially for the purpose of generic distinctions. When the teeth are situate beneath the apex or centre of the hinge, they are called *cardinal;* when they are removed from the centre of the hinge, they are named *lateral teeth* (*i*, fig. 6.); when two only are present, one is called anterior, the other posterior; when there are three, they are distinguished respectively as the anterior, median, and posterior teeth; but when the hinge is composed of a great number of teeth, it is said to be "serial," as in *Arca*. The direct medium of union of the two valves is a dense fasciculus of elastic

albuminous fibres, generally of a brown colour, called the "ligament," or "elastic ligament." The fibres of this part are attached by their extremities to the two valves, which, in most cases, present a particular depression for their reception. The ligament is always so long as to prevent the actual closing of the valves, except when its elasticity is overcome by a certain force, as by that of the contraction of the adductor muscle or muscles: thus the inorganic power of elasticity is made the direct antagonist of a vital and muscular contraction; and as the patent condition of the bivalve shell is that which the exigencies of the animal most constantly require, it is assigned to a force which can act without ever causing fatigue, while the occasional or protective action of forcibly closing the valves is due to an action under the immediate control of the will or instinctive sensation. The modifications of the internal surface of a bivalve shell are, perhaps, the most interesting and important; as they relate immediately to the structure of the soft parts, and bespeak the general nature of the organization of the animal. Hence they afford the characters by which the habits and structure of an extinct genus may be to a great extent determined.

The adductor muscles leave well-marked impressions on the inner surface. If there be but one muscular impression on a valve, then it belongs to a "*monomyary*" or "unimuscular" Bivalve; and if neither valve of a fossil shell presenting this character have been immediately attached to foreign bodies, then the laws of co-existence warrant the inference that the constructor of such a Bivalve possessed a byssus, and the muscular organ called the foot; but that the foot was developed only to the extent adapted to serve as an instrument for moulding the soft fibres, and regulating the attachment of the byssus.

If each valve of a bivalve shell exhibit two muscular impressions, it proves the species to be "dimyary" or "bimuscular" (*k* is the anterior, and *l* the posterior muscular impression in the *Cytherea*, fig. 6.); if, moreover, there be a thin small muscular depression beneath the cardinal hinge, we have then an indication that the animal possessed a large foot, organized to serve as a locomotive or burrowing fleshy organ, the retractive muscle of which was inserted in the above depression. The line continued between the impressions of the two adductors indicates, by its depth and breadth, the development of the muscular margin of the mantle, and is called the *pallial impression* (*m*, fig. 6.). If this line be continued uninterruptedly, parallel with the margin of the valve, we may be assured that the animal was either without siphons, or had them of very small size; but if the pallial line be broken by an angular notch (*n*, fig. 6.) continued inwards before its junction with the posterior muscular impression, then it may be certainly inferred that the animal had well developed muscular tubes or siphons for respiration, with all the concomitant powers and habits. Thus the general organization of the soft and perishable fabricator of a bivalve shell may be as certainly determined by the evidence of its fossilized enduring case, as that of a vertebrate species by the structure of its skeleton. The more immediate affinities of the Bivalve are revealed by the modifications of the hinge.

It sometimes happens, however, that the whole of the internal or nacreous stratum of a fossil bivalve shell is destroyed, especially if it have been imbedded in porous chalk; and as the muscular impressions and the articular structure of the hinge are composed exclusively of the inner stratum of the shell, the means of determining the nature and affinities of the animal in that case are lost; and, unless the observer were acquainted with the texture and structure of the bivalve shell, he would run the risk of mistaking the part of a decomposed Bivalve for the whole of some nondescript "Acardian" species, as those Bivalves are termed in which the hinge is naturally wanting.

Each valve of a bivalve shell consists of two strata, distinct in texture and in their organs of formation: the internal stratum is deposited in nearly parallel layers, by the central and posterior parts of the mantle: it forms the smooth iridescent lining of the shell called "mother of pearl;" the outer stratum is secreted by the thick glandular margin of the mantle, and consists of conical fibres, resting obliquely by their apices, or narrower ends, upon the nacreous laminæ. The thickness of the two strata of the shell always preserves an inverse ratio, the outer one being thinnest at the *umbo*, and thickest at the margin; the inner one the reverse.

One hundred parts of oyster shell give—

Of carbonate of lime	98·3
Phosphate of lime	1·2
Insoluble animal matter	0·5
	100·0

Most univalve shells are composed of three strata, which consist of layers of rhombic or prismatic crystals, differently arranged in the adjoining strata. The chief difference of structure depends on the relative quantity of the animal to the earthy constituents of the shell.

Hunter discovered that the molluscous inhabitants of shells had the power of absorbing a part of the shell previously formed; a fact which has been confirmed by subsequent observers, and which gives rise, in several species, to singular modifications in the form and structure of the shell in the progress of growth. Another change of form is due to the physical decomposition or destruction of a part of a shell: this occurs to the apex of certain Univalves, after they have been evacuated by their original occupant, in the widening and lengthening the shell to accommodate it to an increase of bulk. Such shells are said to be "decollated," as in *Cerithium decollatum*, *Helix decollata*, &c. An analogous partial decomposition always obtains in many *Uniones* and *Anodontæ*, of which the "umbones" are then said to be "decorticated," the external coloured layer or bark of the shell being worn away. There is no general law or uniformity in the mode in which the inhabitants of either univalve or bivalve shells dispose of that part of their calcareous abode which they evacuate in the progress of their growth. In the decollated shells, the vacated spire is partitioned off by the formation of a thin nacreous plate; and its walls being thin and fragile, it is then broken away, as above described. In *Vermetus gigas*, the vacated portions of the tube are successively partitioned off, and a series of concave plates or septa developed; but the part of the shell thus divided into chambers, or "camerated," is retained. The *Spondylus varius*, among Bivalves, offers an analogous structure. In the pearly nautilus, the vacated portion of the shell is converted into a series of chambers by the development of calcareous septa in greater number and regularity than in any Gastropodous Univalves; and the partitions are perforated by a membranous tube or siphon, and the deserted chambers are converted, by the superaddition of this part, into a hydraulic machine, perfectly adapted to the habits and exigencies of the animal. The like structure, with various modifications, obtains in the extensive, but mostly extinct, race of "Siphoniferous" Cephalopods. In the argonaut, the vacated spire of the shell is not partitioned off, but is retained in full communication with the inhabited part, and made subservient to the reproductive economy of the species. In the *Magilus antiquus*, the posterior part of the shell, as it is deserted, is progressively filled up with a dense, solid, subtransparent crystalline deposit of carbonate of lime. A deposit of similar calcareous material, in a less degree, fills up the deserted spire of the shell in some species of *Cassis*, *Mitra*, *Triton*, &c.; and in the long "turreted" shells of the *Terebræ*, *Cerithiæ*, &c. the deposition of this dense material in the vacated apex is the preventative, instead of the cause, of decollation.

CO′NCLAVE. (Lat. con, *together*, and Gr. κλειω, *I shut up*.) The assembly of cardinals for the election of a pope. It begins the day following the funeral of the deceased pontiff. The cardinals are locked up in separate apartments, and meet once a day in the chapel of the Vatican (or other pontifical palace), where their votes, given on a slip of paper, are examined. This continues until two thirds of the votes are found to be in favour of a particular candidate. The ambassadors of France, Austria, and Spain have each the right to put in a veto against the election of one cardinal, who may be unacceptable to their respective courts.

CONCLU′SION. In Logic, that proposition which is inferred from certain former propositions, termed the premisses of the argument.

CO′NCORD. (Lat. concordia.) In Music, the relation of two sounds agreeable to the ear either in succession or consonance.

CONCO′RDANCE. (Lat.) A biblical index, in which all the leading words used in scripture are arranged alphabetically, and a reference made to the various places in which they occur, for the purpose of enabling the student to collate with facility one passage with another in the view of determining its meaning. The importance of this class of works was early appreciated, and a vast deal of labour has been expended in compiling them. Concordances have been made of the Greek Septuagint, the Greek Testament, the Latin Vulgate, and the English Old and New Testaments; a full list of which will be found in *Watt's Bibliotheca Britannica*, and in *Orme's Biblio. Biblica*. The first Concordance was compiled by Cardinal Hugues de St. Cher, who died in 1262. The best English Concordance is that of Cruden, which appeared in 1737, and still maintains its ground as an authority.

CONCO′RDAT. An agreement or convention upon ecclesiastical matters made between the Pope and some temporal sovereign, as that between Pius VII. and Bonaparte in 1802, by which the Roman Catholic religion was re-established in France; on which occasion the Pope recognized the new division of France into 60 sees, instead of the much greater number which had existed before the revolution, the payment of the clergy from the national revenues, and the appointment of the bishops by the

civil authority. Origiually the term was applied to agreements regulating mutual rights between bishops, abbots, priors, &c. The liberties of the French church were first established by the pragmatic sanctions of Saint Louis (1268), and Charles VII. (1439). In 1516 a concordat between Francis I. and Pope Leo X. divided the privileges of the church between them, and the king assumed the nomination of bishops. The states of Orleans restored their election to the chapters in 1560. The pragmatic sanctions were still considered as forming the base of ecclesiastical law in France down to the revolution.

CO'NCRETE. (Lat. concrescere, *to coalesce in one mass.*) In Architecture and Engineering, a mass composed of stone chippings or ballast cemented together through the medium of lime and sand, usually employed in making foundations where the soil is of itself too light or boggy, or otherwise insufficient for the reception of the walls. The employment of concrete in this country owes perhaps its introduction to Mr. George Semple, the engineer who erected the Essex bridge at Dublin, and who in 1776 published a Treatise on Building in Water; but there is no doubt it was well known at least to the Italian architects, if not to those of higher antiquity. The *riemputa* of Palladio, and the instructions in Alberti's 3rd Book, chap. viii., clearly point to what is now called concrete. The essential quality of concrete seems to be that the materials used should be of small dimensions, so that the cementing medium may act in every direction round them, and that the latter should on no account be more in quantity than is necessary for that purpose. Architects and engineers have much varied the proportions of lime and sand used. If the lime, which should be fresh and ground to powder, be good stone lime, such as that from Dorking, used in the neighbourhood of London, it will bear three or four times its measure by bulk of sand. These, and the ballast or gallots, as the stone chippings are called, should be thoroughly turned over and mixed together. If the foundations be wet, the mixture will want very little if any water; indeed sometimes the ballast only is wetted, and then covered over with the lime and sand. It is then filled into the barrows, and run on to be dropped from a stage into the foundations. This latter operation should be performed at as great a height as possible above the level of the trench, in order that the whole of the different particles of the composition may be compressed together so as to occupy the least possible space. The stones employed should not exceed the size of a common hen's egg. The mass very quickly sets and becomes extremely hard. On the top of it, which is kept as level as possible, a tier of what is called Yorkshire stone landings is laid, and very often throughout the lengths a chain of timber is buried in the footings, whose durability is requisite only while the work is settling; over the landings and timber thus laid, the latter, it is to be observed, occupying but a very small portion of the thickness of the footings, and quite buried in them, the walls are carried up.

CONCRETE TERM, in Logic, is so called when the notion derived from the view taken of any object is expressed with a reference to, or as in conjunction with, the object that furnished the notion; as "foolish," or "fool." When the notion is expressed without any such reference, it is called an abstract term; as "folly." (See *Whately's Logic*, p. 124.)

CONCU'SSION. (Lat. concutio, *I shake.*) A term generally applied to injuries sustained by the brain, independent of fracture of the skull, as from blows and falls. More or less insensibility, sickness, impeded respiration, and irregular pulse are the first symptoms; but these subside, and the sufferer often becomes more easy and collected; yet, although the symptoms apparently abate, dangerous inflammation may be going on, and a fatal termination ensue. In all accidents of this kind, where, as is commonly said, persons are *stunned*, the most cautious treatment should be adopted, and no time lost in obtaining skilful professional aid.

CONDENSA'TION. The rendering a body more dense, compact, or of greater specific gravity, by bringing its particles into closer union. The term is commonly applied to the conversion of vapour into fluid by distillation or otherwise. See GAS.

CONDE'NSER. An instrument for reducing an elastic fluid of a given mass into a smaller volume. The pneumatic condenser is a syringe by which a large quantity of air may be forced into a given space. It is constructed on the same principle as the air-pump; only the valves are disposed in the contrary order, that is, to open inward instead of outward.

CONDI'TION. In Law, has been defined in the most general sense, "A restraint annexed to a thing, so that by the non-performance the party shall receive loss, and by the performance advantage." It is most commonly used to signify a term whereon a grant is made: *e.g.* grant of an estate to A., on condition that the grantee shall pay such a sum on such a day, or else his estate shall cease. Conditions of this description may be implied by law: as, where tenant for life enfeoffs a stranger in fee simple, he forfeits his estate for the breach, as it is said, of the implied condition not to grant a greater estate than his own. Conditions are *precedent*, when an estate is gained on the performance of them; *subsequent*, when the condition is to be performed after the acquisition of the estate which is lost by its non-performance. But the distinctions between these two classes are numerous and minute. In general, where a condition is of such a nature that compensation can be made for its non-performance, equity will relieve the party breaking it from the consequences of the breach on making such compensation.

CONDI'TIONAL PROPOSITION, in Logic, is one which asserts the dependence of one categorical proposition on another: *e.g.* "If the wind changes, it will rain." The proposition from which the other results is termed the Antecedent; the resulting proposition the Consequent. A conditional syllogism is one in which the reasoning depends on a conditional proposition. It is of two sorts, constructive and destructive; as, 1. If A=B, then C=D; but A = B, therefore C = D. 2. If A=B, then C=D; but C is not equal to D, therefore A is not equal to B. The connection between the antecedent and consequent of a conditional proposition is termed the Consequence.

CONDOTTIE'RI. (It. *leaders.*) In Italian History, a class of mercenary adventurers in the 14th and 15th centuries, who commanded military bands, amounting to armies, on their own account, and sold their services for temporary engagements to sovereign princes and states. One of the earliest and most famous among those leaders was the Englishman Sir John Hawkwood, who commanded in various Italian wars about the time of our Edward III. The bands under command of the Condottieri were well armed and equipped. Their leaders had in many instances considerable military skill; but, as they took no interest in national contests, except to receive pecuniary advantages, the wars between them became a sort of bloodless contests, in which the only object of each party was to take as many prisoners as possible for the sake of the ransom. This singular system of warfare was only put an end to by the more serious military operations of the French, who invaded Italy under Charles VIII. Although many Condottieri acquired much honour as well as emolument, one only attained to high rank and independent power; this was Francesco Sforza, originally a peasant, who in 1451 made himself duke of Milan, and transmitted that sovereignty to his descendants.

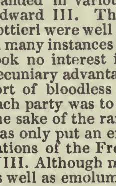
CONDU'CTOR. In Electricity. See ELECTRICITY.

CO'NDUIT. (Fr.) In Architecture, a passage of very narrow dimensions, usually subterranean, for the purpose of secret communication between apartments, many of which exist in ancient buildings. Also a pipe for the supply of water to any place.

CO'NDYLE. (Gr. κονδυλος, *a knuckle.*) The rounded head of a bone.

CONDY'LOPEDS, *Condylopoda.* (Gr. κονδυλος, and πους, *a foot.*) A name applied by Latreille to that subdivision of Encephalous articulate animals which have jointed feet: the Acephalous Cirripeds are excluded from this group, which consequently includes the Myriapods, Insects, Arachnidans, and Crustaceans.

CONE. In Geometry, a solid body, having a circle for its base, and terminating in a point, which is called its vertex. The cone may be described as follows: — Suppose a fixed point A without the plane of the circle B C D, and through the point A let a straight line A B indefinitely produced on both sides be drawn, and carried round the circumference of the circle B C D; the two surfaces A B C D and A *b c d* generated by this motion are the surfaces of two opposite or vertical cones. The circle B C D is called the *base* of the cone, and the straight line A O drawn from its vertex to the centre of the base is called its *axis*. If the axis is perpendicular to the plane of the base, the cone is said to be *right*; if the axis is inclined to the plane of the base, the cone is *oblique*. Some of the principal properties of the cone are the following:—The area or surface of a right cone, exclusive of its base, is equal to a triangle of which the base is equal to the periphery of the base of the cone, and altitude equal to the slant side of the cone; or equal to the sector of a circle whose radius is the side of the cone, and its arc equal to the circumference of the base of that solid. It is much more difficult to determine the surface of an oblique cone, which cannot be reduced to the measure of the sector of a circle. The solid contents of a cone, whether right or oblique, are equal to one third of a cylinder having the same base and altitude. The centre of gravity of a right cone is distant from the vertex $\frac{3}{4}$ of the axis. Sometimes the name cone is given to other solids than those whose surfaces are produced by the motion of a straight line about the circumference of a circle. It is applied generally to all bodies which can be formed in the same manner, assuming any curve whatever for the circumference of the base. The beautiful relation which connects the cone,



the sphere, and the cylinder, namely, that they are to each other in the proportion of 1, 2, and 3, was discovered by Archimedes.

CONE OF RAYS. In Optics, includes all the rays which fall from a luminous point, or from a single point of a luminous object, upon a given surface; for example, the object glass of a telescope.

CONFE'DERACY. (Lat. con, *together*, fœdus, *a league.*) In Politics, an alliance of independent states for a common object: sometimes also, but less properly, of individuals.

CONFEDERA'TION, THE GERMANIC, was formed at the congress of Vienna: the instrument by which it is constituted bears date June 8.1815. This union was framed to supply the want of the ancient imperial government, dissolved in 1806. The constituent members are thirty-four monarchical states and four free cities, which enter the confederation as equal and independent. The diet of plenipotentiaries, which forms the representative body of the league, is permanent, and sits at Frankfort-on-the-Maine. When this diet meets as a *general* assembly (plenum) six states, viz. Austria, Prussia, Bavaria, Saxony, Hanover, Wurtemberg, have four votes each; five other states three each; four two; the rest one; making seventy in all. But in the making of fundamental laws, admission of new members into the confederacy, and on religious questions, unanimity is required. In the *ordinary* assembly of the diet, the votes are so apportioned as to make only seventeen in all: this is the assembly in which propositions are discussed, which are decided without discussion in the plenum. This ordinary diet manages the general affairs of the confederation. Austria presides in both diets. The principal objects of the confederation are, the examination of disputes between its members; mutual protection; reciprocal assistance towards securing internal tranquillity; the establishment of constitutions of estates in all the states; the establishment of certain central courts of appeal; legal equality of Christian sects; an international community of civil rights in some points; and finally, the regulation of the condition of mediatized princes and states. *See* MEDIATIZATION.

CO'NFERENCE. In English Parliamentary usage, a meeting of certain delegated members of the two houses to discuss the provisions of a bill respecting which there is a disagreement between them; usually on the subject of amendments introduced by one and rejected by the other. The principal rules relating to conferences are, 1. That a conference must be demanded by that house which is in possession of the bill. 2. It is the privilege of the House of Lords to name the time and place at which the conference shall be holden. 3. The house which asks the conference must in its message clearly express the subject matter respecting which it is to be holden. 4. It is usual for the house desiring the conference to appoint a committee to draw up reasons to be offered in support of the measure which the house has adopted. These reasons are communicated by its managers (*i. e.* delegates) to those of the other house; and it is irregular for any member to go beyond these reasons, or to speak anything except by way of introduction to their delivery. 5. If the reasons alleged on both sides fail in producing agreement between the houses, what is termed a free conference is demanded; usually after two conferences have been holden without effect. In a free conference the managers are not tied down to follow a particular line of instructions (although they may have received such instructions from their house), but may discuss the provisions of the measure in a more liberal manner.

Conference has also been the frequent denomination of meetings of divines for ecclesiastical purposes. The conferences of Hampton Court (1604) and the Savoy (1660), between clergy of the church of England and Puritans and Presbyterians, are well known in English history. The annual meetings of Wesleyan preachers are styled conferences.

CONFE'SSION, AURI'CULAR (Lat. auricula, *ear*), is accounted by the church of Rome part of the sacrament of penance. It must be made to a priest, who is under solemn obligation not to reveal it; and must be of every mortal sin. The Roman Catholics cite several passages of scripture, particularly Matt. iii. 6., Acts xix. 18., and James v. 16., as indirectly establishing this usage; which, however, as an authorized practice of the church, does not appear to be older than about A.D. 1215. Confession is also prescribed by the Greek church. Among Protestants, the Lutherans for some time retained it; but confession to God alone is recognized in our church as preparatory to absolution. (See especially *Bingham, Orig. Eccl.* book xviii. c. 4.)

CONFESSION OF FAITH. A formulary setting forth the opinions held by a religious community. The most important documents of this nature published prior to the Reformation are the Apostles', the Nicene, and the Athanasian creeds. (See these arts.) Since that period the Romanists refer, 1. To the decrees and catechism of the council of Trent, as containing a complete exposition, accompanied by an elaborate defence, of their opinions; 2. To the Creed of Pius IV., published in 1564, which begins with a statement of the Nicene creed, and proceeds to declare briefly and explicitly the additional tenets of the Romish church; 3. The exposition of the Catholic faith by Bossuet, as having been sanctioned by the Pope, is considered of secondary authority.

The most authentic symbol of the Greek church is that which was drawn up in 1642 by Mogila, the metropolitan of Kiow. It was approved with great solemnity by the patriarchs and principal clergy of that communion.

The reformed churches have in almost all cases drawn up summaries of their peculiar tenets, and require their ministers to express their assent to them. The church of England requires subscription upon ordination to the Thirty-nine Articles, and the three articles of the 36th Canon which relate to the supremacy of the King, &c. The Book of Common Prayer and the Homilies are also authorized statements of the doctrine of this community.

The symbolic books of the Lutheran church are numerous: the principal are, the Confession of Augsburgh, drawn up by Melanchthon in 1530; the articles of Smalcald by Luther (1538); the Great and Little Catechisms of Luther (1529); and the Form of Concord (1579). The original symbol of the Scotch church is called the General Confession of the true Christian Faith, which was adopted by the King and nation, together with the Solemn League and Covenant, in 1581. A second was drawn up in 1660 by some of the principal ministers, in consequence of an order in parliament for that purpose. The Confession of the Westminster Assembly (in 1643) was declared in 1690 by an act of parliament to be the national standard of faith in Scotland.

In this country the imposition of formularies for subscription which are conceived in other than the words of scripture has frequently been made a ground of dissent and separation from the English church. The Presbyterians also and Independents have suffered many secessions upon this ground, which is maintained as a clear deduction from the Protestant principle of the right of private interpretation. It may be answered, that a church, like the Romish, which forbids private interpretation, might reasonably enough express its belief in the words of scripture, the meaning of which in its mouth would be sufficiently intelligible; but that a Protestant church, on the contrary, must paraphrase the language of the Bible to make itself understood, and that its alternative must be between a confession of this nature and none at all; and the impracticability of the latter course has been shown by the experience of several minor sects in this country and elsewhere.

CO'NFESSOR. (In Greek, ὁμολογητης.) In Ecclesiastical History, the title given to those who have undergone persecution for Christianity short of death. They were peculiarly honoured in the primitive church, together with the memory of those who had actually suffered (martyrs). *Cyprian*, Epist. 37. (See *Giescler's Eccl. Hist.* 1st Period, 2nd Division, ch. 3.)

CONFI'GURATION. In Astronomy, denotes the position which the planets occupy relatively to each other.

CONFIRMA'TION. The laying on of hands by the bishop, for the conferring of the grace of the Holy Spirit; a rite by which a person arrived at years of discretion takes upon himself the performance of the baptismal vow made for him by his sponsors. This ceremony is derived from the practice of the Apostles, of whom we read (Acts, viii. 16. xix. 16.) that after certain disciples at Samaria and Ephesus had been baptized, they laid their hands upon them, and the Holy Ghost came upon them. The descent of the Holy Ghost upon the Apostles themselves on the day of Pentecost is considered also as an example of confirmation succeeding baptism. In the early ages this ceremony seems to have been accompanied very generally with the unction of the forehead. This ceremony is retained by the Roman Catholics, who consider confirmation a sacrament.

CO'NFLICT OF LAWS. The opposition between the municipal laws of different countries, in the case of an individual who may have acquired rights or become subject to duties within the limits of more than one state. In the language of Mr. Burge (*Colonial and Foreign Law*, i. 5.), "the right or claim which is in contestation before a judicial tribunal may present a conflict between the laws of the country in which he was born, or had a domicile, or had taken up a temporary residence, or in which his property, the subject of the claim, was situated, or in which the act, instrument, or testament on which the claim is founded was executed, or in which the contestation takes place. In this conflict of laws it becomes an important branch of jurisprudence to ascertain which should be selected, and the principles on which the selection is to be made." The following are among the principal works on this subject: — *Rodenburg on the Conflict of Statutes*, an Essay appended to his treatise *De Jure Conjugum*; *Hortius, De Collisione Legum*; *Boullenois, De la Personnalité et de la Réalité des Lois*; the

American judge Story's treatise on the *Conflict of Laws;* and the above cited work of Mr. Burge, *Commentaries on Colonial and Foreign Laws generally, in their Conflict with each other and with the Law of England,* 4 vols. 8vo. Lond. 1837.

CO'NFLUENT. (Lat. confluens, *flowing together.*) Running together. Applied to eruptive diseases in which the pimples or pustules are not detached, but so numerous as to form confluent patches, or even to cover the whole surface of the body; hence the term *confluent small-pox.*

CONFO'RMITY, OCCASIONAL. The participation of one in any of the observances (more particularly sacraments) of a church from which he dissents. Much controversy existed among the English Dissenters, especially in the reign of Queen Anne, with respect to the lawfulness of occasional conformity.

CONGE'. (Fr.) In Architecture the same sort of moulding as the echinus or quarter-round; also a term used for the cavetto; the former being called the swelling congé, the latter the hollow congé.

CONGE' D'ELIRE. (Fr. *leave to choose.*) The king's writ or license to the dean and chapter to choose a bishop in the time of vacancy of the see; a mere formal proceeding.

CO'NGENERS. Species belonging to the same genus.

CONGE'STION. When there is an unnatural accumulation of blood in the capillary vessels of any part of the sanguiferous system, the organ in which it takes place, and the functions of which are disturbed, is said to suffer under *congestion:* it induces a morbid condition of the vessels of the part affected, which when once established is difficult of removal. Congestion of the brain, liver, or lungs is a frequent effect of fevers, though generally consequent upon a previous morbid condition of the organs.

CONGLO'MERATE. (Lat. conglomero, *I keep together.*) In Anatomy, glands which are made up of many small glands, the ducts of which unite into one, as the salivary glands, are so called. In Botany, the term is applied to flowers closely compacted upon one footstalk.

CONGLOMERATE. In Geology, a rock composed of pebbles cemented together by another mineral substance, either calcareous, silicious, or argillaceous.

CONGREGA'TION. (Lat. congrego, from con, *together*, and grex, *a flock.*) At Oxford and Cambridge the assembly of masters and doctors is so called, in which the ordinary business of giving degrees, &c. is transacted.

CONGREGATION. In Ecclesiastical language, properly an assembly of the people for the purpose of divine worship. Companies of religious persons, forming subdivisions of monastic orders, are styled in the church of Rome congregations. For an account of the congregations of cardinals at Rome, a species of committees for the transaction of business of the see of Rome, see *Enc. Metropol.* art. "Congregation." The "Congregation of the Lord" was an appellation assumed by the first Scotch Presbyterian Dissenters, in contradistinction to the Church of England, which they styled the "Congregation of Satan." They first came into notice in 1557, under the Duke of Argyle, and were at a later period led by John Knox.

CO'NGREGA'TIONALI'STS. A sect of Protestant Dissenters, who arose in this country as early as the reign of Queen Elizabeth, when Robert Brown maintained that every society of Christians meeting in one place for religious worship under its own laws and ministers formed a legitimate and independent congregation. The Congregationalists have been called from their founder Brownists, and in later times Independents. They form a powerful body in England, and are very numerous in America. Each congregation appoints its own ministers by vote, and can remove them at pleasure, and reduce them to the rank of laymen. They believe in the Trinity, predestination, total depravity, particular redemption, effectual grace and final perseverance; and maintain that every congregation of visible saints furnished with a pastor is under no other ecclesiastical jurisdiction whatever. (See *Neale's Hist. Puritans.*) The number of Independent congregations in England and Wales was stated in 1836 to be about 1840. (*M'Culloch's Statistical Account of the Br. Empire.*)

CO'NGRESS. (Lat. congredior, *I go together.*) In Politics, a meeting of the sovereigns of states, or their representatives, for the purpose of arranging international matters. The first general European congress was after the conclusion of the thirty years' war in Germany, at Münster and Osnabrück, 1648, which was followed by the peace of Westphalia. Remarkable general congresses have been — 1. of the Pyrenees, 1659; 2. of Aix-la-Chapelle, 1668; 3. Nimeguen, 1676; 4. Ryswick, 1697; 5. Utrecht, 1713; 6. Aix-la-Chapelle, 1748; 7. Teschen, 1779; 8. Paris, 1782; 9. Versailles, 1785; 10. the Hague, 1790; 11. Rastadt, 1797; 12. Erfurt, 1808; 13. Vienna, 1814, concluded at Paris, 1815; 14. Aix-la-Chapelle, 1818; 15. Troppau, 1820; 16. Laybach, 1821; 17. Verona, 1822.

CONGRESS is also the title of the national legislature of the United States of America. It consists of a house of representatives, and of a senate. The former is composed of members chosen every second year. The qualification of electors is the same with that required in their respective states for electors to the lower house in the state legislature. The number of representatives is apportioned according to the population of each state, and is altered every ten years, when the census is taken by authority. In making this estimate, the slave population is reckoned only at three fifths of its amount. There cannot be more than one representative for 30,000 free persons. The senate is composed of two members from each state: the senators are chosen for six years by the legislature of the state. The house of representatives chooses its own speaker: the vice-president of the United States is, ex officio, president of the senate. Bills for revenue purposes must originate in the house of representatives; but are liable to the proposal of amendments by the senate. The senate has the sole power of trying impeachments; but can only convict by a majority of two thirds of the members present, and its sentence extends only to removal from office and incapacitation for holding it. The regular meeting of congress is on the first Monday in December annually. Every bill which passes the two houses is sent to the president for approval or disapproval; in the latter case, he returns it, with his reasons, to the house in which it originated: if, on reconsideration, it is passed again by a majority of two thirds in each house, it becomes law. The powers of congress are strictly limited, and separated from those of the various state legislatures, by the constitution.

CO'NIC SE'CTIONS. In Geometry, lines formed by the intersections of a plane with the surface of a cone, which assume different forms, and acquire different properties, according to the different positions of the plane in respect of the axis of the cone. There are five species: —

1. If the cone be cut by a plane passing through its vertex, the common intersection of the conical superficies and the plane will be two straight lines meeting in the vertex.

2. If the intersecting plane be parallel to the base, or, in the case of the oblique or scalene cone, if it be so situated as to cut off from the vertex a cone similar to the original cone, the section will be a circle.

3. If the intersecting plane be parallel to a plane which touches the cone, the section will be a parabola.

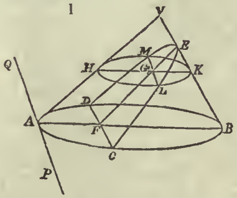
4. If the intersecting plane pass through both sides of the cone, and is neither parallel to the base nor to the plane of a subcontrary section, the section will be an ellipse.

5. If the intersecting plane have such a position that, when produced, it meets the opposite cone, the section is a hyperbola.

These five are the only lines which can be formed by the common intersection of a plane and the surface of a cone, and they all equally arise from that intersection; but as the straight line and the circle form the peculiar subject of elementary geometry, their properties are usually treated apart; and the three last, namely, the parabola, the ellipse, and the hyperbola, considered as the curves especially designated by the term *Conic Sections.*

Some of the principal and distinctive properties of the curves are easily deduced from this mode of generation.

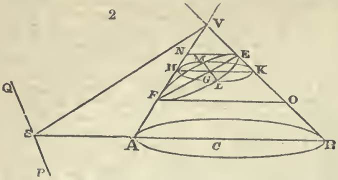
1



Let V A C B be the cone, and C D E the section made by a plane parallel to the plane which touches the cone in the line VA; then, by the definition, C E D is a parabola. Now let P Q be the intersection of the plane which touches the cone in V A with the plane of the base A C B; then P Q being a tangent to the circle A C B D, is perpendicular to A B, the diameter of that circle, and consequently C D, which is parallel to P Q, is also perpendicular to A B; therefore C F is equal to F D. In F E take any point G, through which let there pass a plane H L K, parallel to the base A C B, intersecting the plane C E D in the straight line L G M; then L M will be parallel to C D, and perpendicular to H K, and L G equal to G M. We have therefore, from the property of the circle, $CF^2 = AF \cdot FB$, and $LG^2 = HG \cdot GK$; therefore since by reason of the parallels V A and E F the line A F is equal H G, $CF^2 : LG^2 :: FB : GK$. But $FB : GK :: EF : EG$; therefore $CF^2 : LG^2 :: EF : EG$; consequently, since C F and E F are constant quantities, the ratio of LG^2 to E G (or of LM^2 to E G) is constant; whence we infer that in the parabola the square of any ordinate L G is equal to the rectangle of the corresponding absciss E G into a constant quantity. From this all the other properties of the curve may be deduced. It is in fact the common equation of the parabola. *See* PARABOLA.

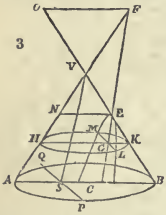
For the ellipse and hyperbola, let E M F L be the section; through V draw a plane parallel to E M F L, and

2



let P Q be its intersection with the plane of the base. Through C, the centre of the base, draw C S perpendicular to P Q, meeting the base in A and B. Let E F be the intersection of the plane E L M with the plane A V B, which passes through the axis of the cone; and in E F take any point G, through which let a plane H M K L be drawn parallel to the plane of the base, the line L M being its intersection with the plane E L M. Lastly, through the points E and F let E N and F O be drawn, meeting the opposite sides of the cone in N and O. Because of the similar triangles, we

3



have E G : G K : : E F : F O,
and F G : G H : : F E : E N,
therefore E G·G F : G K·G H : : E F^2 : F O·E N.

Now E F^2 and the rectangle F O·E N are constant quantities, independent of the position of the point G; and G K·G H = G L^2 (L M being parallel to P Q, and therefore perpendicular to H K); consequently the rectangle E G·G F is to the square of G L in a constant ratio. This property furnishes an equation to the ellipse and hyperbola, from which all the properties of those curves may be deduced. *See* ELLIPSE and HYPERBOLA.

The mutual relations of all the curves to each other may be rendered sensible by supposing the plane V P Q to revolve about an axis passing through V parallel to P Q, and the intersecting plane E M L to accompany it in its revolution, always maintaining its parallelism. Suppose the revolution to commence when the plane V P Q is parallel to the base; in this position the intersection of the cone with E M L is a circle. When V P Q changes its position, and becomes inclined to the plane of the base, the section E M F L (*fig.* 2.) becomes an ellipse. As the plane V P Q continues to revolve, the ellipse becomes more and more elongated, till at length P Q touches the plane of the base (*fig.* 1.), when the curve, instead of returning into itself, exhibits two infinite branches, and passes into the parabola. The revolution continuing, the line P Q falls within the base of the cone (*fig.* 3.); the section E M L still presents infinite branches, but its axis E G now meets the opposite cone in F, the vertex of another section entirely similar and equal to E M L; whence the hyperbola has two pairs of branches, which, from the opposite cones, are called opposite hyperbolas. Suppose that in this position (while P Q falls within the base) the distance between the two planes V P Q and E M L is diminished; as the distance diminishes the curvature of the hyperbolic branches will also diminish; and when the distance vanishes the curvature vanishes, and the two branches pass into a system of two straight lines intersecting each other in the apex of the cone.

The sections of the cone were first studied by the geometricians of the school of Plato. They admitted, however, only the right cone into their geometry; and they supposed the section to be formed by a plane perpendicular to its side. Consequently the three sections were formed from three different cones, the angles at the vertex being right, acute, or obtuse. The parabola was produced from a right-angled cone, the ellipse from an acute-angled cone, and the hyperbola from an obtuse cone. Apollonius of Perga, according to Eutocius, was the first who showed that the three sections may be obtained from every cone, whether right or oblique, and whatever the the angle of its apex, the species of the curve depending on the different inclinations of the plane of the section to the cone itself. It has, however, been established that Archimedes, who flourished about forty years prior to Apollonius, was acquainted with the fact that the three sections may be derived from the same cone. Pappus, in his Mathematical Collections, ascribes to Apollonius the names by which the three sections are designated: the term *Parabola*, however, occurs in the writings of Archimedes.

Although the three curves were first noticed as resulting from the sections of the cone, they still decidedly belong to plane geometry; and their genesis may be defined, and all their properties investigated, without having any reference whatever to the solid. Accordingly many geometers, in modern times, have treated the curves as generated by the motion of points on a plane; and this method has undoubtedly the advantage of relieving the student from the difficulty of conceiving the positions and intersections of different planes, and following out the relations of the lines drawn on them, which become so complicated when represented on the same surface. Dr. Wallis of Oxford, and the celebrated De Witt, seem to have been the first who adopted this method, which has been followed by Dechales, De La Hire, Boscovich, Dr. Simson, and many others. The ancient mode of defining them from the sections of the cone is seldom adopted in the recent treatises.

Various definitions of the curves *in plano* have been proposed. The parabola is usually defined from this property, that the distance of any point in the curve from the focus is the same as its distance from the directrix. For the ellipse and hyperbola the property which has been most generally assumed as the definition is, that if any point be taken in the curve, and straight lines be drawn from it to the two foci, the sum of those lines in the case of the ellipse, and their difference in the case of the hyperbola, is a constant quantity. This property seems to have been chosen rather from considerations respecting the facility of the description of the curves by mechanical means, than from any peculiar advantage which it affords for the investigation of their other properties. It does not indicate the relationship of the three curves, and is in fact not applicable to the parabola, which has only one focus. On this account Boscovich selected a property which gives a definition applicable alike to all the three sections, and from which the general properties common to all of them are established by the same demonstration. It is this — a point and a straight line being given by position on a plane, another point which moves in such a manner in the same plane that its distance from the given point has to its distance from the given straight line a constant ratio, describes a conic section. When the constant ratio is a ratio of equality, the curve traced out by the moving point is a parabola; when a ratio of minority the curve is an ellipse, and when a ratio of majority an hyperbola. This general definition of the conic sections has also been adopted by Thomas Newton, Walker of Nottingham, and Professor Leslie, in their respective treatises.

The different properties of the conic sections may also be investigated by the modern algebraic analysis; and as all the curves are derived from the same cone, so all their equations are included in one general equation, of the second degree, between two variables. The equation of the second degree between the two variables x and y, in its most general form, is

$$A y^2 + B x y + C x^2 + D y + E x + F = 0,$$

which, by assigning certain values to the constant coefficients A, B, C, D, E, F, or assuming certain relations to exist among them, becomes the equation of an ellipse, an hyperbola, a parabola, a circle, or that of a system of two straight lines; and it may be demonstrated that whatever be the values of the coefficients, it can only express one or other of those curves. See *Biot's Essai de Géometrie Analytique; Hamilton's Analytical System of the Conic Sections;* or the *Traité Analytique des Sections Coniques, &c.* by the Marquis de l'Hopital.

The conic sections have acquired a remarkable interest in modern times on account of their use in natural philosophy and astronomy. A body projected in space, and urged by a central force which varies inversely as the square of the distance, must describe a conic section; and all the planets move in ellipses about the sun. The knowledge of the properties of the ellipse doubtlessly facilitated the discovery of the true nature of the planetary orbits; and hence it has been said, with some appearance of truth, that to the seemingly barren speculations of the Greeks relative to the sections of the cone we are indebted for the sublime theories of Kepler and Newton. A considerable number of the most interesting properties of the curves are demonstrated in the first Book of the *Principia*, where Newton has considered the method of solving this problem — Straight lines and points being given by position on a plane, to describe a conic section which shall pass through the given points and touch the given straight lines.

Treatises on the conic sections are exceedingly numerous; in fact there is no part of the mathematics which has been more studied by geometricians, both ancient and modern, than the properties of these curves. To the ancients they furnished an excellent field for the exercise of their elegant geometrical analysis; and the more difficult investigations of series for their quadrature and rectification have given occasion to some of the most elegant applications of the modern calculus. The following are some of the principal geometrical treatises — *Apollonii Pergæi Conicorum Libri Octo*, &c., Oxford,

1710, by Dr. Halley; Viviani's two works — 1. *De Maximis et Minimis Geometrica Divinatio*, 2. *De Locis Solidis Secunda Divinatio Geometrica; De La Hire's Sectiones Conicæ*, Paris, 1685; *Hamilton, De Sectionibus Conicis Tractatus Geometricus*, Dublin, 1758; *Simson's Treatise*, in Latin and English; *Robertson's* ditto; *A short Treatise on the Conic Sections*, by the Rev. T. Newton, Cambridge, 1794; *Walker's Treatise*, London, 1794; *Leslie's Treatise on Lines of the Second Order; A Geometrical Treatise on the Conic Sections* by Professor Wallace, Edinburgh, 1837, &c. &c.

CONI'DIA. (Gr. κονις, *dust*.) A term sometimes used in describing lichens, to denote the bodies which constitute the powdery matter called *soredia*, lying upon the surface of the thalli. By others they are called the *propagula*.

CONI'FERÆ. (Lat.) In Botany, a natural order of arborescent or shrubby Gymnosperms, inhabiting most parts of the world, and usually both resinous and evergreen. Their real organization was, for a long period, but little understood, until Brown discovered that the ovules of the entire order are naked. No other race of plants can be named of more importance to mankind than this, — first, for their resinous secretions, as turpentine, pitch, Canada balsam, &c.; and secondly, for their timber, which is used under the names of fir, pine, deal, cedar, sandarach, and many others. All the kinds of fir, cedar, juniper, pine, savin, cypress, and arbor vitæ, are species of genera belonging to this order, which appears from geological evidence to have existed in great abundance among the earliest vegetation that clothed the surface of our planet.

CONIRO'STERS, *Conirostres*. (Lat. conus, *a cone*, and rostrum, *a beak*.) A tribe of Insessorial birds or perchers, including those which have a thick robust conical beak, as the crows and finches.

CONISTE'RIUM. (Gr. κονιστηριον.) In Ancient Architecture, a room in the gymnasium and palæstra, wherein the wrestlers, having been anointed with oil, were sprinkled over with dust, that they might lay firmer hold of their antagonists.

CO'NITE. (Gr. κονις, *powder*.) A silicious carbonate of lime, found associated with certain zeolites, in the form of a white powder.

CONJOINT DEGREES. In Music, a term used of two or more notes which immediately follow each other in the order of the scale.

CONJOINT TETRACHORDS. In Music, two tetrachords or fourths, in which the same note is the highest of one and the lowest of the other.

CONJUGA'TION. (Lat.) In Grammar, is to verbs what *declension* is to substantives — the sum total of the inflexions which they admit, corresponding to the various circumstances of time or mood under which an action is conceived to take place.

CONJU'NCTION. In Grammar, that part of speech which expresses the relation of propositions or judgments to each other. *See* GRAMMAR.

CONJU'NCTIVE MOOD. That modification of the verb which expresses the dependence of the event intended on certain conditions. *See* GRAMMAR.

CONNARA'CEÆ. (Connarus, one of the genera.) In Botany, a natural order of shrubby or arborescent Exogens inhabiting the tropics, and only distinguished with certainty from *Leguminosæ* by the radicle being remote from the hilum: they approximate very closely to the Cæsalpineous section of *Leguminosæ*; but their want of stipules and regular flowers will usually be sufficient to distinguish them from the great mass of the Papilionaceous section.

CONNI'VENT. (Lat. conniveo, *I wink*.) A term used figuratively by botanists in describing the direction of organs, to denote a gradual inward direction, as in many petals. It is the same as converging.

In Anatomy, the term is applied to those valvular folds of the lining membrane of canals which are so disposed as to retard, while at the same time they permit, and, as it were, connive at, the passage of the contents of such canals as the "valvulæ conniventes" in the human intestine.

CO'NNOISSEU'R. (Fr. connoitre, *to know*.) In the Fine Arts, one who is versed in a knowledge of the fine arts. His qualifications are so numerous, that very few sound connoisseurs have appeared; and in nine cases out of ten these come under the description of a well-known Italian author of being "conoscitori senza cognizione."

CONOHE'LIX. A genus of shells, intermediate beween the *Cones* and *Volutes*.

CO'NOPS. (Gr. κωνωψ, *a gnat*.) A Linnæan genus of Dipterous insects, characterized by having an elongated, slender, pointed proboscis. It is at present subdivided into the genera *Bucentes*, *Prosena* and *Stomoxys*, *Myopa*, *Zodion*, and *Conops* proper: the larvæ of the latter subgenus are developed within the abdominal cavity of the humble bees, and other Hymenoptera.

CONSCIENCE, COURTS OF, and of REQUESTS, are courts for the recovery of small debts. The jurisdiction of these courts in London and other places arises out of various statutes, beginning with 1 J. I. c. 14., their original appointment having been by order in council under Henry VIII. The jurisdiction of the London Court of Conscience is extended by 39 & 40 G. III. c. 104. to the recovery of debts not exceeding 5*l*., and in Southwark and many other places by subsequent statutes.

CO'NSCRIPT. (Lat. conscribo, *I enroll together with others*.) *Patres Conscripti*, or *Fathers Conscript*, A title of the Roman senators; properly of those who were added to the senate subsequently to the expulsion of the kings.

CONSCRI'PTION. The compulsory enrolment of individuals for military or maritime service, taken from the population at large. The conscription, in the Roman commonwealth, was made not by lot, but by arbitrary selection by the consuls from among the bulk of the citizens when a levy was required. In France the conscription was established during the revolution, before which period the armies of that country had been recruited by voluntary enlistment. The word is first used in a law of 1798. According to the law as at present established, all citizens are liable to the conscription at the age of twenty. Each arrondissement has its contingent allotted to it out of the total number required for the service, and this number is filled up by lot from the youths liable to the conscription. There are, however, various claims for exemption recognised by the law. The legal duration of the service is seven years.

CONSECRA'TION. (Lat. sacer, *holy*.) The act of setting apart a person or thing to the service or worship of God: thus a newly built church is consecrated with certain ceremonies, varying in different communities. The admission of a bishop to his office is called his consecration.

CONSE'NTIAN GODS. A term by which the Latins distinguished their twelve chief deities — Juno, Vesta, Minerva, Ceres, Diana, Venus, Mars, Mercury, Jupiter, Neptune, Vulcan, and Apollo. The origin of these deities was Italian, and distinct from those of the Greeks; but as the literature of Rome took its tone and colour from Greece, so its mythology was mixed up with that of the latter country, those deities whose functions most resembled each other being confounded, till the above names became regarded as nothing more than the Latin appellations of the Greek divinities.

CONSE'RVATORY. In Horticulture, is a glazed structure, in which exotic trees and shrubs are grown in a bed or floor of soil. It is distinguished from an orangery by its having a glazed roof, while that of the latter is opaque; and from a greenhouse by the plants being planted in the free soil, and thus growing up from the floor, while in the greenhouse the plants are grown in pots placed on shelves, or on a stage or series of shelves, rising one above another. Above a century ago, for example, in the time of Evelyn, the term conservatory was applied to those garden buildings now called orangeries, and in modern horticulture employed only for the preservation of exotic plants, such as orange trees, &c., which are in a dormant state during winter. The greenhouse and the modern conservatory were then not in existence. They are exclusively employed for the preservation of plants which are in a growing state during winter. The largest conservatory in the world, at the present time (1841), is that erected at Chatsworth in Derbyshire, for palms and other tropical plants, which covers above an acre of ground, and is sixty feet high. There are very handsome conservatories for Cape and Australian plants at Alton Towers, and other places.

CONSIDERA'TION. In Law, is the material cause of a contract, without which it is not binding on the party. Consideration is said to be either expressed or implied. An express consideration is where the motive or inducement of the parties to the contract is distinctly declared by its terms; as where a man bargains to sell his land for 100*l*. It is implied, where an act is done, or a legal demand forborne, at the request of another, without an express stipulation: in which case, the law presumes an adequate compensation for the act or forbearance to have been the inducement of the one party, and the offer of the other; as where a person comes to an inn and makes use of it, intention to pay for the accommodation is presumed. Consideration is also either "valuable," that is, for money or an equivalent; or it is "of natural affection," certain degrees of relationship affording in some cases sufficient consideration for a gift.

CONSI'STORY. (Lat. consistorium, said to have been the private councillors of the Roman emperors.) An assembly of ecclesiastical persons; also certain spiritual courts are so called which are holden by the bishops in each diocese. At Rome the consistory denotes the judicial court constituted by the college of cardinals. The representative body of the reformed church in France is styled Consistory; a title and assembly originated by Calvin. There is now, or should be, according to law, a consistory for every 6000 Protestant souls, consisting of the pastor or pastors, and from 6 to 12 elders. The consistory names the pastor. There are now 88 reformed

consistories in France (not including the Lutheran churches).

CONSI'STORY COURT. The chancellor of every archbishop and bishop is the judge of this court in England, and a commissary is appointed for places remote from the consistory. *See* ECCLESIASTICAL COURTS.

CO'NSOLE. (Ital.) *See* ANCONES.

CONSO'LIDATED FUND. Down to 1816, the exchequers of Great Britain and Ireland were kept separate, certain portions of the public revenue arising in each kingdom being especially appropriated to the discharge of the interest on its own debts, and other peculiar purposes. But on January 5th, 1816, the separate exchequers were consolidated into one; and an act was at the same time passed consolidating certain portions of the joint revenue of Great Britain and Ireland into one fund, hence called the Consolidated Fund, and providing for its indiscriminate application to the payment of the public debts, civil lists, and other specified expenses of both kingdoms. Some portions of revenue are not included in this fund; but it embraces by far the largest part of the public income. Thus, in 1838, of a total nett income of 47,333,460*l.*, the consolidated fund included no less than 44,144,438*l.*: the expenditure on account of the peculiar charges to be defrayed by the fund during the same year amounted to 31,742,918*l.*, leaving a surplus of 12,401,570*l.* applicable to other objects. (*Fairman on the Funds*, 7th ed. p. 196.; *Parl. Paper*, No. 149. Sess. 1839, &c.)

CO'NSONANCE. (Lat. consonans, *sounding together*.) In Music, the agreement of two sounds simultaneously produced, the one grave and the other acute.

CONSONANT. *See* LETTER, VOWEL.

CO'N SORDI'NI. (Ital.) In Music, a direction to perform the passage, if on a pianoforte, with the dampers down, or on a violin with the mute on; it is usually written short, C. S.

CONSPIRACY. (Lat. conspiratio, *agreement*.) In Law, is in the strictest sense an agreement of two or more persons falsely to indict one, or procure him to be indicted, for felony; who, after acquittal, may have his writ of conspiracy. In a more general sense, many species of combinations to injure another are termed conspiracies; as to procure one to be arrested, to defraud under certain circumstances, &c. Conspiracy is an indictable offence; and two at least of the persons indicted must be found guilty to produce a conviction, as otherwise the offence is not proved against any one. Combinations of workmen to regulate the rate of wages, prior to the 6 G. 4. c. 129., were commmonly termed conspiracies.

CO'NSTABLE. A high officer in the monarchical establishments of the middle ages. (Lat. comes stabuli, *count of the stable*.) In France, the first dignitary under the crown, commander-in-chief and supreme military judge. In that country the office was abolished in 1627, as conferring powers too dangerous in the hands of a subject. In England the last permanent lord high constable was Edward Stafford, Duke of Buckingham, whose office was forfeited to the crown by his attainder in 1522; since which time it has only been occasionally conferred on particular emergencies. The title is supposed to have originated in the Lower Empire. (*Ducange*, *Gloss.*)

CONSTABLE. A constable is an officer particularly charged with the preservation of the peace, either within the hundred, where he is called high constable, or within the parish or tything, where he is called petty constable, and where he has generally superseded the tything-man. The duties of the high constable respecting the preservation of the peace are now merely nominal; but he is still of use to represent the hundred in certain legal actions, and to perform certain ministerial offices connected with the administration of justice, as, for instance, the return of jurors, which originally devolved upon the bailiff of the hundred. The functions of petty constable are still of great and daily importance. It is his business, in the first place, to interfere upon his own authority, and if necessary by apprehension of the offender, whenever a breach of the peace or other more serious offence is committed in his presence, or whenever he has sufficient information of a felony; and, in the next place, to execute all such warrants apparently and upon the face of them legal as shall be committed to his hands by competent authorities. He has a right, when impeded in the execution of his duty, to call upon bystanders for assistance, and has the power in case of sickness or disability to appoint a deputy to execute warrants in his stead. Constables were anciently appointed, and still might legally be so, by the jury of the leet; but high constables are now appointed either at quarter sessions or by the justices of the hundred out of sessions, and petty constables are annually sworn in to the office at quarter sessions for each parish upon presentment of the vestry; and the person so presented is compellable under the penalty of fine and imprisonment, except in recognized cases of disability or exemption, to serve the office. A *special* constable is a person appointed to act as constable upon a particular occasion; and any two magistrates have, in case either of actual or apprehended riot, the power of calling upon all persons who would be liable to serve as petty constables to act as special constables, and their refusal is punishable in the same manner as in the case of the former office. Constables are frequently appointed in pursuance of particular acts of parliament, as the police constables in London. (*Burn's Justice*, tit. "Constable;" *Viner's Abridgment.*)

CONSTELLA'TION. (Lat. con, *together*; stella, *a star*.) In order to distinguish with greater facility the different stars, it has been the practice of observers, from time immemorial, to separate them into groups or clusters, which have received the name of *constellations*, and been represented by the figures of men or animals, or other sensible objects to which they were fancied to have some resemblance. Hipparchus called them *Asterisms*; Aristotle and Hyginus, *Bodies*; Proclus, *Animals*; others, *Meteors*; but the term Constellation has been long established by general usage. The origin of these figures and names is involved in impenetrable obscurity. By most authors the twelve constellations of the zodiac are supposed to have been established about 1700 years before our era, either by the Egyptians or the Chaldeans. Dupuis supposes them to have had an incomparably more ancient origin, and that their names are significative of the climate of Egypt at the epoch when the solstice was in Capricorn; that is, about 15,000 before Christ. But even on this hypothesis, namely, that the names of the zodiacal constellations, or *signs*, as they are frequently called, are significative of the seasons, it may be supposed that reference was made to the sign opposite to the sun, instead of that which the sun occupied; in which case the origin of the names would be referable to an epoch preceding our era by about 2000 or 3000 years. This arises from the motion of the equinoctial points, which regress or go backward annually among the stars, accomplishing half a revolution in about 12,500 years.

Hipparchus was the first who constructed a catalogue of the stars from exact observations. It has been preserved to our own times in the *Almagest* of Ptolemy, and contains 1022 stars, distributed among 48 constellations; namely, 12 in the zodiac, 21 to the north of the zodiac, and 15 to the south. Stars which were not comprehended in any of the constellations (and it is evident that there must be many such) were called by a Greek term signifying *unformed*; that is, not entering into the *forms* of the constellations. Several have been added in modern times, as the stars of the southern heavens became better known. A much better idea may be formed of the figures and relative positions of the constellations by inspecting a common celestial globe, than from any description, however detailed.

The 48 constellations of Hipparchus are as follows:—

In the zodiac 12 — *Aries*, *Taurus*, *Gemini*, *Cancer*, *Leo*, *Virgo*, *Libra*, *Scorpio*, *Sagittarius*, *Capricornus*, *Aquarius*, *Pisces*.

In the northern hemisphere 21 — *Ursa Minor* (the Little Bear), *Ursa Major* (the Great Bear), *Draco* (the Dragon), *Cepheus*, *Bootes*, *Corona Borealis*, *Hercules*, *Lyra*, *Cygnus* (the Swan), *Cassiopeia*, *Perseus*, *Auriga* (the Waggoner), *Ophiucus* or *Serpentarius*, *Serpens*, *Sagitta* (the Arrow), *Aquila* (the Eagle), *Delphinus* (the Dolphin), *Equuleus* (the Horse's Head), *Pegasus*, *Andromeda*, *Triangulum* (the Triangle).

In the southern hemisphere 15 — *Cetus* (the Whale), *Orion*, *Eridanus*, *Lepus* (the Hare), *Canis Major* (the Great Dog), *Canis Minor* (the Little Dog), *Argo* (the Ship), *Hydra*, *Crater* (the Cup), *Corvus* (the Crow), *Centaurus*, *Lupus* (the Wolf), *Ara* (the Altar), *Corona Australis* (the Southern Crown), *Pisces Australis* (the Southern Fish).

To the above 48 constellations of Hipparchus, 12 near the south pole were added by Bayer, and represented in his *Uranometria*, the first edition of which appeared in 1603. These were, *Indus* (the Indian, or Indian Triangle), *Grus* (the Crane), *Phœnix*, *Apis* or *Musca* (the Bee), *Triangulum* (the Southern Triangle), *Avis Indica* (the Bird of Paradise), *Pavo* (the Peacock), *Pica Indica* (the Toucan), *Hydrus* (the Hydra), *Dorado*, *Piscis Volans* (the Flying Fish), *Chameleon*. The two constellations, *Coma Berenices* (Berenice's Hair) and *Antinous*, were formed by Tycho Brahé; the first comprehending some of Ptolemy's unformed stars near *Leo*, and the second of others near *Aquila*. They are given in the catalogue of Riccioli, published in his *Astronomy Reformed* in 1665.

In the *Planisphærium Stellatum* of Bartschius, published in 1624, the eight following constellations are found, and said to have been formed by the moderns in that part of the heavens which is visible in Europe — *Camelopardalis* (the Giraffe), *Tigris*, *Jordanus*, *Vespa* (the Wasp), *Columba Noachi* (Noah's Dove), *Monoceros* (the Unicorn), *Rhombus* (the Rhombus or Rhomboid), *Gallus* (the Cock). The same constellations are met with in the Celestial Charts of Royer, published in 1679, with the exception of *Gallus*. *Vespa* is also changed into *Lis* (the Flower-de-luce), and *Crux* (the Cross) added.

In the Charts of Hevelius, entitled *Firmamentum Sobiescianum*, and published in 1690, we find 10 new constellations — *Canes Venatici* (the Greyhounds, Asterion, and Chara), *Lacerta* (the Lizard), *Leo Minor* (the Little Lion, in place of *Jordanus*, mentioned above), *Lynx* (instead of *Tigris*), *Sextans* (the Sextant of Urania), *Scutum Sobiescianum* (Sobieski's Shield), *Triangulum* (the Little Triangle), *Vulpecula et Anser* (the Fox and Goose), *Cerberus*, and *Mons Mœnalus*.

To the above *Cor Caroli* (the Heart of Charles II.) was added by Flamsteed, and *Robur Carolinum* (the Oak of Charles) by Halley.

Notwithstanding the additions already made to the constellations in the southern hemisphere since the time of Ptolemy, Lacaille found so many clusters of unformed stars, while observing at the Cape of Good Hope, that he added to the list no fewer than 14 new constellations, to which he gave the following names — *Officina Sculptoria* (the Sculptor's Workshop), *Fornax Chymica* (the Chemical Furnace), *Horologium* (the Clock), *Reticulus Rhomboidalis* (the Rhomboidal Net), *Cœlum Scalptorium* (the Graver), *Equuleus Pictoris* (the Painter's Easel), *Pyxis Nautica* (the Mariner's Compass), *Octans Hadleianus* (Hadley's Octant), *Machina Pneumatica* (the Air Pump), *Circinus* (the Compass), *Quadra* (the Square), the *Telescope*, the *Microscope*, and *Table Mountain*. Some still more recent additions have been proposed, particularly by Bode; among which are the *Honours of Frederic*, the *Sceptre of Brandenburg*, *Herschel's Telescope*, &c.; but they do not seem to be generally used in astronomical catalogues.

If the question were to be asked, What good purpose can be served by this multiplication of arbitrary divisions and fantastic names? we apprehend that no very satisfactory answer could be given. Astronomers doubtless find it convenient to classify the stars under certain divisions; but when the number of divisions becomes so great as to be remembered with difficulty, the advantage disappears. The arbitrary nature of the divisions also leads to great inconvenience, inasmuch as they are liable to much uncertainty, and frequent change of boundary. Not only have the names in several instances been changed, but it seems to have been a common practice with astronomers and chart-makers to take stars from one constellation and give them to another, without any other rule than that of pleasing their own fancies. On this account it is frequently extremely difficult to identify stars (particularly in the southern hemisphere) in the different catalogues. It is to be wished that the whole of the constellations (excepting perhaps the 48 of Hipparchus and Ptolemy) were obliterated from our celestial charts and globes, and that observers in describing the places of the stars would confine themselves to a simple statement of their right ascensions and declinations, at least until some better arrangement and nomenclature shall have been devised and agreed upon.

CONSTI'TUENT ASSEMBLY. In French History, the first of the national assemblies of the revolution; elected in 1788 as the states-general, dissolved in 1791 after proclaiming the constitution of that year.

CONSTITU'TION. The collective body of the fundamental laws of a state; either contained in written documents, or established by prescriptive usage. Constitutions have been divided into three kinds by political writers: — 1. Those granted (octroyées) by monarchs to their subjects; 2. Those springing out of rights enjoyed independently by the people, or classes of the people, which in monarchical countries are recognised by the sovereign in his contract with the people; 3. Those founded on compact between sovereign powers, *i.e.* federal constitutions. In a certain sense, all states in which the power of a sovereign over his people, or classes of his people, is limited by law or legal usage in any particular, may be said to possess pro tanto a constitution; but, in ordinary language, only a government in which the power of legislation, or that of granting and withholding supplies to the sovereign, is vested in the people, or a body of representatives elected by them or by a class of them, is termed constitutional. Constitutions have again been divided into — 1. Those in which legislative power is exercised directly by the people (as in some small modern commonwealths, and in all the free states of antiquity); and, 2. Representative constitutions. The last again, as prevailing in modern Europe and America, has been divided historically into — 1. Those which have originated from compact between several independent interests, as the sovereign, clergy, nobles, and commons, in feudal kingdoms; 2. Those formed artificially, in modern times, on the model of the British constitution; which, although arising out of the same causes which produced the feudal constitutions, assumed in the course of time a different and more comprehensive character.

CONSTITU'TIONS. In Roman Law, decrees of regular authorities, as prætors, &c.; more particularly decrees of the emperors, whether by decree, edict, or letter.

CONSTITUTIONS, APOSTOLICAL. An ancient code of regulations respecting the doctrine and discipline of the church, said by some to have been promulgated by the Apostles, and collected by Clemens Romanus. They appear to have been at one time admitted into the canon of Scripture. Their authenticity has been a subject of much dispute. They have been printed together with the so-called Canons of the Apostles. (See *Cotelerii Patres Apostolici*, vol. i.; *Krabbe's Dissertations on the Apostol. Constitutions and Canons*, Hamb. and Gotting. 1829; *Gieseler, Eccl. Hist.* 1 Period, 3 Div. § 66.)

CONSTRI'CTOR. (Lat. constringo, *I squeeze*.) A name applied to the larger serpents, which overcome and destroy a struggling prey by throwing themselves round it in overlapping folds, and crushing it by their muscular force. The *Boa Constrictor*, properly so called, is a native of South America, having anal hooks, and a single row of subcaudal scutæ.

CONSTRU'CTION. (Lat. con, *with*, and struo, *I pile up*.) In Architecture, literally the building up from the architect's designs; but amongst architects it is more particularly used to denote the art of distributing the different forces and strains of the parts and materials of a building in so scientific a manner as to avoid failure and ensure durability.

CONSTRU'CTION OF EQUATIONS, in Algebra, is the representing of the roots of equations by means of the intersections of geometrical lines. The roots of any algebraic equation may be represented by the intersection of a straight line with a curve of the same dimensions as the proposed equation, the roots of the equation being the ordinates of the points of intersection. An equation of any degree may also be constructed by means of two curves, whose dimensions, multiplied together, produce the dimensions of the given equation. Thus, a quadratic equation may be constructed by the intersection of a straight line with a circle, or with any conic section; a cubic equation by the intersection of a straight line with a line of the third order; a biquadratic by the intersection of a straight line with a line of the fourth order, or by means of two conic sections.

CO'NSUBSTA'NTIA'TION. The term by which Luther expressed the opinion which he held upon the nature of the elements in the Eucharist, as distinguished from Transubstantiation, the doctrine of the Romanists. The latter assert, as the word they use implies, that the bread and wine are changed into the body and blood, and lose their former substance, although they retain its appearance miraculously to the senses. The Lutherans deny this change; but affirm that while the bread and wine do still remain in their natural substance, the body and blood are at the same time transfused into them, and thus that both are actually partaken of together. Calvin says, "I assert that the body of Christ is really (as the usual expression is), that is, truly given to us in the sacrament, to be the saving food of our souls — the Son of God offers daily to us in the holy sacrament the same body that he once offered in sacrifice to his Father, that it may be our spiritual food. If any one ask me concerning the manner, I will not be ashamed to confess that it is a secret too high for my reason to comprehend, or my tongue to express." A reformer of the English church would have said probably that the Romanist is decidedly in error, for the mystery that he maintains exceeds even the literal interpretation of the scripture language. Upon the truth of the Lutheran hypothesis he would decline to express an opinion, not denying the possibility of consubstantiation, but neither presuming to define the manner of Christ's presence in the elements; and he would rather recognize in the language of Calvin a right appreciation of the verity of our Saviour's expressions, and a just perception of the nature of a mystery.

CO'NSUL. In Politics, a public officer whose functions partake of the diplomatic and commercial characters. Such officers appear to have been first employed by the Italian republics, to protect their merchants engaged in trade in the cities of the Levant. The consuls of European states in that region, and in Africa, are at the present time officers of more importance than those established in the cities of Christendom; as they exercise, according to treaties, civil jurisdiction over the citizens of their respective states. In general, the consul is not regarded as a minister or diplomatic functionary, and is subject to the civil authorities of the place where he resides. A resident English merchant, acting here as consul of a foreign country, is not exempt from arrest on mesne process. English consuls are now under the regulations of stat. 6 G. 4., by which they are made salaried officers, and the fees which they are still allowed to take are specified. (See *M'Culloch's Com. Dic.*)

CO'NSULARS. The title given to Roman citizens who had been dignified with the office of consul, and consequently were honoured with a certain precedence in the senate.

CO'NSULS. The supreme magistrates of Rome after the expulsion of the kings. Their number was two, and the period of their office one year; but there was no re-

striction as to the number of times the same individual might be elected. The power of the consuls was nearly the same as that of the kings; *i. e.* they were the supreme executive officers, but had no legislative authority. In time of war it was highest; they then levied the armies, and led them in person against the enemy. The consuls were originally chosen only from the Patricians, but afterwards from the Plebeians also. The age required by law was 43 years; but besides this it was requisite to have passed through the inferior offices of quæstor, ædile, and prætor. They were elected at the Comitia Centuriata, some months before their entrance into office, which took place at different periods of the year at different times, but finally in January, during which interval they were termed *consules designati*, or appointed consuls. Soon after their entrance into office they cast lots about the provinces to fall to the share of each, the superintendence of which was conferred on them by the senate. Under the emperors the nominal office of the consulate was preserved, but its substantial power destroyed; the elections also became merely forms, the emperor appointing whom he pleased. Then too the custom was introduced of having several sets of consuls in one year; those admitted on the first day, however, gave their name to the year, and were distinguished from the others, who were termed *suffecti* (*i. e.* substituted), by the title *ordinarii* (*i. e.* regular). Persons also were sometimes dignified merely with the title without enjoying the office, and were then styled honorary consuls. Under Justinian (A. U. 1294) the year ceased to be denominated by the name of the consul.

CONSULS, in French History, were the persons (Bonaparte, Sieyes, and Ducos) to whom, after the dissolution of the Directory in November 1799, was entrusted the provisional government of the country, and at whose suggestion it was agreed that France should be permanently subjected to consular authority. According to the constitution framed on this suggestion, Bonaparte, Cambaceres, and Lebrun, called first, second, and third consuls, were elected by the conservative senate each for ten years, and invested with different degrees of authority. But the senate having passed various decrees curtailing the powers of the second and third consuls and augmenting those of the first, by which the government was gradually assimilated to a monarchy, after the lapse of four years and a half an easy transition was made from the consular to the imperial form; the title of emperor was substituted for that of consul; and the exercise of the sovereign authority, which indeed had been only nominally shared with his colleagues, delegated exclusively to Napoleon Bonaparte.

CO'NSULTA'TION (Lat.), in ordinary Legal language, is a meeting of the counsel engaged by a party to a suit, for the purpose of deliberating on the best mode of proceeding in the case.

CONSULTATION, WRIT OF. In Law, a writ granted by the king's court, whereby a cause which had been removed into such court by prohibition out of the ecclesiastical court is returned thither again. It is so called because it issues in consequence of the judges, on consultation, having found that the suggestion on which the prohibition was granted is false or not proved. *See* PROHIBITION.

CONSU'MPTION. (Lat. consumo, *I waste away*.) This term is commonly applied to a diseased state of the lungs, attended by emaciation, debility, cough, hectic fever, and purulent expectoration. It may be produced by a variety of causes; but hereditary disposition and scrophulous habit are leading causes which predispose to its most alarming form, namely, that which arises from tubercles in the lungs. Its first symptoms are cough; at first dry, but afterwards attended by mucous expectoration, difficult breathing, lassitude, and impaired appetite. These are succeeded by more copious expectoration of viscid or purulent matter, sometimes streaked with more or less blood; greater difficulty of breathing, pain in the side, especially on coughing or taking a full inspiration; and inability to lie with equal comfort upon both sides; the emaciation becomes more perceptible; and the pulse, at first not much affected, becomes full, hard, and quick; frequent flushings and fever of a remittent character ensue, attended by chills and red sediment in the urine, but the tongue is not much altered, and the mouth is usually moist; the bowels, at first irregular, become habitually relaxed; profuse perspirations, attended by extreme debility and rapid emaciation, follow; the legs swell; and the patient sinks, generally retaining the senses, and even in hope and spirits to the last. In the early treatment of this disease the tendency to inflammatory action must be most cautiously encountered by bleeding, cupping, or blisters; the bowels gently opened by saline aperients; and the cough and irritability quieted by opium, henbane, or hemlock, and by small doses of expectorants. Tonics and acids require to be given with the utmost prudence; and after all little except palliation can be effected. The diet must from the beginning be scrupulously attended to, and should be mild and nutritive, but not stimulant; and sometimes a temporary benefit results from change of air; but where the disease is once established its effect is uncertain, and it is in many cases worse than injudicious to advise change of climate. The inhalation of vapours of chlorine and iodine, in very minute quantity, has appeared to give in some cases a little temporary relief; in others it has proved decidedly mischievous; in none permanently useful; and we must with regret assume that there has been some mistake in the supposed cures of established and constitutional consumption. In its very early periods, change of country, diet, habit, and occupation will sometimes seem to suspend its progress; it has also been checked by other diseases, and not unfrequently it lies dormant in females who breed quickly; but at a later period it again shows itself, and proceeds to its fatal end.

CO'NTACT, ANGLE OF. In Geometry, the angle made by a curve line with its tangent. Euclid has demonstrated that the angle made by the circle with its tangent is smaller than any rectilinear angle, and that no straight line can be drawn between the circle and tangent without cutting the circle. Innumerable circles may, however, be made to pass between them. Formerly the angle of contact afforded geometers a fruitful source of metaphysical controversy. See an excellent account of the writings of Wallis, Peletarius, Clavius, Vieta, and others, on this subject, in the notes to *Camerer's Euclid*, Berlin, 1824.

CONTA'GION. (Lat. contagies.) The propagation of specific diseases from person to person. *Contagious poisons* communicate the property of producing similar poisons; the *small-pox* is a characteristically contagious disease. By some writers the term has been limited to diseases requiring *actual contact* for their communication; but contagious matter appears often transmissible by the air, hence the terms *immediate* and *mediate contagion*. Where diseases are propagated through the medium of the air, they are generally called *infectious*.

CONTE'MPT. In Law, disobedience to the rules, orders, or process of a court of competent authority. Contempt in court is punishable by fine or imprisonment: for contempt out of court an attachment may be granted. Contempt of the king's prerogative, by refusing to assist him in the exercise of his lawful authority, &c., is a high misprision or misdemeanor.

CO'NTEXT. (Lat. contextus.) The general series of a discourse; when we cite a particular passage, we mean by its *context* the parts immediately preceding and following it, which determine or affect its sense.

CONTINE'NTAL SYSTEM. In Modern History, the celebrated plan of the Emperor Napoleon for excluding the merchandise of England from all parts of the Continent. It was commenced by the decree of Berlin, issued 21st Nov. 1806, which declared the British islands in a state of blockade, and made prisoners of war all Englishmen found in the territories occupied by France and her allies. The blockade thus instituted was far from complete; and in the course of events licenses were expressly granted by the government for its evasion, and became a source of revenue. Some writers have affirmed that British commerce lost by this decree and those which followed it more than 60 millions sterling in 18 months; but this is an enormous exaggeration.

CONTI'NGENT. (Lat.) In Politics, the proportion (generally of troops) furnished by one of several contracting powers in pursuance of an agreement. The Germanic diet has fixed the *contingents* of the several states forming that confederacy to its army by the stipulations of 1814.

CONTI'NUAL PROPO'RTIONALS. Quantities are said to be continual proportionals, or in continued proportion, when the first is to the second as the second to the third, as the third to the fourth, and so on.

CONTI'NUED BASS. In Music, the same as thorough bass. It receives the name from its continuation through the whole of a composition.

CONTI'NUED FRA'CTIONS. In Arithmetic, a species of fractions first proposed about the year 1670 by Lord Brounker, President of the Royal Society, and improved by Dr. Wallis; but which have acquired their greatest value by their application, in the hands of the Continental mathematicians, to the solution of numerical equations, and of problems in the indeterminate analysis. Their nature will be most easily understood from a numerical example.

Let it be required to convert the fraction $\frac{108}{149}$ into a continued fraction. The value will not be altered by dividing both terms by the same number. Assume 27, which is contained in the numerator 108, and on dividing the denominator by it there will result the compound quotient $5\frac{14}{27}$. The given fraction therefore becomes $\frac{4}{5\frac{14}{27}}$, or $\frac{4}{5+\frac{14}{27}}$. Again, dividing the fraction $\frac{14}{27}$ by the greatest measure of its numerator, namely 7, it will be changed into $\frac{2}{3\frac{6}{7}}$, or $\frac{2}{3+\frac{6}{7}}$. Wherefore the original fraction is now transformed into $\frac{4}{5+\frac{2}{3+\frac{6}{7}}}$. It is, however,

more convenient to divide by such numbers as will render the numerators all units. Thus, let the fraction be $\frac{287}{992}$. Divide both terms by 287, and there results $\frac{1}{3\frac{131}{287}}$. Dividing again the terms of the last fraction by its numerator 131, there arises $\frac{1}{2\frac{25}{131}}$. Dividing again by 25, the fraction $\frac{25}{131}$ is converted into $\frac{1}{5\frac{6}{25}}$. Lastly, $\frac{6}{25} = \frac{1}{4\frac{1}{6}}$. Collecting all the fragments, we now get

$$\frac{287}{992} = \cfrac{1}{3 + \cfrac{1}{2 + \cfrac{1}{5 + \cfrac{1}{4 + \cfrac{1}{6}}}}}.$$

It is easy to see how the continued fraction is reconstructed into its equivalent simple fraction, by following the reverse process.

By decomposing a fraction in this manner a series of derivative fractions is obtained, which constantly approach to the true expression, and exhibit the successive approximate values in the lowest terms. Taking the last example, $\frac{287}{992}$: if we stop with the first term of the expansion, we find for the approximate value $\frac{1}{3}$, which is considerably too small; if we take in two terms, we find $\cfrac{1}{3+\cfrac{1}{2}} = \frac{2}{7}$, which is a little too large. Admitting three terms, we get $\cfrac{1}{3+\cfrac{1}{2+\cfrac{1}{5}}} = \frac{11}{38}$, which is again too little, but nearer the true value than the last. In this manner we approach nearer and nearer at every successive step; and it may be remarked, that the errors are alternately in excess and defect. (See *Leslie's Philosophy of Arithmetic; Euclid's Analysis Infinitorum;* and the *Additions* to the French translation of *Euler's Algebra*.)

CONTINU'ITY, LAW OF. A principle of considerable use in investigating the laws of motion, and of change in general, and which may be thus enunciated: — *Nothing passes from one state to another without passing through all the intermediate states.* Leibnitz claims the merit of having first made known this law; but in so far as motion at least is concerned, it is distinctly laid down by Galileo, and ascribed by him to Plato. But though a perception of its truth seems to have been felt long before, Leibnitz was certainly the first who applied the principle to test the consistency of theories, or supposed laws of nature. The argument on which he attempted to establish it *à priori* is, that if any change were to happen without the intervention of time, the thing changed must be in two different conditions at one and the same instant, which is obviously impossible. A remarkable application of the law of continuity was made by John Bernoulli in an Essay on the Laws and Communication of Motion, which gained the prize of the Academy of Sciences of Paris in 1724, to prove that perfectly hard bodies cannot exist; because, in the collision of such bodies, a finite change of motion must take place in an instant, an event which, by the law now explained, is impossible. This conclusion was objected to by D'Alembert and Maclaurin, who on account of it were disposed to reject the law of continuity altogether; but the difficulty is got over by supposing (which on various grounds is extremely probable) that there is no real contact, and that bodies begin to act on each other when their surfaces, or what seem to be their surfaces, are yet at a distance.

CONTO'RNIA'TI. In Numismatics, medals supposed to have been struck about the period of Constantine the Great and his immediate successors; they are of bronze, with a flat impression, and marked with peculiar furrows. (Ital. contorni, whence their name.) They bear the figures of famous emperors or celebrated men. Their object is uncertain; but they have been supposed to be tickets of admission to the public games of the circus in Rome and Constantinople.

CONTOUR. (It. contorno.) In the Fine Arts, the external lines which bound and terminate a figure. The beauty of contour consists in those lines being flowing, lightly drawn, and sinuous. They must be carefully and scientifically drawn, which cannot be effected without a thorough knowledge of anatomy.

CO'NTRABA'ND. (Ital. contra, *against;* bando, *an edict* or *proclamation.*) In Commercial language, goods exported from or imported into a country against its laws. *Contraband of war*, such articles as a belligerent has, by the law of nations, the right of preventing a neutral from furnishing to his enemy. Articles contraband of war are, in general, arms and munitions of war, and those out of which munitions of war are made; all these are liable to be seized: but very arbitrary interpretations have been affixed to the term by powerful states, when able to enforce them by arms. Thus provisions are held contraband of war when it is the object to reduce the enemy to famine. But with respect to these and other articles not in their nature contraband, it seems to be the practice that the belligerent should purchase them from the neutral for a reasonable equivalent, instead of confiscating.

CONTRABA'SSO. (It.) The largest of the violin species of string and bowed instruments, whereof it forms the lowest bass, usually called the double bass.

CO'NTRACT. In Civil Law, the term usually applied to such agreements, whether express or implied, as create, or are intended to create, a legal right, and corresponding liability; such right not attaching to the possession of the subject matter of the contract, except in equity, and that indirectly, but subsisting both in equity and law against the contracting party.

The conditions essential to the legal validity of a contract relate either to the competency of the parties, the sufficiency of the consideration or inducement, the nature of the thing contracted for, the fairness of the transaction, or, lastly, to the form of the agreement.

And, first, as to the competency of the parties. The party to be sued must have been at the time of the contract of sound mind, and, unless it was for the supply of necessaries, of full age; and if a woman, she must have been unmarried, subject as to the latter condition to some exceptions established either by local custom or by the doctrines of equity.

Secondly, as to the sufficiency of the consideration on the part of the person suing, — it must have been either future marriage since performed, or money, or something capable of being estimated in money; or some act, whether of performance or abstinence, whereby some undoubted advantage, though not capable of being exactly valued, accrues to the party sued.

Thirdly, the act contracted for must be neither contrary to written law, nor to public policy; and it must be beneficial to the party seeking either performance or compensation, or to some one on whose behalf he gave the consideration.

Fourthly, there must have been neither fraud (either by concealment or misstatement) nor compulsion on the part of the plaintiff in obtaining the agreement; and fraudulent acts subsequent to the agreement having reference to it are also sufficient to deprive the guilty party of all right under it. Some circumstances are in equity considered either as conclusive evidence of fraud, or as substantive acts of coercion, which are not strictly of such a nature, and are not so deemed at law.

Lastly, as to the form of the agreement. Where it relates to an interest in land of three years' duration or more, or to goods of the value of 10*l*. or upwards, unless there be earnest or delivery, or where it is an agreement as surety, or where it is upon marriage as a consideration, it must be in writing; though the want of a written instrument may be supplied in equity by partial performance, that is, by acts evidently done in pursuance of the alleged contract.

Contracts are sometimes implied either in the whole from the acts of the parties, as from the ordering of goods a contract to pay for them; or in part, and as incidental to the principal agreement, as, in the case of a lease, a contract by the tenant to use fairly and take due care of the thing leased. And at law some obligations not arising in any manner from contract are, as regards the mode of enforcing them, placed on the same footing as those which do arise from contract; the remedy, and not the right, being assimilated by statute.

Such are the general requisites to the validity of agreements; but at law the extent of the right and liability arising under them varies according to their form; agreements being there divided into those under seal, which are called agreements by specialty, and those not under seal, which are called simple contract or parol agreements, including not only such as are merely verbal, but such as are written and unsealed. The first sort alone are binding upon the land, and that only when the heir is named; and they possess this farther advantage over agreements by simple contract, that being executed as the *deed* of the contracting party, a sufficient consideration will always be implied in their favour, unless an insufficient one be actually stated on the face of them. Again, agreements both by specialty and simple contract are either to pay a sum certain actually stated in the agreement, or a sum uncertain to depend upon the value of the thing received; or they are agreements to perform certain acts. In the first case, the remedy is by action of debt either on bond or covenant, or upon simple contract, as the case may be. In either of the latter cases the remedy is by action for breach of covenant where the agreement is under seal, or by action of assumpsit where it is by simple contract; the relief given in each of the two last-mentioned sorts of action being compensation in damages for the injury accrued from non-performance of the agreement. *See* ACTION.

The remedy in equity, where there is any, is in all cases alike. — specific performance of the act agreed to be done; and such relief will be given to the same extent and against the same parties, whether the contracting party himself or his real or personal representatives,

without any distinction between agreements under seal and those which are not so.

But though courts of equity have jurisdiction in all cases of agreements, at least in all such as do not constitute an actual debt at law, yet the exercise of that jurisdiction is, subject to certain rules, a matter of discretion; for the reason that the denial of the equitable relief will not leave the party without some remedy, namely, that of damages at law: and on this account specific performance can only be obtained in equity in those cases where pecuniary damages would not afford to the disappointed party an adequate compensation. Thus such relief will not be granted in any of those cases where the inducement to the bargain or agreement was merely the expectation of profit, as it is in agreements for the sale or purchase of personal chattels; and other circumstances also are a bar to equitable relief, which are no defence to an action at law, as, for instance, the want of mutual liability, apparent laches, and indifference in following up the agreement; or particular consequences of collateral hardships arising to one party from actual performance; or the impropriety in equity of the agreement, as where performance would be a breach of trust. And on the other hand, though the equitable jurisdiction is founded upon a supposed legal right, there are cases in which the right having been lost at law, as by default in literal compliance with the terms of the agreement, will yet be enforced in equity.

Contract, Original or Social. In Politics, that which is supposed to exist ab initio, according to some theories of government, between the sovereign power and the subject. So prevalent was this doctrine at the period of the revolution of 1688, that the Convention Parliament pronounced James II. to have broken the "original contract between the king and the people." The original contract, with the reciprocity of rights and duties which it engenders, is clearly a supposition having no historical foundation in the annals of any people; but it is, nevertheless, the only hypothesis in which men can consistently proceed in framing a theory of government which shall satisfy at once the moral and economical wants of society.

CONTRADI'CTORY PROPOSITIONS. In Logic, are those which having the same terms differ in quantity and in quality. *Contrary Propositions* are two universals with the same terms, the one negative and the other affirmative. *See* Proposition.

CONTRA'LTO. (It.) In Music, the part immediately below the treble; called also the counter tenor.

CO'NTRAST. (Fr. contraste.) In the Fine Arts, an opposition of lines or colours to each other, so contrived that the one gives greater effect to the other. By means of contrast energy and expression are given to a subject, even when employed on inanimate forms. All art is indeed a system of contrast: lights should contrast with shadows, figures with figures, members with members, and groups with groups. It is this which gives life, soul, and motion to a composition.

CO'NTRATENO'RE. In Music, the same as *Contralto*, which see.

CO'NTRAVALLA'TION. (Lat. vallum, *trench*.) In Fortification, a trench guarded by a parapet, formed by the besiegers between their camp and the place besieged, to secure themselves and check the sallies of the garrison. The line of *contravallation* is thus, as the name implies, a sort of *counter* fortification.

CONTRO'L, BOARD OF, or BOARD OF COMMISSIONERS FOR THE AFFAIRS OF INDIA, is constituted under the authority of Mr. Pitt's celebrated Act, passed in 1783. It consists of such members of the privy council as his Majesty is pleased to appoint, of whom the two principal secretaries of state and chancellor of the exchequer always form three. The president is usually a cabinet minister. The controlling functions of the board consist in revising all despatches prepared by the court of directors and addressed to the governments in India. It also has the power of requiring the court to prepare despatches on a given subject, and revising and altering them. The board is divided into six departments,—accounts, revenue, judicial, military, secret political, and foreign and public. The names of the first four indicate their duties: the third has three subdivisions,—the secret departments, respecting confidential communications addressed (as the act prescribes) by the local governments to the secret committee of the court of directors, and vice versâ; the political, comprising general correspondence respecting native chiefs and states; the foreign, respecting foreign Europeans and Americans resorting to India. The public department takes charge of commercial, ecclesiastical, and other miscellaneous affairs. The salary of the president of the board is 3500*l*., that of a paid commissioner 1200*l*., of the secretary 1500*l*.

CONTRO'LLER. (Fr. controleur.) An officer appointed to control or oversee the accounts of other officers, and to certify whether the matters confided to his care have been controlled or examined. In England, there are several public functionaries of this title, as the controller of the mint, customs, stationery, &c.

CO'NTUMACY. (Fr. contumace, *stubborn*) In Scotch Ecclesiastical Law, a wilful disobedience to any lawful summons or judicial order. It is punished by imprisonment.

CO'NUS. (Gr. κωνος, *a cone*.) A term in Botany, denoting that form of inflorescence called a strobilus or cone, which is a spike, the carpels of which are scale-like, spread open, and bear naked seeds. Sometimes the scales are thin, with little cohesion; but they often are woody, and cohere into a single tuberculated mass.

Conus. The name of a Linnæan genus of *Vermes Testacea*, characterized by the conical form of the shell, the base of which is formed by the spire, which is accordingly flat, or very slightly projecting; the aperture is narrow and rectilinear, or nearly so, without any enlargement or plication. The genus is retained without subdivision, and forms part of the *Buccinoid* family of the Pectinibranchiate order of Gastropods in the system of Cuvier.

CO'NVENT. (Lat. conventus, from convenio, *I come together*.) A religious house, inhabited by a society of monks or nuns. *See* Monachism.

CONVE'NTICLE. (Lat., diminutive of conventus.) An assembly for the purpose of divine worship; first used in a contemptuous sense for the meetings of the followers of Wicliffe (stat. 2 H. 4. c. 15.), and since applied to the places of meeting of petty sects and of Dissenters in general in the Conventicle Act, 16 Car. 2., repealed by 52 G. 3. c. 155. Originally the word had no such peculiar application, but was used by the fathers and ancient writers for a church.

CONVE'NTION. In Political language, this name has been applied to assemblies of national representatives meeting on extraordinary occasions without being convoked by the legal authority. Two parliaments have been so called in English history. The first, that which met in April, 1660, and restored Charles II. to the throne—the Lords assembling by their own authority; and the Commons, by virtue of writs issued in the name of the keepers of the liberties of England, by the authority of parliament. The second, that which met in 1688, each house by its own authority, and on the summons of the Prince of Orange; which declared King James II. to have abdicated the crown, and transferred it to William and Mary. In French History, the name Convention is applied to that assembly which met after the legislative assembly had pronounced the suspension of the royal functions, in September, 1792, and proclaimed the republic at its first sitting. This body dissolved itself on the establishment of the Directory, in October, 1796. The Scottish assembly which met on the flight of James II. was entitled the Convention of Estates. In the United States, meetings of the people of separate states, by specially chosen representatives, to review and amend the state constitutions, have been termed Conventions.

Conve'ntion, Military. A treaty between military commanders concerning terms for a temporary cessation of hostilities; generally between a victor and a defeated general, for the evacuation of a district or position by the latter. Such, at least, were the two most celebrated conventions of modern times: that of Closter-Seven (1757), between the Dukes of Cumberland and Richelieu; that of Cintra (1808), between Junot and the English generals.

CONVE'RGENT-NERVED. A term used in describing the venation of leaves, to denote cases where the ribs form a curve and meet at the point, as in *Plantago lanceolata*.

CONVE'RGING SERIES. In Analysis, are series of which every succeeding term is smaller than the preceding, and which, consequently, tend to a certain limit. It is only converging series which admit of summation.

CO'NVERSE. In Geometry, a proposition is said to be the converse of another when the conclusion of the first being used as the supposition in the second, the conclusion of the second agrees with the supposition of the first. Thus, the fifth proposition of the first book of *Euclid* affirms that if the two sides of a triangle be equal, the angles at the base are equal; and the sixth affirms that if the angles at the base be equal, the two sides are equal. The sixth is therefore the *converse* of the fifth.

CONVE'RSION. In Logic, a proposition is said to be *converted* when the terms are so transposed that the subject is made the predicate, and vice versâ. All logical conversion is illative; *i. e.* the truth of the converse follows from that of the original. Conversion is either "simple" or "per accidens." Universal negatives (denoted by the sign E) and particular affirmatives (I) can be converted simply, retaining both quantity and quality: thus, "No virtuous man is a rebel;" "No rebel is a virtuous man." Conversion per accidens changes either quantity or quality. Universal affirmatives (A) are converted by changing the quantity; as. "All oaks are trees;" "Some trees are oaks." Particular negatives (O) by changing the quality, considering the negative as attached to the predicate instead of the copula: the proposition is

thus changed into I,—"Some poets are not learned;" "Some not learned (unlearned) men are poets." *See* PROPOSITION.

CO'NVERT. (Lat.) A person who changes his religion. Individuals, of what faith soever, who abandon their own creed and embrace Christianity are called *converts*, in contradistinction to *apostates*, applied generally to *Christians* who adopt another religion. History, both sacred and profane, has transmitted to us many instances of sudden conversion, in which the hand of a miraculous providence may clearly be traced. Among the most remarkable may be mentioned the conversion of 3000 Jews on the day of the Feast of Tabernacles, and that of Paul the apostle, the emperor Constantine, and Clovis, king of France.

CONVEY'ANCE. (From *convey*.) In Law, a deed which passes land from one to another. (*See* REAL PROPERTY, LAW OF.) *A conveyancer* is a lawyer, whose business consists in advising and preparing such deeds. It is not necessary to be called to the bar to practise as a conveyancer; but most conveyancers take that step soon after beginning their business, and frequently combine it with that of equity draftsmen.

CONVI'CTION. At Common Law, is the finding of one guilty of an offence by the verdict of a jury; and may take place where one is outlawed, or appears and confesses, or is found guilty on the inquest. (*See* JURY, VERDICT.) By various statutes summary proceedings, without the intervention of a jury, are authorized for the trial and conviction of minor offenders. Such are those before commissioners of excise, &c. for breaches of the revenue laws, and before justices of the peace for various disorderly offences. The party charged must be summoned to attend; and a conviction by a magistrate must be in writing, and should state the whole of the evidence for and against the defendant.

CONVOCA'TION. (Lat. convoco, *I call together*.) In English Ecclesiastical Law, the council of the church, derived, first, from the custom of the bishops assembling their diocesan clergy for the sake of considering spiritual matters; and, secondly, of the archbishops holding convocations of the clergy of a whole province. Convocations were first assembled in England under the king's authority by Edward I., who summoned them by their provinces, for the sake of obtaining subsidies from the clerical body. They met in each province in two houses — one of the suffragan bishops; the other of deans, archdeacons, and representatives of the inferior clergy. The taxation of their own body was withdrawn from convocation in 1664; and, on the other hand, the privilege of voting for knights of the shire was then conceded to ecclesiastics. As the power of enacting canons had been already virtually abolished by statutes of Henry VIII., Elizabeth, and Charles II., there now remained no business for convocation to transact; and it was only in the reigns of William III. and Anne, when attempts were made by the high church party to impart fresh activity to it as an ecclesiastical tribunal, that its meetings were attended with any historical importance. Since that period it has become customary to prorogue convocation every year immediately upon its assembling. The rights and history of the convocation are treated of at length in several writings of the learned Bishop Gibson, especially his *Synodus Anglicana*, Lond. 1702.

CONVOCA'TION, HOUSE OF, in the University of Oxford, is the assembly which enacts, amends, &c. laws and statutes; elects burgesses, many professors, and other officers, &c. It is composed of all members of the university who have at any time been Regents (*see* REGENTS), and who, if independent members, have retained their names on the books of their respective colleges. The power of convocation at Oxford to make statutes is limited: in the first place, the royal statutes cannot be explained or amended without royal license; and, in the next place, with respect to all other laws and statutes, no proposition can be entertained in convocation unless it has been first submitted to the hebdomadal meeting of heads of houses, by whom it must be in the first instance sanctioned or rejected.

CONVO'LVULA'CEÆ. (Convolvulus, one of the genera.) A natural order of herbaceous or shrubby Exogens, twining and producing a milky juice when wounded. They are very abundant in the tropics, and possess purgative qualities in their roots, depending upon a peculiar resin, of which scammony and jalap, yielded by the *Convolvulus Scammonia* and *Ipomœa purga*, may be taken as examples. Many of these plants are objects of striking beauty; some, which unfold their pure, white, magnificent flowers at night only, are called in tropical countries *Belle de Nuit*; others expand only beneath a warm and brilliant sunshine. The *Lignum Rhodium* of the old pharmacologists is produced by an upright bushy species, called *Breweria scoparia*.

CO'NVOY. (Fr. convoyer, *to conduct*.) In Navigation, the term applied to designate a ship or ships of war, appointed by government, or by the commander in chief on a particular station, to escort or protect the merchant ships proceeding to certain ports. Convoys are mostly appointed during war; but they are sometimes also appointed during peace, for the security of ships navigating seas infested with pirates. For an account of the various regulations and conditions relative to convoys, see *M'Culloch's Com. Dict.*

CONVOY, in the Military service, signifies a detachment of troops appointed to guard supplies of provisions, ammunition, or money, in their progress to a distant part of any country, or to an army in the field, against an attack which might be made upon them either by the peasantry or by parties of the enemy.

CONVU'LSION. (Lat. convello, *I pull together*.) A writhing and agitation of the limbs, and involuntary action of the muscles in general. The fits vary much in extent and violence, sometimes attacking the whole body, and at others confined to particular parts; in the former case the mind is affected, but it often remains in the latter undisturbed: they also vary in duration, lasting from a few minutes to some hours. They are sometimes preceded with dizziness, double or disturbed vision, and coldness, and are followed by great languor; but at others they come and go without much disturbance. Teething, worms, and overloaded bowels are common causes of convulsive attacks in children; and these are relieved by freely and timely lancing the gums, and by the administration of proper purges. In *puerperal convulsions* bleeding and opiates are the usual remedies; and in cases where convulsive attacks arise from violent affections of the mind, the exciting causes must be studiously avoided. Warm baths, bleeding, and nervine stimulants are the usual medical aids; and where there is difficulty of swallowing, a glyster, composed of half a pint of gruel with a drachm of tincture of opium and two drachms of tincture of assafœtida, has, in adults, proved eminently useful. Cold affusions often do harm. The after-treatment consists in the judicious use of tonics and nervous stimulants, and in avoiding all obvious exciting causes.

COO'LER. An apparatus used by brewers and distillers for cooling worts. The coolers generally consist of very shallow vessels exposing great surface, and placed in the high and airy parts of the brewery: the cooling is sometimes assisted by fans, which agitate the air over their surfaces. Worts are also occasionally cooled by causing them to traverse metal pipes, which are surrounded by a counter-current of cold water.

CO-O'RDINATES. (Lat. con, *together*, and ordino, *I arrange*.) In Analytical Geometry, the system of lines to which points under consideration are referred, and by means of which their position is determined. The position of a point on a plane is absolutely determined if we know its distances, measured in a given direction, from two straight lines given by position in the same plane. In like manner, the position of a point in space is determined by its distances from three straight lines given by position, provided any one of them be not in the same plane with the other two. The use of co-ordinates was introduced into geometry by Descartes, for the purpose of facilitating the investigation of the properties of curve lines. For the sake of convenience, they are generally chosen at right angles to each other, and are then called rectangular co-ordinates. In plane geometry, one of them is the *absciss*, and the other the *ordinate*. The geometry of three dimensions requires one absciss and two ordinates; the first horizontal, and the second vertical. The point from which they all proceed is the *origin of the co-ordinates*.

COPAI'BA or COPIVI BALSAM. An exudation from the *Copaifera officinalis*, a South American tree; it is a liquid resin, and yields by distillation a considerable quantity of a pungent volatile oil. A small teaspoonful taken twice a day in a glass of water proves diuretic, and is of use in the cure of gleet and the latter stages of *gonorrhœa*. A larger dose is aperient, and has been of service in the treatment of *hæmorrhoids*.

CO'PAL. (An American name applied to clear gums?) This substance is often improperly called *gum copal*. It is a peculiar resin, very difficultly soluble in alcohol; hard, brittle, and inodorous: its specific gravity varies from 1·04 to 1·13. It is the produce of the *Rhus copallinum* and of the *Elæocarpus copaliferus* of the East Indies: a third kind of copal is also brought from the Coast of Guinea. It is used in varnishes.

COPA'RCENARY. (Lat. con, and particeps.) In Law, an estate is said to be held in coparcenary, and the tenants termed coparceners, where it descends from an ancestor to two or more persons. Sisters are coparceners at common law; tenants in gavelkin by custom. No right of survivorship exists between coparceners. They may agree, or any one may force the rest to make partition.

CO'PING. (Sax. cop, *the head*.) In Architecture, the upper covering or top course of a wall, usually of stone, and wider than the wall itself, in order to let the rain water fall clear from the wall.

CO'PPER. (*Cuprum*, a corruption of *Cyprium*, from the island of Cyprus, whence it was formerly brought.)

This metal was known at a very remote period; and in the early ages of the world, before iron was in use, copper was the chief ingredient in domestic utensils and instruments of war. It is an abundant metal, and is found native, and in many ores; of these the most important are the varieties of *pyrites*, which are sulphurets of copper and iron. The richest mines are those of Cornwall. It occurs in veins, traversing the primary rocks of that county; it is chiefly transported to Swansea to be smelted, in consequence of the deficiency of coal in Cornwall. The ores are repeatedly roasted and fused to drive off the sulphur, and the oxide of copper is ultimately reduced by the joint agency of heat and carbon. Copper is distinguished by its colour. Its specific gravity is 8·6. It is ductile and malleable, and requires a temperature equal to about 2000° of Fahrenheit's scale for its fusion; that is, nearly a white heat. Exposed to air and moisture, copper gradually becomes covered by a green rust; heated red hot it absorbs oxygen, and is superficially converted into a black oxide, which is the basis of the principal salts of copper: it consists of 32 copper and 8 oxygen. It forms blue or green salts with the acids; of these the *sulphate of copper*, or blue vitriol, is a good example. The salts of copper are poisonous; and in consequence of the use of copper vessels for culinary purposes, food is sometimes contaminated by them. It is detected when in very minute quantities by the bright blue colour produced by the addition of liquid ammonia, and by a brown precipitate with ferrocyanate of potash. A clean plate of iron dipped into a solution containing copper becomes covered with the latter metal in a metallic state.

COPPERAS. Green vitriol, or sulphate of iron.

CO'PPERPLATE. In Engraving, a plate of copper highly polished on which an engraving is made.

CO'PPICE. Woods which are cut down at stated periods to be manufactured into poles, rods, stakes, faggots for fuel, bark for the tanner, or charcoal. When wood of this kind has no standard trees, it is called simply a coppice, or copse wood; but when it has standard trees interspersed through it, it is called a wood. When coppices are cut down for hoops, rods, and small stakes for manufacturing into crates, hoops, wicker hurdles, &c., the period at which they are cut varies from six to ten years, according to the soil. When they are cut down for poles for hops and similar purposes, the periodical cuttings are commonly between twelve and fourteen years apart; and when they are cut down chiefly for the sake of the bark, they are seldom cut oftener than from fourteen to twenty-one years. A country abounding in coppice wood generally abounds also in singing birds, which are comparatively rare in countries where all the woods are of the pine and fir tribe.

COPRO'PHAGANS, *Coprophaga*. (Gr. κοπρος, *dung*, and φαγω, *I eat*.) A section of Lamellicorn beetles which live in and upon the dung of animals.

CO'PULA. (Lat. *a bond or tie*.) In Logic, that part of the proposition which affirms or denies the predicate of the subject. The only true logical copula is the present tense of the verb *to be*, with or without the negative sign, "is" or "is not."

CO'PY. (Fr. copie.) In the Fine Arts, a transcript from an original work of art. When an artist copies his own work, it is called a *duplicate* or *double*.

COPY. In Printing, is the subject matter to be printed, whether it be an original work in manuscript or a reprint: in the first case it is termed manuscript copy, or written copy; in the second printed copy.

CO'PYHOLD. In Law, is a species of *customary estate*, said to be held by copy of court roll; *i.e.* where the tenant's title is evidenced by a copy of the rolls of a manor made by the steward of a lord's court. Customary estates are those which exist in real property subject to the custom of manors; and their peculiar characteristic is, that all alienations of them must be transacted, in part at least, in the lord's court, the ordinary mode of alienations being by surrender to the lord and admittance of the new tenant. The peculiar tenure called copyhold is derived from the tenure in *villain socage*, as it was termed, held formerly under a manor. This was in its origin a mere permissive tenure by serfs attached to the soil; and copyhold estates are still expressed in legal phraseology to be held "at the will of the lord by the custom of the manor." With respect to the incidents of dower, and other characteristics, they are frequently governed by the custom of the manor; but where this is not the case, they are under the same rules which govern the transmission and alienation of freehold property. By the Reform Act, copyholders for life, or a greater estate to the amount of 10*l*. per annum, are admitted to the exercise of the electoral franchise in counties. The best treatises on the law of copyholds are those of *Watkins* and *Scriven*.

CO'PYRIGHT. In Law, the right of property in a literary composition vested in the author. By 54 G. 3. c. 156. s. 4. the term of copyright in an author and his assignee extends to twenty-eight years absolutely, and for the life of the author if he survive that period. Neglect to enter a work at Stationers' Hall does not affect copyright. Every assignment of copyright must be in writing. The author or assignee of a pirated work has his remedy by action; or chancery will grant an injunction to restrain the sale of pirated copies, and produce an account of such copies printed and sold. The act above mentioned required that eleven copies of every work should be delivered at the expense of authors and publishers, on demand in writing, for the use of a few favoured public and private libraries in the United Kingdom; but by the 6 & 7 Will. 4. cap. 110. the number was reduced to five. In France, copyrights continue for 20 years after the death of the author. In most of the German states, they are perpetual; and to prevent spurious copies being introduced from other states, a late resolution of the Diet has declared that a copyright secured in one state is good in all. Both in England and on the Continent, various other compositions, such as engravings, etchings, prints, maps, charts, and sculpture of all kinds, receive from statute a protection analogous to that of literature.

CO'RACLE. A boat made of wicker-work covered with leather, used chiefly by the ancient Egyptians.

CO'RACOID. (Gr. κοραξ, *a crow*, and ειδος, *form*.) A name first applied to a small process of the blade-bone of apes and man, on account of its resemblance to the beak of a crow; and now extended to a large flattened bone passing from the shoulder-joint to the sternum in birds, reptiles, and monotremes, and of which the process above mentioned is the rudimental representative.

CORALLI'NA. A name applied by Linnæus to a genus or group of marine organized bodies of arborescent habit, with jointed stems, supported on a kind of root, divided into branches, which are likewise jointed. Neither pores nor polypes are distinguishable on the surface of these beings; their chief purpose in the economy of nature is to prepare during life, and precipitate by their decay, fine particles of carbonate of lime or chalk: they thus lend their aid to the Lithophytous corals in covering submerged land with the elements of a fertile soil, which the expansive subterranean forces may afterwards convert into dry land.

CORALLI'NES. The name commonly applied to the tubular or nudibrachiate order of Polyps which have an external jointed calcareous or horny covering: the true nature of these plant-like animals was discovered by our countryman Ellis. *See* TUBULIFERA.

CO'RBEILS. In Fortification, little baskets filled with earth, about a foot and a half high, and from eight inches to a foot in diameter, which are set on a parapet or elsewhere to afford cover from the fire of an enemy.

CO'RBEL. (From the Fr. corbeille, *a basket*.) In Architecture, a projecting bracket, often sculptured like a modillion, sometimes in the form of a basket, for the purpose of supporting a superincumbent object, also for receiving the springing of an arch. A *corbel table* is a projecting battlement, parapet, or cornice, resting on corbels.

CO'RCULUM. (Lat. cor, *the heart*.) An old name for what botanists now call the embryo of a plant. It was not, however, applied with much precision; for the plumula and radicle alone of such seeds as the bean and almond were called the corculum, while the term should have included the cotyledons also.

CO'RDATE. (Lat. cor, *the heart; literally heart-shaped*.) A term used in describing the general form of organs, to denote any thing having two round lobes at its base, the whole resembling the heart in a pack of cards; as the leaf of *Alnus cordifolia*.

COR'DIA'CEÆ. (Cordia, one of the genera.) A natural order of arborescent Exogens, inhabiting the tropics of both hemispheres. They are nearly allied to *Convolvulaceæ*, from which they are separated by their inverted embryo and drupaceous fruit. They were formerly associated with *Boraginaceæ*; but their plaited cotyledons and dichotomous style caused them to be removed. The flesh of the fruit is succulent, as seen in the Sebesten plums, the produce of the *Cordia myxa* and *Sebestena*; but otherwise they are of no value. It has been asserted that the wood from which the mummy cases of the Egyptians were made was that of *Cordia myxa*; but there is no doubt that it was really produced by *Ficus sycomorus*.

CO'RDON. In Fortification, a row of stones jutting out between the rampart and base of the parapet. A line of troops drawn round a town or tract of country, so as to prevent ingress or egress, is also called a cordon.

CO'RIA'RIA'CEÆ. (Coriaria, one of the genera.) A natural order of shrubby Exogens, inhabiting Chile, Peru, the south of Europe, and a few other places. Placed by De Candolle directly after *Ochnaceæ*; an order with which they no doubt agree in some respects, but they differ from them very essentially in being apocarpous. Some botanists consider them apetalous, and allied to *Phytolaccaceæ*; the question of their affinity is still unsettled. Their sensible properties are of a poisonous nature.

CORIA'NDER. The seed of the *Coriandrum sativum*. (Gr. κορις, *a bug*, the odour of the fresh plant resembling

that of the bug.) It is a native of Europe, cultivated on account of its seeds, which are occasionally used in medicine; they have a peculiar perfumed flavour, with some bitterness, and form one of the ingredients of *curry powder.*

CORI'NTHIAN ORDER. In Architecture, one of the five orders of architecture. The capital (*see* ARCHITECTURE) is a vase elegantly covered with an abacus, and surrounded by two tiers of leaves, one above the other; from among which stalks spring out, terminating at their summits in small volutes at the external angles and centres of the abacus. The capitals of the Tuscan, Doric, and Ionic orders appear added to the tops of the shafts; but the Corinthian capital seems to grow out of the column, varying in height from a diameter and one sixth of the lower part of the shaft to one diameter only; such last being the height of the capitals of the temple at Tivoli. The entablature of this order is variously decorated. The architrave is usually profiled, with three fasciæ of unequal height, though in some specimens there are only two. The frieze is often sculptured with foliage, and the cornice decorated both with modillions and dentils; the former having a sort of baluster front with a leaf under them; and the latter, which are cut into the body of the band, being occasionally omitted, as are sometimes even the modillions. The principal remaining ancient examples of the order at Rome are in the Temple of Mars Ultor, Portico of Severus, the Forum of Nerva, Temple of Vesta, Basilica of Antoninus, the Pantheon, &c. &c.

CORK. (Corrupted from Lat. cortex; Germ. kork.) The bark of the *Quercus suber*, a species of oak growing in the southern provinces of Spain, France, and Italy. When rasped cork is digested in water and alcohol, it leaves from 70 to 80 *per cent.* of insoluble matter, which has been called *suberine*, and which, by the continued action of nitric acid, is converted into *suberic acid.*

CO'RMUS. (Gr. *κορμός, a stem.*) In Botany, a short roundish rhizoma.

CORN. The seeds of certain grasses which have been immemorially used as food, for man or animals, are called corn; and those which are used exclusively or principally by man are called bread corns. The term corn is also sometimes applied to the seeds of other plants which may be ground into meal and used as food, such as the seeds of the buckwheat, the quinoa, and of certain leguminous plants, which, however, are more properly denominated pulse. The principal bread corns of temperate climates are wheat, rye, oats, and barley; those of warm climates are maize, rice, and millet; and those of cold climates oats and barley.

It may be worthy of remark, that all bread corns are annual plants, and from that circumstance far better adapted for universal cultivation than if they had been perennials, or even biennials. An annual plant may indeed be said to belong to no country in particular, because it completes its existence during the summer months; and in every part of the world there is a summer. Hence, we find the same corns ripening their seeds within the frigid and the torrid zone; and though the quality of barley and wheat grown in Lapland be far inferior to that grown in the south of Spain, or on the plains of India, yet it is still such as may be made into wholesome bread and invigorating fermented liquor. Had the bread corns been perennials, they must necessarily have lived through the winter in every country in which they were grown, as well as through the summer; and such of them as might have been adapted to the winters of cold climates, when taken to warm climates would have been so far weakened by being kept in a growing state throughout the year as in a few years to have ceased to exist; while the perennials of warm climates, such as the south of Spain and Italy, could not have lived through a single winter in Russia or Lapland. For the same reason, that is, because they are annuals, and require little more than to be sown and reaped, the bread corns are in an especial manner the domestic plants of man in an early stage of civilization. A people like the wandering Arabs, who live in tents, and change their encampments annually or oftener, may conveniently reap their crop, raise their tents, and carry their seed corn about with them, till they find a suitable spot where they can pitch their tents and take their next crop. This, however, could not be done by a people who, in addition to corn and pulse, depended for the food of themselves and cattle on the production of roots, such as the turnip and the potatoe; and these accordingly are plants characteristic of a settled people, in a higher degree of civilization and a greatly advanced state of agriculture. The capacity of any country for growing corn may be said to be according to the flatness of its surface, provided it be neither too hot nor too cold, too wet nor too dry. The perennial grasses and trees also grow better in plains than any where else; but they will thrive on the steep declivities of hills, which, if subjected to tillage in order to grow corn, would have the surface soil washed away by rains and thawing snows.

Value of the Produce of Corn. — In agricultural countries, not in a very high state of civilization, the culture of corn is the principal employment of the great bulk of the community; and in all considerable countries, how far soever they may be advanced in arts and refinement, its culture is always by far the most extensive as well as the most important branch of national industry. No great country, perhaps, ever existed, the population of which was so extensively engaged in manufactures and commerce as that of Great Britain. Still, however, we employ about a *third part* of our inhabitants in agriculture; and of these, fully three fourths are directly or indirectly engaged in the raising of corn. Unfortunately, there are no accounts, on which it would be safe wholly to rely, of the ordinary produce of corn either in this or any other great country. But, without pretending to peculiar accuracy, we are inclined to think that the present (1842) average growth of all sorts of corn in the United Kingdom may be safely estimated at about 64,000,000 quarters, of which about 55,000,000 may be consumed by man, and the lower animals. (See *post.*) Now supposing this estimate to be nearly accurate, and taking the average price of the different descriptions of corn at 35*s.* a quarter, the total value of the corn annually produced will amount to the sum of 112,000,000*l.* sterling, or to nearly or quite four times the total annual value of the cotton manufacture! This is sufficient to evince the paramount importance of agriculture as a source of wealth as well as a means of subsistence.

Corn Laws. — This superior importance of corn as an article of culture, and the dependence so generally placed upon it as an article of food, are the causes why the trade in it has been so very generally subjected to regulation. It is long even before the most enlightened portion of an instructed community become satisfied of the advantage of permitting the supply of corn or any indispensable article to be adjusted, like that of other less important things, by the unfettered competition of private individuals. It seems, at first sight, reasonable to suppose that the most likely way to secure plenty at home is to impose restrictions on exportation. But in truth and reality, this is very far from being the case. How fertile soever, no country that imposes restrictions on exportation need hope to escape perpetually-recurring scarcities; for wherever free exportation is prevented, the excess of supply that occurs in plentiful years being thrown wholly upon the home market depresses prices to such an extent as to be ruinous to the farmer: and thus, by injuring agriculture and lessening the quantity of land in corn, never fails to occasion a scarcity on the occurrence of a deficient harvest. In Great Britain, however, the policy has long been to give every facility to exportation, and even to lay restrictions on importation. This has arisen from our legislature being principally composed of individuals dependent on and connected with the land; and whose interest consequently has led them to endeavour to secure as high a price as possible for its produce. But it is needless to add that this policy is, if possible, even more objectionable than the other. Instead of being publicly advantageous, high prices are, in every instance, distinctly and completely the reverse. The less the sacrifice of money or of labour for which corn or any other article can be procured so much the better. But to make sure that the price of corn, or of any thing else, will be fixed at the lowest limit at which the required supply can be obtained, all that is necessary is to abolish all restrictions, whether on exportation or importation. Freedom is the parent of abundance, cheapness, and equality of price; restriction, of scarcity, dearness, and uncertainty. Any interference with the trade in corn, or with any other great department of trade, that has not the removal of natural or artificial restraints for its object, is not only inconsistent with the best established principles, but is sure to be pernicious. In this, as in all other things connected with national industry, the short and only safe rule is to leave individuals to pursue their own interest in their own way.

Our limits forbid our attempting to make any enumeration of the various statutes that have been passed at dif-

ferent periods for regulating the trade in corn. Down to the Revolution, the policy was to restrict exportation; but from that period the contrary policy has been pursued, and the legislature has pretty uniformly endeavoured to facilitate exportation, and to prohibit or fetter importation. It was not, however, till about 1770 that the restrictions on importation began to have much practical influence. But about that time, population having begun rapidly to advance, in consequence of the extraordinary impulse given to manufacturing industry by the inventions and discoveries of Watt, Arkwright, Wedgwood, and others, the price of corn in England began to rise above its price on the Continent; and from being an exporting we became an occasionally, or rather a pretty constantly, importing country. Had there been no restrictions on importation, our prices, it is plain, could not have exceeded those of the adjoining Continental states by a greater sum than might have been required to defray the cost of importing into this country. The restrictions, however, overturned this natural principle; and in deficient years added materially to the difference between our prices and those of the Continent. This difference attained to its greatest height during the late war, owing to the formidable difficulties it threw in the way of importation. During the last six years of that contest, prices in England (after allowing for the depreciation of the currency) were fully double their amount in the principal continental markets.

At the close of the war, in 1814 and 1815, the renewed intercourse with the Continent led to a great importation of corn, which occasioned such a sudden and heavy fall of prices as was productive of much severe distress amongst the farmers. Parliament endeavoured to obviate this by increasing the restrictions on importation, a device which had, in part, the anticipated effect. But since 1820, the influence of improved communications and of ameliorations in agriculture has been so very great, that, notwithstanding the vast increase of population, prices have been progressively falling, and were, in 1835, lower than in any previous year since 1787. Practically, therefore, the influence of the restrictions has been materially diminished, and a much greater effect is now usually ascribed to them in ordinary years than they really exert. No doubt, however, they tend materially to aggravate the scarcity and suffering originating in a deficient harvest, and are, therefore, highly objectionable.

The existing duty on foreign corn, or that imposed in the course of the present year (1842), by the act 5 Vict. 2 sess. cap. 14, is not invariable, but fluctuates according to the variations of price in the home market. It amounts to 20*s*. on wheat, when the price is at and under 51*s*. a quarter; and decreases, though not regularly, as the price rises, till the latter reaches 73*s*., when the duty is 1*s*. only. We subjoin the scale of duties on wheat: —

Average Price per Quarter.	Duty per Quarter.	Average Price per Quarter	Duty per Quarter.	Average Price per Quarter.	Duty per Quarter.
Under 51*s*.	20*s*.	58 — 59*s*.	14*s*.	66 — 67*s*.	6*s*.
51 — 52	19	59 — 60	13	67 — 68	6
52 — 53	18	60 — 61	12	68 — 69	6
53 — 54	18	61 — 62	11	69 — 70	5
54 — 55	18	62 — 63	10	70 — 71	4
55 — 56	17	63 — 64	9	71 — 72	3
56 — 57	16	61 — 65	8	72 — 73	2
57 — 58	15	65 — 66	7	73 and upwards	1

Corresponding duties are laid on barley, oats, and other species of grain.

This fluctuating scale of duty, though it be a material improvement on the previous scale, or that laid down by the act 9 Geo. 4. cap. 60, has like it, though in a less degree, the defect of adding to the risk and uncertainty incident to the corn trade; for, suppose a merchant orders a quantity of foreign corn when prices are at a certain level, if they fall before it arrives, he not only loses in consequence of the decrease of price, but is further charged with a corresponding increase of duty; whereas on the other hand, had the price advanced, he would have gained not merely by its increase, but by the fall in the rate of duty! The effect of this system is, therefore, precisely the reverse of what it should be were it founded on sound principles, inasmuch as it aggravates the loss arising from a bad, and increases the profit of a successful, speculation!

But in recommending the policy of a free trade in corn, we do not mean to contend that it would be either just or expedient always to admit of importation free of duty. In certain circumstances this may be the proper course, but not in all. No duty should ever be laid upon foreign corn on pretence of protecting British agriculture, as that is, in fact, taxing the other classes in order to secure a doubtful benefit for the agriculturists. But if agriculture be more heavily burdened than any other great department of industry carried on at home, a constant duty should be laid on corn from abroad, to balance the excess of duty falling on the agriculturists. This is not to favour the latter, but to do them justice. It has been denied that the British agriculturists are in this predicament; but were this the place for entering into such investigations, it would not be difficult to show that they are in fact more heavily taxed than the manufacturers or traders; and that, consequently, they are entitled to claim that a fixed and invariable duty be laid on all foreign corn when imported, corresponding to the excess of taxation by which they are affected. We believe, however, that a fixed duty of 5*s*. a quarter on wheat, and on other grain in proportion, would be more than adequate to meet all the claims of the agriculturists arising out of the peculiar pressure of the taxes to which they are subjected; and it is abundantly certain, that with such a duty, but little foreign corn would now be imported in ordinary years; and, consequently, that the agriculturists would sustain no real injury from the adoption of such a system. Those who may wish for further information as to the interesting topics now merely glanced at, and others we have not been able to notice, are referred to the article "Corn Laws," in the new edition of the *Encyclopedia Britannica*, the art. "Corn Laws" in the *Commercial Dictionary*, and the note on the same subject in M'Culloch's edit. of the *Wealth of Nations*, 1 vol. 8vo.

We subjoin an estimate of the quantity of corn used as food for man; and of the total quantity of corn produced and consumed in the United Kingdom, deduced from the data given in *M'Culloch's Statistics of the British Empire*, and the census of 1841.

	Quarters.
I. Consumed by man: —	
Wheat - - - -	15,000,000
Oats, rye, and maslin - - -	15,000,000
Barley for malting, &c. - -	6,000,000
Beans and pease as meal - - -	600,000
Total consumed by man - -	36,600,000
II. Consumed by the lower animals: —	
Corn (principally oats), used in the feeding of horses and other animals, in distillation, &c. - - -	18,000,000
Total consumed by man and the lower animals, &c. - - - -	54,600,000
To which add seed, 1-6th part -	9,100,000
Total growth of corn in the United Kingdom - - - -	63,700,000

Account of the Average Prices of British Wheat per Quarter, in England and Wales, since 1771, as ascertained by the Receiver of Corn Returns.

CO'RNEA. (Lat. cornu, *a horn.*) The transparent membrane of a horny texture which forms the anterior part of the eyeball. In vertebrates it is simple: in insects it is subdivided into numerous hexagonal segments.

CO'RNET. (It. cornetta, *a small flag.*) A commissioned officer in a troop of horse, corresponding in rank with the ensign of a battalion of infantry. His duty is to carry the standard near the centre of the front rank of the squadron.

Cornet. In Music, a shrill wind instrument formed of wood, which appears to have been in use in the earliest times, and remained so till about the commencement of the 18th century, when it was displaced by the oboe.

CO'RNET-A-PISTONS. (Fr.) A brass wind musical instrument, of the French horn species, but capable of much greater inflexion from the valves and stoppers (pistons) with which it is furnished, and whence it derives its name.

CO'RNICE. (Fr. corniche.) In Architecture, the upper great division of an entablature (*see* Entablature), consisting of several members.

CORNS. Thickenings of the cuticle of the toes, of a

horny texture, arising from continued pressure over a projection of bone. One of the best and simplest remedies for this painful disorder is to wear upon the toe or part affected a piece of leather, spread with diachylon or other emollient plaster, and having a hole in it corresponding with the size of the corn. By this means all pressure upon the corn is avoided. (See *Sir B. Brodie's Lecture on Corns and Bunions*, *Medical Gazette*, 13th Feb. 1836.)

CO'RNSTONE. A provincial name for a species of red limestone.

CO'RNU AMMONIS. A name sometimes applied to the fossil shells called Ammonites.

CO'RNUA. (Lat. cornu, *a horn.*) In Zoology, hard and more or less elongated processes projecting from the head. The term is usually applied to such processes in the class Mammalia, in which they serve as weapons of offence and defence. These weapons consist either of bone, when they are called "antlers;" or of horn, or of bone and horn, or lastly of bone and hairy skin. The first kind of horns are peculiar to the deer tribe; the second to the rhinoceros; the third to the sheep, ox, and antelope tribes; and the fourth to the giraffe. The bony horns, antlers, ceràta, or *cornua solida*, as they are technically termed, during the whole period of their formation resemble the horns of the giraffe, inasmuch as they are covered with a hairy and highly vascular integument: the bony material of these processes is in fact secreted by the vessels of that integument, so that their co-existence is essential as long as growth proceeds. When their growth is completed, and the antlers have arrived at their characteristic size and figure (which in the elk and Wapiti deer are truly remarkable), the determination of blood to the parts gradually lessens; the vessels shrink; the circulation in the formative membrane is at length suppressed; and the tegument then shrivels, dries, cracks, and is rubbed off by the instinctive actions which the deer now almost ceaselessly performs with his newly acquired and consolidated antlers. The skin and periosteum of the head, once continuous with those of the antler, now terminate at an abrupt line at the base of the antler, from which a ridge of bone, or "burr," as it is termed, is developed, apparently for the purpose of defending the margin of the persistent integument; for when this is continued, as in the Munt-jac deer, half way up the antlers, the burr is developed immediately above its termination, or at the middle, and not at the base of the antlers. Some physiologists have conjectured that the use of the "burr" was to compress the vessels of the periosteum of the antler, and that its formation was deferred to near the completion of the antler: but observation shows that it commences at an earlier period of growth; and sound physiology teaches that the cessation, like the commencement of the growth of the horn, must be the result of deeper and more constitutional operations. The most remarkable fact in the economy of antlers is that they are shed and renewed annually, the fall of the horns being concomitant with the shedding of the hair. The attempts to assign the final cause of this phenomenon have not been very successful. In the axis deer, *e. g.* the bucks do not all shed their horns at the same time, but at different periods of the year. In the rein-deer the branches which project forwards from the base of the horn, or the brow antlers, are habitually used to scrape away the snow which conceals the lichens on which they principally feed. The female, therefore, needs antlers as much as the male, and she has them; but this is a rare and singular exception, for the females of other species of deer are destitute of these ornamental weapons. True horns, or those which consist either partly or entirely of horny material, are never shed. In the antelopes they are in almost all cases confined to the male, and their bony basis is generally solid; in sheep and oxen the horns are commonly present in both sexes, and the bony basis is hollow. The term *cornua cava* is, however, usually applied to all horns consisting of bone and horn, and reciprocally the ruminants having such horns are termed "hollow-horned." But this extension of the term seems to have arisen from a consideration of the external horny sheath alone, which is but a part, and that not the most essential, of the horn. The horn or horns of the rhinoceros consist of an agglutination of horny fibres, which are attached only to the integument; the integument adhering with more than usual firmness at this part to the roughened surface of the bone beneath. The horn of the rhinoceros differs from that of other mammalia in being situated upon the median line of the forehead; so that when there are two they are placed one behind the other, and not laterally and symmetrically, as in the ruminants.

A few ruminants have naturally two pairs of horns; and this was the case with a great extinct species, *Sivatherium*, whose remains have been discovered in the Himalayan mountainous regions, where the small *Antilope quadricornis* still exists. Horns are characterized in zoological descriptions according to their position, as *Cornua nasalia*, *frontalia*, *parietalia*, &c.: or according to their direction, as *Cornua prona*, turned forwards; *reclinata*, turned back; *incurva*, bent inwards; *vara*, bent outwards; *redunca*, with the apices curved forwards; *lyrata*, when they represent the horns of the ancient lyre; *gyrata*, when spirally twisted: or according to their period of existence, as *cornua perennia*, when they last the life-time of the animal; or *cornua decidua*, or *annua*, when annually shed: lastly, horns are termed *cornua ossea*, *cornua solida*, *cava*, according to their structure, as above described. For the peculiarities of the giraffe's horns, see GIRAFFE.

Certain species of many other classes have parts projecting from the head, analogous in form or structure to the cornua of the mammalia. The frontal protuberance of the emeu, hornbill, and helmeted curassow consists of bone covered with a sheath of horn; the kamichi or horned screamer is a still more remarkable example of a bird so armed. In reptiles we find horned toads, vipers, and iguanas. Fishes present divers simulations of true horns. In mollusca retractile feelers or eye-stalks are commonly called "horns," as in the snail; but the appendages which would come under the general definition of our present term arrive at their maximum relative size, variety, and singularity of form in the class of insects.

CO'RNUCO'PIA. (Lat. cornu, *a horn*, and copia, *plenty.*) In the Fine Arts, an ornament representing a horn, from which issue flowers, fruits, leaves, and the like. The origin of the cornucopia has been variously given. Some authors have traced it to the infant days of Jupiter, whose nurse, Amalthea, when one of her goats had broken off a horn against a tree, presented it to the god wreathed with flowers and filled with fruit. Hence it became the emblem of Plenty among the ancients, in which light it is regarded also by many modern nations. The cornucopia is found very frequently in the types of ancient coins, particularly upon those of Sicily. (See the medal of Arsinoe.)

CORO'LLA. (Lat. corolla, *a garland.*) That envelope of a flower which is placed next within the calyx. It is usually more richly coloured and larger than the latter, but is extremely variable in this respect. Owing to its being in many plants one of the most striking parts of the flower, it is much employed by botanists in their systematical arrangements, and by the French school has been taken as the means of forming fundamental characters of the subclasses in the great Dicotyledonous division; but there is no doubt that its importance for this purpose has been much overrated. Theoretically considered, the corolla is composed of modified leaves, with the ordinary organization of which its parts or petals correspond as much as can be expected of rudimentary organs; its physiological action is to absorb oxygen, without decomposing carbonic acid, in which respect it agrees with leaves in their morbid state in the autumn. The corolla has been described by Lamarck as a diseased state of the foliage.

CO'ROLLARY. (Lat. corollarium, signifying originally a gratuity or donation presented to a person over and above what was strictly his due.) In its mathematical sense, this word is used to designate a consequence drawn from some proposition already demonstrated without the aid of any other proposition. Thus, supposing it demonstrated that if a triangle have two equal sides, it has also two equal angles; it would then follow, as a corollary, that if the three sides of a triangle are equal, its three angles are also equal.

CORO'NA. (Lat.) In Architecture, the flat, square, massy member of a cornice, very frequently called the drip or larmier. Its situation is between the cymatium above and the bed moulding below, and its use to carry the water drop by drop from the building.

CORO'NA AUSTRALIS and CORONA BOREALIS. (The *southern crown* and *northern crown.*) Two of the old constellations of Ptolemy; the first in the southern, and the second in the northern hemisphere.

CORO'NA DENTIS. In Zoology, the exposed part of a tooth, which projects beyond the alveolus and gum.

CORONA'MEN. In Zoology, the superior margin of a hoof, called in veterinary surgery the coronet.

CO'RONARY. (Lat. corona, *a crown.*) Coronary vessels and ligaments are those which spread round certain viscera, bones, &c.

CORONA'TION. *See* KING.

CO'RONER (Lat. coronator), is the title of an office established in Saxon times, of which the holder was, as his name indicates, in a peculiar manner the officer of the crown, whose private rights of property, whether arising by escheat, wardship, or consisting in demesne, it was his business to maintain and superintend in the county for which he acted. Connected in some degree with this character is the more important if not the sole function which he now exercises: that of holding inquests on the bodies of such as either die or are supposed to die a violent death. (4 Edw. 1. st. 2.) For which purpose he is empowered to summon jurymen out of the neighbourhood, and witnesses. Should violent death be occasioned by any personal chattel, it is forfeited as a deodand to the crown; but juries are now in the habit of assessing a small sum of money in lieu of the

chattel or its full value. (*See* DEODAND.) The coroner was originally in some sort the colleague and assistant of the sheriff, and in his default might still act as sheriff in the execution of writs, which in such case would be directed to him. The coroner is still, as the sheriff was formerly, elected by the freeholders of the county; but the office, which was once strictly honorary, has lost much of the dignity which belonged to it, and is now held by persons, usually either surgeons or attorneys, whose object in accepting it is the profit to be derived from fees. There are generally several coroners in the same county. (*Jervis on Coroners.*)

CO'RONET, or CORO'NA. This word is employed by botanists to express certain appendages of the corolla, which are arranged within it in a circle, and which not unfrequently give a very peculiar appearance to the flower in which it is found. In the Narcissus it is a cup; in Symphytum it consists of five glandular narrow processes; in Asclepias it is a thick fleshy ring extended into bended lobes. In all cases the coronet is a modification of sterile stamens.

CO'RONET. In Heraldry, an inferior crown belonging to the British nobility. The figure of John of Eltham, second son of Edward II., who died in 1334, affords the earliest representation of this ornament. Barons do not appear to have borne them earlier than the reign of Charles II. The time at which the coronets of the present orders of nobility were respectively distinguished in the existing fashion cannot be ascertained.

CO'RONET-BONE. The second of the consolidated phalanges of the horse's foot.

CO'RPORAL. (Fr. caporal, from capo, *a hedd.*) A non-commissioned officer in a battalion of infantry immediately under the serjeant; his business is to place and relieve the sentinels, and at drill he has charge of a squad. In the ranks he does the duties of a private, but his pay is somewhat higher.

CORPORA'TION. (Lat. corpus, *body.*) A body politic or incorporate; consisting of a person or persons having power to take and grant, &c. to himself or themselves and their successors. Corporations, in English Law, are divided,—1. Into sole and aggregate. Sole corporations are such as consist of a single person who is constituted a corporation by law, for the purpose of enjoying certain advantages and incurring certain duties, transmissible to his successors. Such is the parson of a living in respect of his benefice; a bishop, in respect of the ecclesiastical rights and property of his see; the king, &c. Corporations aggregate are such as consist of more individuals than one, and are kept up by a perpetual succession of members. 2. Into ecclesiastical and lay. Parsons, bishops, deans and chapters, are instances of the former. The latter are again subdivided into civil and eleemosynary. Among the first are trading companies and municipal corporations; among the latter, hospitals, colleges in the universities, and similar establishments (which, however, were anciently esteemed eccelsiastical).

By the law of England, corporations are erected only with the king's consent, express or implied; and may exist by prescription, by letters patent, or by act of parliament. Bishops, parsons, &c., may indeed be said to exist as corporations by force of the common law; but some ancient municipal bodies, such as the corporation of London, are in a stricter sense corporations by prescription. Corporations by act of parliament may be created either expressly, or by implication; as, where a body is to take lands by succession, this constitutes them a corporation. But the ordinary mode by which they are erected is by the king's letters patent or charter of incorporation; persons exercising the power of founding corporations by a grant of their own (as the chancellor of the university of Oxford) being for this purpose only delegates of the king.

The chief incident of a corporation is the power of taking by succession. This power is, however, confined in the case of sole corporations to estates of freehold; corporations aggregate only can take goods and chattels by succession. Grants by a corporation aggregate must be by deed under their common seal, which is necessary to give validity to most of their acts. A corporation has essentially the power of making by-laws to bind its own members, which are valid so far as they are not contrary to the laws of the kingdom. Corporations ecclesiastical and eleemosynary may, moreover, be subject to rules or statutes imposed by the king or the founder; civil corporations only to the common law and their own by-laws. In aggregate corporations, the act of the majority is the act of the whole.

The common law capacity of corporations to take lands has been, however, materially narrowed by statute. Thus a devise of lands to a corporation by will is bad, except for charitable purposes. And, in consequence of the Statutes of Mortmain (*see* MORTMAIN), a corporation, whether lay or ecclesiastical, must now have a license from the king in order to purchase.

All corporations are said to be subject to visitation. The visitor of ecclesiastical corporations is the ordinary (*see* ORDINARY); the visitor of lay corporations is the founder. In eleemosynary corporations this right, therefore, is in the founder and his heirs, or in such person as he has appointed: in civil corporations, the king is visitor, and exercises that jurisdiction in the King's Bench; where alone misbehaviour of such corporations or their officers can be inquired into, chiefly by means of the processes termed *mandamus* and *quo warranto* (which see). A corporation is dissoluble, 1. By act of parliament; 2. In the case of an aggregate corporation, by the death of all its members; 3. By surrender of its franchises into the hand of the king; 4. By forfeiture of its charter through negligence or abuse of the franchise.

CORPORA'TIONS, MUNI'CIPAL. These bodies, which have acted so important a part in the history of modern Europe, originated in the Italian and provincial towns subject to the Roman sway. Under that empire the government of the towns was in many respects independent of the central authority, or only controlled by it in the last resort; and as the municipal institutions of the Romans remained undestroyed through the long period of the dark ages, the free cities which arose in the eleventh and twelfth centuries in Italy, France, and elsewhere, did in fact only preserve their ancient systems of internal policy in the new character of republican constitutions. (See especially *Savigny on Roman Jurisprudence in the Middle Ages.*)

In England we have no record of the internal constitution of our towns prior to the Saxon times, and during those times our information is extremely scanty and imperfect. The magistracy in Saxon towns appears to have been elective; that in Danish, hereditary. In Domesday Book we find in every town (eighty-two in all, in those parts of the record which remain to us) a certain number of persons mentioned as "burgesses;" a number sometimes equalling, sometimes falling far short of the houses enumerated. It has been supposed that at this early period all free inhabitants paying scot and lot were burgesses; a supposition which can neither be easily proved nor controverted. Boroughs at this period were exempt from the immediate jurisdiction of the sheriffs of the counties in which they were situate: they possessed their own hundred courts, leets, and view of frankpledge; but they were liable for various duties to the king, who was usually lord of the leet, *i. e.* exercised jurisdiction in the borough; and to the lord of the soil also, if there were any. It became usual after the Conquest for the king to let the fees and revenues thus due, together with the right of appointing the officers of justice, to the burgesses in general; and by this species of enfranchisement the borough became an independent municipality. But a free borough was constituted by having, in addition to those powers, exemption from the king's tolls, granted to its burgesses by royal charter. Such continued to be, in substance, the condition of English boroughs for several centuries. Burgess-ship was gained, either by residence simply, with payment of scot and lot, or, in some cases, by apprenticeship, constituting a title of admission to the guild merchant or trading community of the borough, which by degrees became identified with the borough itself; or, as in London, by admission into the guilds of the several trades, an alteration which appears to have taken place in that city as early as the thirteenth century.

During all this period no one seems to have doubted the capability inherent in the burgesses of a town, as a community, to take and enjoy lands, tolls, or other hereditaments, to themselves and their successors. But about the period of the reigns of Henry V. and VI., the increasing subtlety of our legal system, and more particularly the notions introduced by the study of the civil law, appear to have occasioned the custom of granting charters in a new form. It appears to have been thought that the power of holding lands in succession, and the right of suing and being sued by a common name, could not in strictness be enjoyed, except by a body constituted for those very purposes by the king's grant. Hence originated charters or letters of incorporation. These seem to have been first granted to eleemosynary foundations; afterwards, and first in the reigns before mentioned, they were granted to the men or burgesses of towns jointly with the mayor, bailiff, or other chief officer; and thus municipal corporations in the strict legal sense were first constituted.

But previously to this time it is probable that a great change had taken place, in most towns, in the character of the class of "men" or "burgesses" to whom these charters were granted. As the privileges of burgess-ship became more valuable, additional difficulties were thrown by the governing body in the borough in the way of its acquisition. While the old household right remained in some places, it was lost in others: in its stead, or by its side, arose the rights of freemen of a guild or trade; those of the holders of particular tenements, which alone were recognized as conferring on their occupant the title of burgess; those of freeholders in cities, counties of themselves, &c. And hence the variety of the old parliamentary franchise (*see* PARLIAMENT), as members of parliament were elected by the burgesses. Hence the

corporations, which were constituted by the charters of Henry VI. and Edward IV., were already very different bodies from the general mass of dwellers in a town. But close corporations, properly so called, were not established until the reigns of the Tudors, when the first "governing charters" were granted; that is to say, charters which, disregarding the old common law system, by which every burgess had a share in corporate rights, and the power of electing his magistrates, established special rules for the internal regulation of a borough. By these new charters the powers of municipal government were usually vested in a mayor and common council: the latter consisting of councillors and aldermen; the former of whom were selected in various ways, by the whole of the council or the aldermen; the aldermen mostly nominated by and out of the rest of the council. In these bodies the control over the town funds, the civil and criminal jurisdiction of the town, and police authority within its limits, became vested. The freemen, as well as the commonalty, thus ceased to be members of the governing body; but the former retained the extensive pecuniary advantages which in many places belonged to them.

The causes of this revolution, and of the gradual change by which the municipal bodies became more and more exclusive in their character, are chiefly to be found in the parliamentary franchise enjoyed by most of the corporate boroughs. When the House of Commons became an important body in the empire, the crown, as well as the noblemen and the powerful individuals to whose estates the boroughs were contiguous, had a strong and direct interest in controlling the nomination of members. This was much more easily effected by the agency of select bodies, such as the corporations, than by influencing the votes of an independent community. Hence, while in the larger places the corporation, usually devoted to the interest of its patron, exercised a decisive or a strong authority in controlling elections, in many smaller boroughs the elective franchise became in effect confined to the corporation itself, by means of the freemen who were closely associated with it. Thus the system of close corporations, established under the Tudors, acquired continually more strength and more exclusiveness: although the committee of privileges presided over by Mr. Serjeant Glanville, in the reign of James I., resolved that charters of the crown were inoperative so far as they assumed to alter the parliamentary franchise of a borough. The governing bodies in the previous reign seem also to have assumed in many places the power, which has been since so liberally exercised, of admitting to the rights of freemen, or burgesses, whom they pleased, either by free gift or purchase. The great bulk of the property of corporations, both that enjoyed by them to their own use, and that of which they were trustees for charitable purposes, seems to have been acquired after the first charters of incorporation were granted, and previously to the Revolution.

In the reign of Charles the Second, when the corporate bodies in the larger towns had become for the most part attached to the Whig interest, and hostile to the court, they were attacked by the crown through the famous writs of quo warranto. These were writs issued out of the King's Bench to the municipal bodies, to inquire by what right they exercised their jurisdictions and enjoyed their franchises; and the object was to contest the validity of the ancient charters, or at least to terrify them into surrendering them into the king's hands, and receiving new ones from him. Many such surrenders were actually made, and new charters granted: these, however, were recalled by a proclamation of James II., and the old ones regranted or revived; and this proclamation was allowed, after the Revolution, to have the force of law. A few boroughs, however, did not accept the restoration of their charters, and remained without a corporation. From the period of the Revolution little or no change of importance took place in the constitution of the towns or their governing bodies, until the passing of the Municipal Reform Act in 1835. By this act (5 & 6 W. 4. c. 76.) the municipal franchise is made uniform all over the kingdom. In order to enjoy it, an individual must have occupied a house, warehouse, counting-house, or shop, within the borough, for three years; and must have been rated to all poor rates in respect of such premises during the whole of such time; and must be enrolled on the burgess list, which is framed by the overseers of the parishes and revised every year by the mayor and assessors. He must also have resided within seven miles of the borough during that time. There are also provisions for the cases of successive occupancy and change of residence. These burgesses form the electoral body. They choose,—1. The councillors; of whom the number is limited by the act, according to the number of wards of which each borough consists (this number being also specified by enactment, and varying from one to sixteen). No person can be qualified as a councillor, or alderman, unless he is a burgess possessing a certain amount of property (1000*l.*), or a rating at 30*l.* per annum, in boroughs having four wards and upwards; 500*l.*, or 15*l.* per annum, in boroughs not having that number. One third part of the councillors go annually out of office. 2. The council, *i. e.* the mayor, existing aldermen, and councillors, jointly elect every year the aldermen from among the qualified burgesses; half of whom go out of office every third year. 3. The councillors and aldermen together elect out of their own united body the mayor, whose office is annual. The mayor, aldermen, and councillors together form the council. The town-clerk, treasurer, &c. are appointed by the council during pleasure.

With regard to existing rights, freemen are retained, so as to enjoy their rights of property and parliamentary franchise; but they can no longer be made by gift or purchase; and they must be inhabitants of the borough. The income arising out of the corporation property is to form a borough fund; which is to be applied, subject to existing claims, to the payment of salaries and other municipal expenses, prosecutions, maintenance of the gaol, &c. &c.; and if the fund be insufficient for these purposes, the council can impose a rate to supply the deficiency. Wherever a municipal corporate body, either sole or in conjunction with other persons, had lands, &c. in trust to charitable uses, the trusts are gradually transferred by this act to the new councils; but every corporation possessed of advowsons, or rights of nomination to benefices in the church, is required to sell such advowsons, &c. under the direction of the ecclesiastical commissioners. Where the watching of the town was regulated by local acts, these acts are repealed, and the corporation is directed in all places to appoint a committee for the purpose of superintending that duty; and wherever the lighting is not regulated by local acts, that also is placed under the management of the corporation.

With respect to jurisdiction, the council of every borough now having a separate court of quarter sessions, or desiring to attain one, may apply to the king to retain or to acquire it; on which the king may, if he pleases, appoint a recorder to be paid by the town, being a barrister of five years' standing. This officer is to hold the court of quarter sessions of the peace, in which he is to be sole judge. Borough courts of record are to be retained as heretofore, and those in which a barrister of five years' standing acts as judge have power to try personal actions to the amount of 20*l.* The king is empowered to grant a commission of the peace to all boroughs named in Schedule A of the act, and to such boroughs named in Schedule B as he shall see fit, on petition of their council. The mayor and recorder to be justices of the peace ex officio; the others named by the crown. The council also are directed, if they think fit, to petition for the appointment of salaried police magistrates in their borough, stating the salary which they are willing to pay; on which the crown will appoint such officer or officers, being barristers of not less than five years' standing. The history of municipal corporations has been often written, and generally with much party spirit and unfairness. Those who wish to study it in the only authentic records, viz. charters and other documents, will find the most abundant collection of them, chronologically arranged, in *Messrs. Merewether and Stephen's History of Boroughs*, 1836.

CORPU'SCULA VERMIFO'RMIA. (Lat. corpusculum, diminutive of corpus, *body*, and vermiformis, *worm-shaped.*) In Vegetable Anatomy, are synonymous with strangulated or necklace-shaped ducts, a kind of spiral vessel found chiefly in the knots and contracted parts of stems.

CORPU'SCULAR A'CTION. The power or influence which the minute particles, or atoms, or *corpuscles* of matter, exercise on each other, and which is the cause of all chemical changes.

CORPU'SCULAR PHILO'SOPHY. A system of physics in which all the phenomena of the material world are explained by the arrangement and physical properties of the corpuscles or minute atoms of matter. A doctrine of this sort was anciently taught in Greece by Leucippus and Democritus, and is described in the beautiful poem of Lucretius.

CO'RPUS JURIS. (Lat. *body of law.*) *Corpus Juris Romani*, the collection of the authentic works containing the Roman law as compiled under Justinian. The Corpus Juris comprehends the Pandects, the Institutes, the Code, and the Novels or Authentics, *i. e.* the later constitutions of Justinian; to which, in some editions, are added a few issued by his successors. M. Beck has lately published at Leipzig the most complete edition. There are likewise publications styled *Corpus Juris Canonici*, *Germanici*, *Feudalis*, &c.

CORRE'CTION. (Lat. corrigo, *I correct.*) In the Fine Arts. With the Italians the word, *correzione*, is used to denote an exact acquaintance with the different proportions of the parts of a body or design generally; but with us the term is applied to those emendations of inaccuracies or alterations of first thoughts, which they call *pentimenti*, to be seen under the surface of the finished picture, and which are accounted indications of its originality.

CORRECTING, in Printing, in the first instance, is to amend and put right the errors in the types that the compositor may have made, and any defects in his workmanship; in the next, it is the correcting of the proof sheets of a work by the author or editor, in the orthography, the punctuation, the language, and in making such alterations as may appear to him necessary. The following explanation of the marks which are in general use by printers for this purpose, with the annexed specimen, will enable a gentleman who has to superintend a work through the press to correct the proof sheets in a way that will be clearly understood by the printer, and will tend to promote correctness by preventing those mistakes that occasionally occur, owing to his not clearly comprehending the marks on the proof.

1. Where a word is to be changed from small letters to capitals draw three lines under it, and write *caps.* in the margin.

2. Where there is a wrong letter draw the pen through that letter, and make the right one opposite in the margin.

3. A letter turned upside down.

4. The substitution of a comma for another point, or for a letter put in by mistake.

5. The insertion of a hyphen.

6. To draw the letters of a word close together that stand apart.

7. To take away a superfluous letter or word the pen is struck through it and a round top *d* made opposite, being the contraction of *deleatur*, to expunge.

8. Where a word has to be changed to Italic draw a line under it, and write *Ital.* in the margin; and where a word has to be changed from Italic to Roman, write *Rom.* opposite.

9. When words are to be transposed three ways of marking them are shown; but they are not usually numbered except more than three words have their order changed.

10. The transposition of letters in a word.

11. To change one word for another.

12. The substitution of a period or a colon for any other point. It is customary to encircle these two points with a line.

13. The substitution of a capital for a small letter.

14. The insertion of a word, or a letter.

15. When a paragraph commences where it is not intended, connect the matter by a line, and write in the margin opposite *run on.*

16. Where a space or a quadrat stands up and appears, draw a line under it and make a strong perpendicular line in the margin.

17. When a letter of a different size to that used, or of a different face, appears in a word, draw a line either through it or under it, and write opposite *w.f.*, for wrong fount.

18. The marks for a paragraph, when its commencement has been omitted.

19. When one or more words have been struck out, and it is subsequently decided that they shall remain, make dots under them, and write the word *stet* in the margin.

20. The mark for a space where it has been omitted between two words.

21. To change a word from small letters to small capitals make two lines under the word, and write *sm. caps.* opposite. To change a word from small capitals to small letters make one line under the word, and write in the margin *lo. ca.* for lower case.

22. The mark for the apostrophe; and also the marks for turned commas, which designate extracts.

23. The manner of marking an omission, or an insertion, when it is too long to be written in the side margin. When this occurs it may be written either at the top or the bottom of the page.

24. Marks when lines or words do not appear straight.

The subjoined specimen when corrected would be as follows:—

ANTIQUITY, like every other quality that attracts the notice of mankind, has undoubtedly votaries that *reverence* it, not from reason, but from prejudice. Some seem to admire indiscriminately whatever has been long preserved, without considering that time has sometimes co-operated with chance: all perhaps are more willing to honour past than present excellence; and the mind contemplates genius through the shades of age, as the eye surveys the sun through artificial opacity. The great contention of criticism is to find the faults of the moderns, and the beauties of the ancients. While an author is yet living, we estimate his powers by his worst performances; and when he is dead, we rate them by his best.

To works, however, of which the excellence is not absolute and definite, but gradual and comparative; to works, not raised upon principles demonstrative and scientifick, but appealing wholly to observation and experience, no other test can be applied than LENGTH of duration and continuance of esteem.

Antiquity, like every other 1 *caps*
quality that attr~~r~~cts the notice

we rate them by his best. 23

CORRESPO'NDENCE. (Lat. con, *with*, and respondeo, *I answer*.) In the Fine Arts, the fitting or proportioning the parts of a design to each other, so that they may be correlative, and that the same feeling may pervade the whole composition.

CO'RRIDOR. (Ital. corridoro.) In Architecture, a gallery or open communication to the different apartments of a house.

CORRO'SIVE SUBLIMATE. The bichloride of mercury, composed of 200 mercury + 72 chlorine. It is an acrid poison of great virulence: the stomach-pump and emetics are the surest preventives of its deleterious effects when accidentally swallowed; white of egg has also been found serviceable in allaying its poisonous influence upon the stomach. Its specific gravity is 52. It requires 20 parts of cold water, but only 2 of boiling water, for its solution. *See* Mercury.

CO'RRUGATE. (Lat. ruga, *wrinkle*.) In Zoology, the surface of an animal is so called when it rises and falls in parallel angles more or less acute.

CO'RSAIR. (Ital. corsaro.) A term used in the south of Europe and some other parts for a pirate or his ship. The corsairs of Barbary were commissioned by their princes to attack the merchant ships of hostile countries.

CO'RTES. (*See* States.) The old assembly of the estates in Leon, Castile, Arragon, and Portugal. These estates were framed, as elsewhere, of nobility, dignified clergy, and representatives of the towns. In Arragon they were presided over by a high officer, termed Justiza, with powers in some respects sufficient to control the monarch. The origin of popular representation in the cortes of the several kingdoms out of which that of Spain was finally formed is assigned to a date as early as the 12th century; but the deputies sent by the towns were irregularly summoned, frequently did not attend, and the numbers which appeared for each town frequently bore no proportion to the relative size of the different places. In the 14th century the power of the cortes seems to have been at its height, after which it gradually decayed, and under the government of Ferdinand and Isabella was reduced almost to a nullity. (See *Prescott's Ferdinand and Isabella*, vol. i.; *Hallam's Middle Ages*.) After the time of Philip II., the cortes of Spain were only occasionally convoked on the accession of kings, and their sittings were a mere form. In 1811, during the French invasion, they were convoked at Cadiz, and conducted the affairs of that kingdom during the war of independence. In 1814, Ferdinand VII. dissolved them, and declared all their decrees null. In 1820, the cortes met again, and adopted a new constitution; in 1821, the people of Portugal followed the same example: both constitutions were overthrown in 1823; the first by the French invasion, the latter by a counter revolution. The later events of Spanish and Portuguese history have again called these national assemblies into existence.

CORTI'CIFERS, *Corticiferi*. (Lat. cortex, *bark*, fero, *I carry*.) Those Polyps whose uniting fleshy substance is spread, like the bark of a tree, over a central calcareous or corneous axis.

CO'RTILE. (Ital.) In Architecture, an open quadrangular or curved area in a dwelling-house, surrounded by the buildings of the house itself.

CO'RTINA. (Lat. cortina, *a kind of table*.) A term used in describing Fungi, to denote that portion of the velum which adheres to the margin of the pileus in fragments.

CORU'NDUM. A crystallized or massive mineral of extreme hardness, and composed of nearly pure alumina; it is usually almost opaque, and of a reddish colour. It is allied to the sapphire.

CORVE'E. (French.) In Feudal Law, the obligation of the inhabitants of a district to do certain services, as the repair of roads, &c. for the sovereign or the feudal lord. Some species of corvée were performed gratis; others for a fixed pay, but generally below the value of the labour performed.

CO'RVUS. (Lat. *the raven*.) A Linnæan genus of birds, now the type of a family (*Corvidæ*), belonging to the Conirostral division of the *Passeres* of Cuvier; and including, with the Crows proper, the Rollers (*Coracias*) and Birds of Paradise (*Paradisea*).

Co'rvus. In Astronomy, one of Ptolemy's constellations, in the southern hemisphere.

CORYBA'NTES (Gr.) in Grecian Mythology, were the priests of Cybele; so called either from Corybas, the son of that goddess, or from the frantic gestures with which their devotions were accompanied; the term Corybantes signifying literally "shaking the head violently." They used to beat brazen cymbals in their sacred rites;

—— Acuta
Si geminant Corybantes æra. Hor. *Od.* I. 16. 8.

and their whole religious proceedings were characterized by such extravagant fanaticism as to have enriched the Greek language with several terms expressive of *madness* or *frenzy*.

CORYCE'UM. (Gr. κώρυκος.) In Ancient Architecture, an apartment in a gymnasium whose exact destination is not known.

CORYDA'LEA. An alcaline principle, from the *Corydalis tuberosa* and *Fumaria cava*.

CO'RYMBI'FERÆ. (Lat. corymbus, *a flat-headed kind of inflorescence*, and fero, *I bear*.) One of the divisions of the great group of *Compositæ* admitted by Jussieu. It comprehends those plants which, like the Chrysanthemum and the Aster, have the capitula furnished with a ray; and those others which, like Artemisia, although destitute of a ray, are similar to such plants in the majority of their characters.

CORY'MBUS. (Lat.) In Ancient Sculpture, the cluster of ivy leaves, berries, garlands, &c. with which vases were encircled.

Cory'mbus. In Botany, a form of inflorescence consisting of a central axis, developing lateral pedicels, the lower ones of which are so long that their flowers are elevated to the same level as that of the uppermost.

CORYPHŒ'NA. (Gr. κορυς, *a helmet*, and φαινω, *I show*.) A genus of spiny-finned fishes, so called from the head being crested like a helmet. It belongs to the Mackerel family (*Scomberoids*); and includes the true dolphin, or changeable coryphene (*Coryphœna hippuris*). The genus is now raised to the rank of a family, including, with *Coryphœna* proper, the subgenera *Centrolopus* and *Leptopodes*.

CO'RYPHŒ'US. (Gr. κορυφη, *summit*.) The leader of the chorus in ancient dramas; by whom the dialogue between the chorus and the other actors of the drama was carried on, and who *led* in the choric song.

CORY'ZA. (Gr. κορυζα.) A copious running from the nose.

CO'SECANT and COSINE. The secant and sine of the complement of an angle or arc; the prefix *co* being merely the abbreviation of *complement*, first introduced by Gunter.

COSME'TIC. (Gr. κοσμεω, *I adorn*.) Remedies to remove freckles and pimples from the face and to improve the complexion.

CO'SMICAL. (Gr. κοσμος, *the world*.) This word occurs frequently in the ancient astronomy, in which it is used to denote a particular position of a planet or star, at its rising or setting, in respect of the sun. A star is said to rise *cosmically* when it rises at the same instant that the sun rises; and to set cosmically, when it sets with the sun. Cosmical is opposed to *achronycal*, which signifies that a star rises at the instant the sun sets, and vice versâ. The cosmical and achronycal risings of a star are invisible to the naked eye, because the light of the sun in the horizon effaces that of the star.

COSMO'GONY. (Gr. κοσμος, *world*, and γονος, *birth*.) The science which treats of the origin of the universe. If we except the cosmogony of the Indians, the earliest extant is that of Hesiod, which is delivered in hexameter verse. The first prose cosmogonies were those of the early Ionic philosophers, of whom Thales, Anaximenes, Anaximander, and Anaxagoras are the most celebrated. In modern times, a Theory of the World has been produced by Burnet. We do not include in this list of cosmogonies the researches of modern geologists, or the systems to which they have led. They may be said to hold the same place in relation to the old cosmogoners, which the astronomer or the chemist occupies in reference to the astrologers and alchemists of ancient times.

The different theories which have been formed to account for the origin of the world may be comprehended under three classes: — 1st, Those which suppose the world to have existed from eternity under its actual form. Aristotle embraced this doctrine; and conceiving the existing universe to be the eternal effect of an eternal cause, maintained that not only the heavens and the earth, but all animate and inanimate beings are without beginning. 2d, Those which consider the matter of the universe eternal, but not its form. This was the philosophical system of Leucippus, Democritus, Epicurus, and indeed most of the ancient philosophers and poets, who feigned the world either to be produced by the fortuitous concourse of atoms existing from all eternity, or to have sprung out of the chaotic form which preceded its present state. 3d, Those which ascribe both matter and its form to the direct agency of a spiritual cause.

COSMO'GRAPHY. (Gr. κοσμος, and γραφω, *I write*.) The science which treats of the construction, figure, and arrangement of all the parts of the world; and therefore comprehends astronomy, geography, and geology.

COSMO'LOGY. (Gr. κοσμος, and λογος, *a discourse*.) *See* Cosmogony.

COSMO'POLITE. (Gr. κοσμος, and πολις, *a city*.) A citizen of the world: one who makes the world his country.

COSMORA'MA. (Gr. κοσμος, and ὁραω, *I see*.) A species of picturesque exhibition, consisting of a number of drawings, generally about eight or ten, which are laid horizontally round a semicircular table, and reflected by

mirrors placed opposite to them diagonally. The spectator views them through a convex lens placed immediately in front of each mirror. The pictures are illuminated by lamp light; but the lamps are so placed that they cannot be reflected by the mirrors, and are therefore invisible to the spectator.

COSS. When algebra was first introduced into Europe, it was called the *Rule of Coss;* probably from the Italian *Regola di Cosa*, the *Rule of the Thing;* the unknown quantity being termed *cosa*, the thing. Hence *Cossic Art, Cossic Numbers*, &c., found in some of the old authors.

COSSA'CKS. A people inhabiting those parts of the Russian empire which border on the northern dominions of Turkey, Poland, and the southern confines of Siberia. Both the name and origin of this people are involved in great uncertainty. They seem to have nothing Russian in their origin and character, and are probably a mixed Caucasian and Tartar race. They form a sort of independent republic, paying no taxes to Russia, but cheerfully contributing their numerous and valuable contingent of troops; and are well known as the most harassing light troops that ever exercised a predatory warfare in the train of any army.

Their dress is a short vest in the Polish style, large trowsers of a deep blue colour, and a black sheepskin cap. Their arms consist of a sabre, long spear, musket, a pair of pistols, and a long whip, which they apply to their enemy as well as their charger's back. They are mostly members of the Russian Greek Church, and are described as a hospitable, generous, and disinterested people. Their numbers have not been estimated for nearly a century, when they amounted to 955,228 males.

CO'STA. (Lat. costa, *a rib.*) A term formerly confined to that bundle of vessels which passes directly from the base to the apex of a leaf; but which is better extended to all the main veins which proceed directly from the base to the apex, or to the points of the lobes.

CO'STAL. (Lat. costa.) Belonging to the ribs.

CO'STARDMO'NGER. (From costard, *a large apple.*) An itinerant dealer in apples. The word is often written *costermonger*, and applied to hawkers and pedlars who sell fruit.

CO'STATE. (Lat. costa, *a rib.*) In Botany, a term applied in two ways, in describing the venation of leaves: either to indicate the presence of but one rib, as in most leaves; or in speaking of cases where three or more ribs proceed from the base to the apex of a leaf, and are connected by cross veins. The latter are frequently called nerves, or nervures. If a leaf has its ribs all distinct from the very base, it is called tricostate, quinquecostate, and so on; but if the ribs are united at the base in a distinct manner, the term becomes triplicostate, quintuplicostate, &c.

COSTATE. In Zoology, the surface of the whole or part of an animal is so termed when it has several broad elevated lines.

COSTS. In Law, the expenses to which parties are put in the prosecution and defending of actions. Costs are to be considered either as between attorney and client, *i. e.* the expenses and fees which the attorney is entitled to recover from his client; or as between party and party, *i.e.* that portion of the expenses to which a successful party has been put in his suit, which he is entitled in certain cases to recover from the unsuccessful one. Costs in the latter sense are not given by the common law. The statute of Gloucester (6 E. 1. c. 1. s. 2.) first enacted, that the demandant should recover from the tenant the cost of his writ, if successful; and that this provision should extend to all cases where a man recovers damages. By a liberal construction of this statute the costs of the writ are understood as the costs of the action, and its benefit is extended to plaintiffs in most cases where they would have been entitled to damages before that statute. In other cases, the plaintiff is not entitled to costs, unless they are expressly given by statute. In assumpsit, covenant, and debt, if the plaintiff have a verdict, but the damages or debt and damages be under 40*s*., the judge may deprive him of any more costs than damages by certifying to that effect on the record, under 43 Eliz. c. 6. s. 2. In actions for assault and battery, and trespass, wherever the damages given by a jury do not amount to 40*s*., the plaintiff (by several statutes) is allowed no more costs than damages, unless the judge shall certify that assault and *battery* was sufficiently proved; or, in trespass, that the title to land came in question. The certificate may be granted at the trial, or within a reasonable time afterwards. Where, out of several issues, some are found for the plaintiff and others for the defendant, the plaintiff is now only entitled to costs on those issues on which he may succeed, and the costs of the defendant's issues will be deducted from his. The defendant's right to costs rests also on several statutes, principally 23 H. 8. c. 15. Double and treble costs are given by some statutes in particular cases; and they follow by implication where double and treble damages are given. Double costs, in practice, mean single costs and one half their amount in addition: treble, the same, with one half of these last. Costs are *taxed* as between party and party by officers of the court; and recoverable by action, execution, or attachment. As between attorney and client, the attorney has a right of action for costs; but his bill is liable to taxation by officers of the court, under certain restrictions. Costs in equity are within the discretion of the court, except in certain cases; as where no answer is made to a bill exhibited, or an insufficient answer, &c.

COSTU'ME. (It.) In Painting and Sculpture, this word has become used chiefly as a term denoting the particular sort of dress suitable to the subject, according to the time in which the action is supposed to have taken place; but the word has a more general signification, inasmuch as it includes the keeping of all the accessories, ornaments, utensils, &c. of such forms and colours as historical knowledge proves them really to have possessed.

COTE' DROIT, COTE' GAUCHE. *See* DEPUTIES, CHAMBER OF.

COTERIE. An old French word, supposed to be derived from the Lat. quot, *how many*, signifying literally a society or company. In the 13th or 14th century, when merchants were about to embark in any commercial enterprise, they formed a coterie or company, each contributing his *quota* of goods or money, and deriving his *quota* of profit. But the term soon acquired a more extended signification, in which, however, the original meaning is still perceptible, being applied to any exclusive society in which interesting subjects (chiefly literary and political) are discussed, each member being supposed to contribute his *quota* or share of information for the general edification or amusement.

COTI'SE. (Fr. coté, *side.*) In Heraldry, a diminutive of the bend, being one half the width of the bendlet: generally borne in couples, with a bend or charges between them. A bend, fess, &c. between two cotises, is termed *cotised.*

CO'TTABUS. (Gr. κοτταβος.) A celebrated Greek game. It consisted in throwing wine from cups into little basins of metal suspended in a particular manner, or floating in a large vessel of water; so that dexterity might be shown in throwing it without spilling, in producing a particular sound, &c. The cottabus was so favourite a sport, that rooms were built expressly for its performance, styled *cottabeia.*

CO'TTAGE ALLO'TMENTS, are those portions of ground which are allotted to the dwellings of country labourers for the purpose of being cultivated by them as gardens. Sometimes these allotments are placed adjoining the dwellings, in which case they are more commonly called cottage gardens; but at other times they are placed at a distance from the cottage, and form small portions of a large enclosure; and to this kind of cottage garden the term allotment is more properly applied than to the other. The object in both cases is to afford resources to the cottager; and to enable him, by growing vegetables and roots of various kinds, not only to supply his own family, but to keep pigs, rabbits, poultry, &c. Such being the uses of cottage allotments, the advantage of each cottage having its garden surrounding it, instead of at a distance, is sufficiently obvious. In the latter case, the cottager must necessarily lose much time in travelling backwards and forwards from his house to his garden; and his wife and children will often be prevented from employing themselves in it. In such a garden he cannot grow fruits, because they would be comparatively unprotected; nor can it be worth his while to grow flowers in a place where they would not prove an ornament to his dwelling. On the supposition that the cottager has his pigstye close to his dwelling, the food for the pigs must be brought home from the allotment; and the manure made by them, which is one of the advantages of keeping pigs, must be carried out again. It is well known to all persons of any experience on this subject, that by far the most valuable part of the manure made by the cottager, such as soapsuds, &c., may be included under the term liquid manure; and this, when the allotment is at a distance, may be considered as entirely lost, the cottager being without either conveniences or time for carrying it out. In point of usefulness, therefore, a cottage allotment in a field, at the distance of a furlong or less from the cottage, is not worth half what it would be if adjoining the dwelling; while in point of enjoyment to the cottager, and of ornament to the roadside, it is hardly worth anything. A cottage allotment is therefore a miserable substitute for a cottage garden. On the other hand, the labourer who has a lease of a comfortable cottage surrounded by a garden, even if the latter should not be larger than the eighth part of an acre, has within his reach all the essentials of happiness possessed by the richest landed proprietor. He can grow good and wholesome vegetables and fruits; he may have his live stock of pigs, poultry, rabbits, and bees; he may ornament his house front, and the borders of his walk with shrubs and flowers; and he has the wages of his labour

for the purchase of those comforts and luxuries which his garden does not afford. In the culture and management of this spot, he has constant occupation of the most agreeable and useful kind for his leisure hours throughout the year; and, in short, whatever the farmer or country gentleman has on a large scale, he has on a small one. In quiet possession of this little garden, which he regards as his own, he learns to respect himself, acquiring at the same time a taste for accumulating property. The time, it is to be hoped, is not far distant when the humblest country labourer will possess such a cottage and garden; but it is necessary that the country labourer should acquire previously a taste for these comforts by seeing them possessed by others of his class; and for this we must look partly to the country labourers themselves, partly to the government for the establishment of a system of universal education which shall raise the taste of the humblest part of society, and partly to the humanity and sympathetic feeling of the landed proprietors; because it is to them we must look, in the first instance, for building the cottage and accompanying it with garden ground.

COTTON. (*Gossypium*, Lin.) A species of vegetable wool, the produce of the *Gossypium herbaceum*, of which there are many varieties. The kinds of cotton met with in the market are usually designated by the names of the places from which they are brought; but practically, they are all divided into the two great classes of *long and short stapled*. Its goodness depends on its colour, and the length, strength, and fineness of its fibre. Its price varies, according to quality, from 2*s*. to 4*d*. per lb. The general chemical characters of cotton are those of *lignin*. It is peculiarly susceptible of combination with certain metallic oxides or bases; whence the facility with which it is locally dyed, as in the process of *calico printing*.

COTTON MANUFACTURE. In modern times cotton has attained to an importance among vegetables second only to that of corn, and which could not have been so much as dreamed of in former ages. The manufacture of cotton wool into articles of use and ornament appears, indeed, to have been carried on in India from the remotest antiquity; but it has not made any very great progress in the East, and obtained no footing worth mentioning in Europe, till last century.

The truth is, that this manufacture, though it now affords employment and subsistence to many hundreds of thousands of persons in this and other countries, is almost wholly a consequence of discoveries and inventions made in Great Britain and the United States, since the middle of last century. Previously to that period the manufacture was everywhere confined within the narrowest limits. Owing to the difficulty of separating the wool from the seed, its price, so long as this operation had to be performed by the hand, was naturally high; while the cost of its spinning and weaving by the wheels and looms in use previously to 1760 added so much to its price, that cotton articles were suited only to the use and demand of the better classes of society; and it seems unreasonable to suppose that the manufacture should have been materially extended without a greatly increased facility of production. But in this respect the most signal and extraordinary improvements have been made. The *Jenny* invented by Hargreaves in 1767 enabled one individual to spin 80 or 120 threads with about the same facility that a single thread had been previously spun. The jenny, however, was fitted only to spin the softer descriptions of yarn or that used as *weft*, being unable to give the thread the firmness and hardness required in that used as *warp*. But this deficiency was soon supplied: the genius of Arkwright completed what Hargreaves had begun, by inventing the spinning frame,—that wonderful piece of machinery which spins any number of threads of any degree of fineness and hardness, leaving to man merely to feed the machine with cotton, and to join the threads when they break! Nearly at the same time that the spinning department was thus wonderfully improved, Dr. Cartwright, a clergyman of Kent, invented the power-loom, a machine which has already gone far to supersede weaving by the hand, and which will, no doubt, in the end bring about this desirable result. While these extraordinary inventions were being made, Watt was perfecting the steam-engine, endowing it with capacity to engrave a seal, to give motion to the most ponderous machinery, or to lift a ship like a bauble in the air; and was thus not only supplying the manufacturers with a new power applicable to every purpose, and easy of controul, but with one that might be placed in the most convenient situations, and amid a population trained to industrious habits.

Still, however, something more was necessary to complete this astonishing career of discovery. Without a vastly increased supply of the raw material at a lower price than it had previously brought, the inventions of Hargreaves, Arkwright, and Watt would have been of comparatively little value. Luckily, however, what they did for the manufacturers, Mr. Eli Whitney did for the cotton growers. This extraordinary person, a native of the southern states of America, invented a machine by which cotton wool is separated from the seed with the utmost facility and expedition. Previously to 1790 the United States did not export a single pound weight of raw cotton. In 1792 they exported the trifling quantity of 138,328 lbs. Whitney's invention came into operation in 1793; and in 1794, 1,601,760 lbs., and in 1795, 5,276,306 lbs. were exported! And so astonishing has been the growth of cotton in the interval, occasioned by this discovery and the discoveries made in England, that in 1838 the exports from the United States amounted to the prodigious quantity of 595,952,297 lbs.!

A cotton mill is, probably, all things considered, the most astonishing triumph of skill and ingenuity. All the various operations, from the carding of the wool to its conversion into a texture as fine almost as that of the gossamer, is performed by machinery. Each of the workmen at present employed in a cotton mill superintends as much work as could have been executed by 200 or 300 workmen 60 or 70 years ago, and yet, instead of being diminished, the numbers employed have increased even in a still greater proportion! It would be curious to investigate how many persons in the old and new worlds directly depend for subsistence on the inventions and discoveries of Hargreaves, Arkwright, Watt, Whitney, and the other founders and improvers of this great manufacture. They certainly amount to several millions; at the same time that there is hardly an individual in any country, how remote or barbarous soever, who is not indebted to them for an increase of comfort and enjoyment.

"It is impossible to estimate the advantage to the bulk of the people, from the wonderful cheapness of cotton goods. The wife of a labouring man may buy, at a retail shop, a neat and good print as low as 4*d*. a yard; so that allowing 7 yards for the dress, the whole material shall only cost 2*s*. 4*d*. Common plain calico may be bought for 2½*d*. a yard; elegant cotton prints for ladies' dresses sell at from 10*d*. to 1*s*. 4*d*. per yard, and printed muslins at from 1*s*. to 4*s*., the higher priced having beautiful patterns, in brilliant and permanent colours. Thus the humblest classes have now the means of as great neatness, and even gaiety of dress, as the middle and upper classes of the last age. A country wake in the 19th century may display as much finery as a drawing room of the 17th; and the peasant's cottage may, at this day, with good management, have as handsome furniture for beds, windows, and tables, as the house of a substantial tradesman 60 years since." (*Baines's Hist. Cotton Manufacture*, p. 358.)

Owing partly to our having had the start in the career of discovery, but more to our command of all but inexhaustible supplies of coal, so indispensable to the cheap and advantageous supply of steam as a moving power, and to the enterprise and invention of our capitalists, engineers, and workmen, we have continued to keep that lead in the manufacture we early acquired. At this moment it affords employment to not fewer than 1,500,000 individuals in this country; and constitutes, in fact, the grand source of our manufacturing prosperity, and the principal element of our commerce.

The following statements give a view of the progress of the manufacture in Great Britain: —

Account of the Imports of Cotton Wool, and of the official Value of the Cotton Goods exported from Great Britain in the following Years, from 1697 to 1764, both inclusive.

Years.	Raw Cotton imported.	Official Value of British Cotton Goods exported.	Years.	Raw Cotton imported.	Official Value of British Cotton Goods exported.
	lbs.	*L.*		*lbs.*	*L.*
1697	1,976,359	5,915	1730	1,545,472	13,524
1701	1,985,868	23,253	1741	1,645,031	20,709
1710	715,008	5,698	1751	2,976,610	45,986
1720	1,972,805	16,200	1764	3,870,392	200,354

The spinning jenny was invented in 1767, and Arkwright took out his first patent for spinning by rollers in 1769. The influence of these and numberless other inventions on the trade is exhibited in the following table: —

Years.	Cotton imported.	Cotton exported.	Years.	Cotton imported.	Cotton exported.
	lbs.	*lbs.*		*lbs.*	*lbs.*
1781	5,198,778	96,788	1810	132,488,935	8,787,109
1785	18,400,384	407,496	1811	91,576,535	1,266,867
1790	31,447,605	844,154	1812	63,025,936	1,440,912
1795	26,401,340	1,193,737	1813	50,966,000	
1800	56,010,732	4,416,610	1814	60,060,239	6,282,437
1805	59,682,406	804,243	1815	99,306,343	6,780,392

The subjoined statement, taken from the circular of Messrs. George Holt and Co., cotton brokers at Liverpool, dated the 31st December, 1840, gives a very complete view of all the more important particulars respecting the British cotton manufacture in the undermentioned years, from 1816 to 1840, both inclusive.

Statement of the Consumption, Exportation, &c. of the different Sorts of Cotton Wool, in and from Great Britain, in different Years, from 1816 to 1840, both inclusive.

Total number of bags consumed	1,236,820	346	426,090,116	23,785
Allowed for loss in spinning, 1¾ oz. per lb.			46,603,606	
Total quantity spun in England and Scotland			-	379,486,510
Deduct quantity spun in Scotland			- -	34,823,466
Total quantity spun in England in 1838			- -	344,663,044
How disposed of.				
Exported in yarn during the year			113,753,197	
Ditto in thread			2,362,983	
Ditto in manufactured goods			120,784,629	
Estimated quantity of yarn sent to Scotland and Ireland			6,875,952	
Exported in mixed manufactures, not stated in the above-named articles, consumed in cotton banding, healds, candle and lamp wick, waddings, flocks, calender bowls, paper, umbrellas, hats, and loss in manufacturing goods			16,753,000	
Balance left for home consumption and stock, 1st January, 1839			84,133,283	344,663,044
Ditto ditto ditto 1838			63,657,902	
Ditto ditto ditto 1837			43,486,686	
Ditto ditto ditto 1836			49,932,800	
Ireland.				
Gross weight of cotton spun in Ireland in 1838			4,412,860	
Allowed for loss in spinning, 1¾ oz. per lb.			482,656	
Total quantity of yarn spun in Ireland in 1838			3,930,204	

In 1832 the quantity spun was 222,596,907 lbs., giving a weekly supply of 4,280,709 lbs. Mr. Burns estimates the quantity spun per spindle, per week, at 8¼ oz., making the total number of spindles employed in England and Wales, in 1832, 7,949,208. Those employed in Scotland, during the same year, are estimated, in the same way, at 381,020. Mr. Burns further calculates the number of looms employed in England and Wales, in 1832, at 203,730. The consumption of flour in the manufacture is much greater than any one not pretty well acquainted with it would readily suppose. The average quantity required for each loom is estimated at 4 lbs. per week; making the total annual consumption in England and Wales, in 1832, 42,301,584 lbs., or 215,824 barrels of 196 lbs. each!

The places whence the supply of raw cotton is derived, and the quantity furnished by each, are seen in the following table: —

Account of the Quantities of Cotton Wool imported into the United Kingdom during the Seven Years ending with 1838; specifying the Quantities brought from different Countries, the Total Quantities exported, and the Quantities left for Consumption. — (Compiled from *Parl. Papers.*)

Manchester, or rather Lancashire, is the grand seat of the English cotton manufacture; and next to it Cheshire, Nottinghamshire, the West Riding of Yorkshire, and Cumberland are its principal seats. Glasgow and the surrounding district is the seat of the manufacture in Scotland. In Ireland it is principally confined to Belfast; but there it is of very limited dimensions, and is said to be rather on the decline.

With the exception of those employed in hand-loom weaving, the condition of the labourers employed in the cotton trade is eminently satisfactory. It has not only made a vast addition to the field of employment, but it has increased the comforts of those engaged in it. The stories once so current as to the cruelties practised upon and the hardships endured by the children and young persons employed in cotton factories were, though not wholly without foundation, grossly exaggerated; — they never, indeed, existed in the first-class mills; and since the system began of excluding children under 9 years of age, limiting the hours of employment, and appointing inspectors, abuses have been wholly put an end to.

The value of the cotton manufacture of Great Britain is greater than that of all Europe besides. And provided tranquillity be maintained at home, and we continue to be exempted from that political agitation that is the bane of industry and the curse of every country in which it prevails, we have nothing to fear from foreign competition. Our natural and acquired advantages for the prosecution of manufactures and trade are vastly superior to those of every other country; and though foreigners do excel us in a few departments, and may come to excel us in others, so that the character and species of

the manufacture may in consequence be partially changed, there is not so much as the shadow of a foundation for supposing that its amount will be at all affected. On the contrary, it is all but certain it will continue to augment with the augmenting wealth and population of the innumerable nations with which we have commercial relations.

It is impossible to frame any accurate estimate of the total value of the cotton goods and yarn annually produced in Great Britain. In the *Commercial Dictionary* they are estimated at about 34,000,000*l.*, and we are inclined to think that this is not far from the mark. Mr. Baines, in his elaborate work on the History of the Cotton Manufacture, gives the following estimate of the number of people employed, and the value of the manufacture.

Estimated Yearly Value of the British Cotton Manufacture.

		£
Wages of		
237,000 *	operatives engaged in spinning and power-loom weaving - -	6,044,000
250,000 †	hand-loom weavers, at 7*s.* per week each - - - - -	4,375,000
45,000	calico printers, at 10*s.* per week each -	1,170,000
159,300 ‡	lace workers (including 100,000 employed in embroidery, and 30,000 in mending, pearling, drawing, and finishing) - - - -	1,000,000
33,000	makers of cotton hosiery - -	505,000
	Bleachers, dyers, calenderers, fustian-cutters, machine-makers; makers of steam-engines, cards, rollers, spindles, shuttles, looms, and reeds; smiths, joiners, builders of all classes, mill-wrights, carriers, carters, warehouse-men, &c. &c.; say - - -	4,000,000
Raw material (spun in 1833) 283,675,200 lbs.¶ at 7*d.* per lb.	- - - -	8,244,693
Profits of capital, sums paid for materials of machinery, coals, flour for dressing, and other outgoings ‖	- - - -	6,000,000
		£ 31,338,693

In the *Commercial Dictionary* the capital employed in the manufacture is estimated at 34,000,000*l.*; which Mr. Baines thinks is very moderate.

COT'TUS. (Gr. *κοττη, a head.*) A genus of spiny-finned fishes; so called on account of the large size of the head. It includes two British species, viz. the Father-lasher (*Cottus bubalis*), and the Sea Scorpion (*Cottus scorpio*); both of which are dreaded by fishermen on account of the painful and dangerous wounds which they inflict by means of the spines with which the gill-covers are armed.

COTYLE'DON. (Gr. *κοτυλη, a hollow.*) In Botany, the seminal leaf of a plant. This organ forms a part of the embryo, and is what nourishes the plumula and radicle at their first period of development, before they are able to subsist upon the organizable matter absorbed by the latter from the earth. Exogenous plants have generally two cotyledons, Endogenous as generally one only; but there are exceptions in both cases. The latter class of plants seldom elevate their cotyledon above ground, and never convert it into a green leaf-like body, but usually leave it behind them within the integuments of the seed; the former frequently raise their cotyledons above the soil in the form of small green leaves, as in the garden radish; but there are very numerous exceptions to this, as in the pea, the oak, the chesnut, &c.

COTYLE'DONS. (Applied by Aristotle to designate the sucking-cups of the arms of the Dibranchiate Cephalopods.) In Comparative Anatomy, the cup-shaped vascular productions of the chorion in Ruminants, serving the office of a placenta, are so called.

COTY'LIFORM. (Gr. *κοτυλη, a cup.*) A term used in describing the general form of organs to denote a rotate figure with an erect limb.

COUCH. A layer or heap of barley, moistened and prepared for malting; also the name of that part of the malting floor on which the barley is spread out.

COUCHANT. (Fr.) In Heraldry, a term applied to a beast when represented as lying on the ground.

COU'CHING. In Agriculture, clearing land from couch grass (*Triticum repens*), which is effected by first pulverizing it, and then, in very dry weather, collecting the couch by harrows, or by a horse rake, such as that used for collecting stubble, and which so applied is called a couch rake.

Cou'ching. One of the operations to restore vision in cases of *cataract:* it consists in depressing the opaque lens, so as to remove it out of the axis of vision.

COUGH. This term is applied to a spasmodic action of the respiratory organs, occasioning a sonorous expulsion of air from the lungs: it is very commonly symptomatic of other affections; and some nosologists have considered that it is always so, and never idiopathic. Many cases of cough depend upon the extension of *catarrh* to the trachea and bronchiæ, which become loaded with mucus or phlegm, the efforts to expel which constitute coughing. Others are perhaps referable to a vitiated secretion; and others to imperfect action of the absorbents, by which the natural mucous secretion remains and accumulates in the air vessels, and by evaporation becomes inspissated and irritating; this appears to be one of the causes of the dry cough to which old people are subject. The treatment of catarrhal cough consists in allaying irritation by demulcents, such as mucilaginous drinks and lozenges, which, acting upon the glottis, sympathetically affect the trachea and its ramifications: amongst these extract of liquorice, and lozenges made of it and equal parts of gum tragacanth, are very effectual. Stimulants and full diet are to be avoided, and inflammatory symptoms carefully guarded against; for these are not unfrequently brought on by the violence of a cough. It is not unfrequently necessary to call in the aid of sedatives, expectorants, and aperients. Amongst the former small doses of Dover's powder, or of equal parts of it and extract of henbane, are very serviceable; and it is not uncommon to observe a troublesome cough disappear after a brisk dose of physic. An emetic will also sometimes effect its cure; so that coughs have been by some considered as symptomatic of a vitiated state of stomach and bowels. Where a cough periodically returns at night, and is not inflammatory, a dose of laudanum sufficient to induce sound sleep will often, as it were, break the habit and relieve it. Sedatives, conjoined with stimulating expectorants, such as squills, ammoniacum, benzoic acid, &c., are often effectual in relieving the coughs of old age; and in these, and what are called nervous coughs, much relief is experienced by administering mild opiates in the form of lozenges, so that they may pass gradually over the neighbourhood of the affected part, in consequence of the slowness with which they are dissolved in the mouth and swallowed: lozenges of sugar, liquorice, or tragacanth, with about two grains of extract of poppies in each, are useful in such cases. Where coughs are symptomatic of inflammatory action, of asthma, &c., they often require modes of treatment which have more particular reference to their exciting causes.

COU'LTER. (Lat. culter, *the coulter of a plough.*) In Agriculture, an iron blade or knife inserted into the beam of a plough, for the purpose of cutting the ground and facilitating the separation of the furrow-slice by the ploughshare. *See* Plough.

COU'MARIN. A crystalline odoriferous principle extracted from the tonka bean, which is the seed of the *Coumarouna odorata.*

COU'NCIL. In Church History, an assembly of prelates and other spiritual persons for the regulation of ecclesiastical matters. Such councils are either national, or œcumenical; the latter being those in which the whole body of the clergy throughout the world is represented, and are convened for the settling of points of universal interest.

The Roman Catholics hold that the decision of œcumenic or general councils are infallible, and for the most part allow their superiority to the popes themselves. This superiority was first asserted at the Council of Pisa, in which the two reigning anti-popes were deposed; and confirmed by the proceedings of those of Constance and Basil. Since that time the popes have been very unwilling to convene a general council, and that of Trent is the only one that has assembled in later times.

The Protestants allow the authority of general councils in matters which do not contradict Scripture, and attach great importance to the four first councils; viz. of Nice, Constantinople I., Ephesus, and Chalcedon. But they maintain that a general council can only be called by a

* Mr. Stanway, from the Returns of the mill-owners, ascertained that 67,819 mill operatives in England received 141,635*l.* 5*s.* 7¾*d.* as wages for a month of four weeks: at the same rate, 237,000 mill operatives, the number in the United Kingdom, would earn 6,434,453*l.* per year. But, as wages in Scotland are 10 per cent. and in Ireland 15 or 20 per cent. lower than in England, and as two weeks' wages in the year ought to be deducted for holidays, the amount of wages paid will be about 6,041,000*l.*

† In my estimate of the *number* of weavers I have not reckoned the winders, draw-boys, &c. who assist them, and who must amount to a great many thousands; but, in the supposed average of their *wages*, I include those earned by the assistants of the weavers as well as by the weavers themselves. The sum of 7*s.* per week for the *gross* wages of all the hand-loom weavers is, I am convinced, a fair estimate. The calculation is for 50 weeks in the year.

‡ The wages paid to the women and children employed in embroidery, mending, &c. the lace, must be extremely low. Mr. Felkin estimates the whole value of the lace manufactured in England at 1,850,650*l.*; deduct the cost of the yarn, 635,000*l.*, and there remains the sum of 1,215,650*l.*; of which, probably, 1,000,000*l.* consists of wages to the work-people.

¶ The quantity stated by Burns in the *Commercial Glance.*

‖ "I adopt this sum from Mr. M'Culloch, thinking it a moderate estimate."

temporal prince, which prerogative is assigned by the Romanists to the pope.

Their infallibility they strongly deny, and appear to reduce that assumption to an absurdity by asking —

1. What is the proof of infallibility existing in the church at all?

2. Supposing it to exist, how can it be shown that the church has been truly represented in any council? Or,

3. How can it be shown that the infallibility resides in a bare majority rather than the minority, when a difference of opinion prevails?

COU'NCIL, PRI'VY. The principal council belonging to the king of England. In its origin it appears as a small permanent committee, or minor council, consisting of members selected by the king himself out of the great council of the kingdom. The latter body is supposed to have been originally composed of all the immediate tenants of the crown; and it was occasionally summoned as late as the reign of Ric. II., and seems then to have comprised nearly all the prelates, nobles, and bannerets of the kingdom, "*et autres sages.*" When the privy council was formed out of it has not been ascertained. It appears in early rolls of parliament as the permanent or continual council; and as its powers under the Plantagenet kings were very extensive, so parliament exercised considerable influence in controlling the appointment of its members, although always vested in the crown as an essential prerogative. The privy council under these sovereigns usually consisted of the five great officers of state, the two archbishops, and from ten to fifteen other individuals, spiritual or temporal. It sat continually as a court, both to expedite the executive part of the administration, and to provide equitable relief in cases submitted to it, thus controlling the courts of common law. (See *Sir F. Palgrave's Essay on the Original Authority of the King's Council*, 1834; and the Preface to the *Records of the P. C.*, edited by Sir H. Nicolas.) There were also under the Tudors councils, portions of the privy council, exercising like powers in various parts of England. The increasing power of parliament on the one hand, and the extended equitable jurisdiction of the lord chancellor on the other, gradually encroached upon the ancient dignity and importance of both the councils. The decline in power of the privy council was, however, extremely gradual. The Star Chamber and Court of Requests, dissolved in the reign of Charles I., were both committees of the privy council. By stat. 16 C. 1. its direct jurisdiction in England in civil cases was taken away.

Privy councillors are made by the king's nomination, without patent or grant. Their number, having greatly increased under the Tudor princes, was restricted by Charles II. to thirty; but soon became indefinite again, and has so continued. But no privy councillors attend except such as are specially summoned. The privy council continues in office six months after the demise of the crown, unless sooner dissolved by the successor. The separation of the functions of the privy council from the more important political duties of the cabinet council seems to have been chiefly effected in the reign of W. III.

The jurisdiction of the privy council is of several sorts: 1. The king in council may issue proclamations binding on the subject, if consonant to the laws of the land. He issues also orders in council for the temporary regulation of various matters relating to trade and international intercourse. 2. The privy council has power to inquire into offences against government, and commit offenders to take their trial according to law. 3. Appellate jurisdiction in the last resort from all his Majesty's dominions, except Great Britain and Ireland, is vested in the privy council. By 3 & 4 W. 4. c. 41. a judicial committee of the privy council is constituted, to which are entrusted appeals from the prize and admiralty courts, and courts in the plantations abroad, and all other appeals which might before have come before the king in council. The judicial committee may direct feigned issues to be tried at common law. The lord president of the council is the fourth great officer of state. The office must probably have been cotemporaneous with the origin of the council itself; but the title is comparatively recent. It was created by Hen. VIII., and revived by Charles II. in favour of the Earl of Shaftesbury.

COU'NCIL OF STATE. A political and judicial body of very indefinite powers in the French monarchy, both before and since the Revolution.

COU'NSELLOR. (Lat. consiliarius.) In Law, a person retained by a client to plead his cause, who is also said to be of counsel for him. For the regulations by which the admission to practise as a counsellor is restricted in England, see BARRISTER.

COUNT. (Lat. comes, *a companion*; or according to a fanciful conjecture of some etymologists, from comedere, *to eat with*, because the holders of this dignity had the privilege of dining with the emperor.) A title of dignity in most of the continental states of Europe, equivalent in rank to the British earl and the German *graf*. This title has been in existence since the time of Augustus, who is said by Dion Cassius to have thus designated all the officers of his household. Under the Lower Empire and the first two races of the Frank kings, this title of count was given to officers of various degrees, and was at first attached to the office, and not to the person; but in the progress of time, when feudalism had introduced inheritance instead of election as a fixed rule in succession, it became subject to the same law as the higher titles of kings and dukes, and conferred hereditary privileges on its possessor. (*See* FEUDALISM.) The term count has in most of the states where it is in use degenerated into a mere title, to which no political importance is attached. "In the Papal states it may be bought for no considerable sum, and in most of the German states the sovereign may confer it as a mark of honour or esteem." Though the title count has never been introduced into Britain, the wives of earls have from the earliest period of its history been designated as *countesses*. (For further information on this subject, see *Dutillet's Recueil des Rois de France*.)

COUNT. In Law. *See* DECLARATION.

COU'NTERFORT. (Fr. contre, *against*, and fort, *strong*.) In Architecture, a buttress or pier built against and at right angles to a wall to strengthen it.

COU'NTERGUARDS, in Fortification, are small ramparts with parapets and ditches, to cover some part of the body of a place. They are generally made before the bastions, sometimes before the ravelins.

COU'NTERMARK. In Numismatics, a stamp frequently seen on ancient coins, often obliterating a large part of the impression. The countermark is generally a figure or inscription; and some antiquaries have considered that their use was to augment the value of the money; others, that it was only struck on money taken from an enemy.

COU'NTERPART. In Law, when the parts of an indenture are interchangeably executed by the several parties, that part which is executed by the grantor is termed the original, and the rest are counterparts. If each part is signed by all parties, they are duplicate originals.

COU'NTERPOINT. (It. contrapunto.) In Music, a composition of several parts. The name originated in the circumstance of the notes being formerly placed one against or over the other, and without any stems.

COU'NTERPROOF. In Engraving, an impression obtained from another impression while it is yet wet from a copper plate, in which the design is in the same direction as in the plate itself. They are made chiefly for investigating the state of a plate; and of some prints the counterproofs are more valuable than the prints, where the drawing from the picture has not been reversed on the copper.

COU'NTERSCARP. In Fortification, the slope or *talus* of the exterior side of the ditch, towards the country. The interior slope is called *escarpe*. Sometimes the whole covert way, with its parapet and glacis, are termed *counterscarp*.

COU'NTERSIGN. In Diplomatics, the signature of a public officer to the charter of a king, prelate, &c. by way of certificate. "Obtulit," "recognovit," "relegit et subscripsit," are common additions, in charters of the middle ages, to the name of the countersigner.

COU'NTER-TE'NOR. In Music. *See* TENOR.

COU'NTY. A county is in England that district of territory which was anciently subject to the government of an earl or ealdorman, from whose Latin title *comes* the term is derived. The Saxon word corresponding to county was shire, meaning division, which is therefore not applied to such counties as were originally distinct sovereignties; such as Kent, Essex, Sussex, Middlesex, Suffolk, Norfolk.

The division of the kingdom into counties, which, in common with many other of our earlier institutions, is commonly attributed to Alfred, though it was probably of a date far anterior, was in ancient times chiefly of use in marking the limits of different jurisdictions. To each county belonged a county court, which it was the duty of the thanes and other freeholders to attend and do suits at, though it seems the thanes only took part in the administration of justice. Such court was originally held by the earl and bishop, the latter assisting in respect of the ecclesiastical jurisdiction belonging to the court; or in their absence by the sheriff, upon whom the right to preside in the county court, either in person or by deputy, as well as the other civil functions of the earl, have long since devolved. Considered in its judicial character, the county court was the great court baron or civil court of the county, and was originally competent to the trial of almost all civil actions arising within such county. The criminal jurisdiction belonging to the county, which is now vested in the magistrates at quarter sessions, was anciently exercised by the sheriff in his tourn (*see* title TOURN). The boundaries of a county serve also to mark the limits of the jurisdiction, both civil and criminal, which other courts or judges exercise within each county severally by commission from the crown (*see* VENUE); and within which limits also are

confined the ministerial functions of the sheriff as executor of the writs awarded by either of the great courts.

The division into counties is also for some purposes, particularly that of representation in parliament, political; and it is in the county court that the election of members of parliament takes place, and that other political acts of the men of the county are done; for county meetings convened and presided over by the sheriff are, properly speaking, holdings of the county court. What has been said of counties in England applies without qualification, save as to the time of the institution; to Wales, and, with very little qualification, to Ireland and Scotland; the most important point of difference being the greater extent of the jurisdiction and power of the sheriff in the latter country. There are in England 40 counties, in Wales 12, in Scotland 32, and in Ireland 32.

A County Palatine, of which description there are now two in England, viz. Durham and Lancaster, is a county in which all jura regalia, *i. e.* the whole rights of sovereignty in judicial matters, belonged to the earl of such county; but these privileges are now reduced to the possession of courts of their own, corresponding in number and jurisdiction to the King's courts at Westminster, whose jurisdiction is not excluded by theirs, and whose writs may be so framed as to run within the limits of the county palatine.

COU'NTY COURT. The County Court properly so called is a court baron, not of record, for civil causes, held by the sheriff in each county. This court can only hold pleas where the debt or damage is under 40*s*., except by virtue of the writ called of *justicies*, which is a special precept to the sheriff to do justice between parties in the same manner as it might be done in the courts of Westminster. Causes are removed out of this into the higher courts by writ of recordari. (For the extension of the powers of the sheriff by statute to try personal actions of greater amount, see SHERIFF; *Read's County Courts; Greenwood on Courts; Watson's Sheriffs.*)

COUNTY RATE. *See* RATE.

COU'PLED COLUMNS. In Architecture, columns half a diameter apart. *See* ARÆOSYSTYLOS.

COU'PLING BOX. A strong iron cylinder, by which the shafts of machinery are connected.

COURIERS. (Fr. courir, *to run.*) A name given in ordinary language to the bearers of public despatches or private intelligence by express. The institution of persons to convey intelligence with celerity and regularity is coeval with the earliest history of civilized nations. By the Persians they were styled *αγγαροι*, by the Greeks *ἡμεροδρομοι*, and by the Romans *cursores;* and the duties of the ancient couriers seem to have been wholly analogous to those of the moderns, and were performed chiefly on horseback; though the original derivation of the name would lead to an opposite supposition. In the middle ages couriers were known by the appellation trottarii, or *trotters;* and hence perhaps originated the English term *running footmen*, of whom history makes mention in the 17th and 18th centuries.

COURSE. (Lat. cursus.) In Architecture, a continued level range of stones or bricks of the same height throughout the face or faces of a building. *See* BOND.

COURSE OF CROPS. The rotation or succession in which crops follow one another, in a prescribed course of cropping. The rule is to follow a crop grown for its seeds or roots by one grown for its leaves or stems.

COU'RSERS, *Cursores*. (Lat. curro, *I run.*) An order of birds, including those which are disabled from flight by the restricted development of the wings, but which possess superior powers of running from the compensating size and strength of the legs: the ostrich, rhea, casowary, emeu, and apteryx are examples of this order.

COU'RSES. The lower square sails, as the foresail and mainsail.

COU'RTESY. (Fr. courtoisie, Ital. cortesia.) It was at the courts of princes and great feudatories that the minstrels and troubadours of the middle ages especially delighted to exercise their art; and it was there, also, that the peculiarities of chivalrous life and manners were chiefly exhibited. Hence courtesy was a general term, expressive of all the elegance and refinement which the society of those times had attained; in fact, it was synonymous with all the gentler parts of chivalry itself: and it is in this sense that it is used both by the early trouvères and romancers, and also by poets of a later age, when affecting the use of chivalrous language, as in the first lines of the great poem of Ariosto:—

> Le donne, i cavalier, l' arme, gli amori,
> Le *cortesie*, l' audaci imprese io canto.

The transition from this wider meaning to that in which it is now employed is obvious enough. It may be sufficient to refer to the very ingenious theories of Signor Rossetti respecting the secret meaning attached to this (among other) words of frequent occurrence in the poems of the Italian canzonieri of the thirteenth and fourteenth centuries. (*Inferno di Dante*, 1827, vol. ii. p. 430, &c.)

COURT PLASTER. Black silk varnished over with a solution of isinglass, which is often perfumed with benzoin.

COURTS OF JUSTICE, are divided by the rules of English law into courts *of record* and *not of record.* The former have power to make up their acts and judicial proceedings in the form technically called a *record*, as evidence of their judgment. All courts having power to fine or imprison are said to be impliedly courts of record; but this seems questionable.

The courts termed Superior are divided into those of Law, Equity, Ecclesiastical, Maritime, Prize or International, and Courts of Appeal and Error. They are,—

Three Superior Courts of Common Law (*see* COURTS, SUPERIOR), being—

1. The Court of King's Bench. *See* KING'S BENCH.
2. The Court of Common Pleas. *See* COMMON PLEAS.
3. The Court of Exchequer. *See* EXCHEQUER.

Four Superior Courts of Equity (*see* CHANCERY), being—

4. The High Court of Chancery.
5. The Rolls Court.
6. The Vice-Chancellor's Court.
7. The Equity side of the Court of Exchequer.
8. The Ecclesiastical Courts. *See* ECCLESIASTICAL COURTS.
9. The Court of Admiralty. *See* ADMIRALTY.
10. The Prize Court. *See* ADMIRALTY.
11. The Courts of Bankruptcy. *See* BANKRUPTCY.

The Courts of Error and Appeal are—

12. The Exchequer Chamber, from the Superior Common Law Courts. *See* EXCHEQUER CHAMBER.
13. The Privy Council, and Judicial Committee of the Privy Council, which are Courts of Appeal from the Ecclesiastical Courts, Admiralty, and also from the decisions of various Colonial Judicatures.
14. The High Court of Parliament. *See* PARLIAMENT.

Inferior Courts are numerous, both of record and not of record; being for the most part local jurisdictions of very various extent and authority. To these belong the Courts of Conscience and Requests, Courts Baron, Hundred Courts, Borough Courts, and County Courts, in which the sheriff presides.

COURTS, SUPERIOR. The three superior common law courts of England are the Court of King's Bench, of Common Pleas, and of the Exchequer. For the origin and history of each court, and its peculiar jurisdiction, see those separate heads.

For several centuries, by means of various admitted fictions, these three courts have exercised a concurrent jurisdiction in all personal actions (*see* ACTIONS); and the practice of all three is, in material points, the same. They sit, during term, at Westminster. The different branches of jurisdiction of the three superior courts are, 1. That of the full court in *banc*, during term only, when four judges sit together in each; 2. Of the Practice or Bail Court (created by the 1 W. 4. c. 70. s. 1., which as yet has been brought into operation in the King's Bench only, in which a single judge disposes of some less important matters of business); 3. Of a single judge at chambers, where also points of minor importance in the conduct of a cause are decided and directions given; 4. Of the master or prothonotaries, officers to whom various matters of fact, as computations, &c., are referred; 5. Of the judge at Nisi Prius and on the circuit, for the trial of issues in fact; 6. Of the sheriff in each county, who may be considered as an officer of the superior courts for the purpose of trying issues directed to him under 3 & 4 W. 4. c. 42.

The course of proceeding in the superior courts is either formal or summary. Formal proceeding, in personal actions, is the regular course of a trial, whether the issue, or question tried, be one of fact or law. The party complaining, or plaintiff, having brought the defendant into court in person, or constructively, by preliminary *process*, entitles his *declaration*, or the form of statement of his grievance (*see* PLEADING), as of one of the three courts, the same in which the writ for commencement of the action is said to be *returnable*. The defendant then pleads; and all the subsequent pleadings, or preparatory statements in writing, are entitled of the same court: in which also the record, or parchment roll containing the authentic entry of the whole proceeding, is made up. The question eventually raised between the parties will turn out to be either of law, or of fact. The former, being raised on what is termed a *demurrer* (*see* PLEADING), is argued at Westminster before the full court, and the judgment in law is conclusive of the issue. If the question be of fact, it must be tried by a jury. If the pleadings are dated at London or in Middlesex, as in *local* actions they must be if the question arise in those districts, and as in *transitory* actions they

may be in all cases (*see* PLEADING), the jury will be summoned accordingly, and the case tried before a judge of the court in which the action is brought, at *nisi prius* (see that head), either during term or in the sittings after term. If, on the other hand, the date, or *venue*, as it is termed, be in any other county, the parties proceed to trial at the assizes (the plaintiff bringing down the record from Westminster, by which means it is in his option to proceed to trial or not). In this case a jury is summoned in like manner before the judges of assize, by virtue of their commission of oyer and terminer. In some special cases, trial at bar is granted on application; in which case the cause is tried by a jury before the full court, at such time as the court may fix for convenience. If a party imagines himself to have grounds for being dissatisfied with the result of a trial, as, that the judge has summed up the evidence improperly to the jury, or that material testimony has been illegally rejected, he may move the court at Westminster for a new trial, or to set aside the verdict, according to the circumstances of the case; and such motion is made before the full court in term. On the issue of the trial judgment is awarded, declaring that the plaintiff either has, or has not, entitled himself to the remedy prayed; and costs are given with the judgment; after which the successful party may sue out execution, unless there be an appeal by writ of error, which only lies on matter of law arising on the face of the proceedings.

Summary proceedings are of very miscellaneous character; and are by affidavit, motion, rule *nisi* (*i. e.* unless cause is shown against the rule on a certain day; when, if no cause, or insufficient cause, is shown, the rule is made absolute; and if made absolute, followed by demand of performance, and this performance enforced by means of attachment for contempt of court). By these means the courts have extensive authority to give directions and enforce conditions during the progress of a suit. Among summary proceedings may also be enumerated the leave given, on motion, to amend various formal defects in pleadings.

COURT BARON. A Court Baron, so called either from the lord or baron who presided over it, or from the freemen, in ancient times also called barons, who were its suitors and judges, was a court, having its origin apparently in notions of a patriarchal jurisdiction, properly and in the first instance incident to every manor, in which it was held by the lord of the manor or his steward, who, assisted by the freeholders of the manor, there decided on the purely civil controversies which arose between them. A court baron also belonged to every hundred and county (see those titles); and in many cases also to particular franchises or lordships, which might include several manors. Courts baron, from the inferiority of their judges, and from the defects of their jurisdiction, which a party might defeat by removal of the cause to a higher tribunal, have long fallen into disuse; except in manors of ancient demesne, where the jurisdiction was, and in some respect still is, in the first instance exclusive, the lord of such manors having once been the king; and except in manors containing land of copyhold or customary tenure. *See* COPYHOLD.

COURT-MARTIAL. A court for trying and punishing the military offences of officers and soldiers. Courts-martial, in our law, are bound by the same rules and principles of evidence as courts of law. Their jurisdiction is conferred by the Mutiny Act (1 W. & M.), which is annually renewed. The crimes cognizable by them are designated by the Mutiny Act and Articles of War. The persons liable to martial law are officers, soldiers, and persons serving with the army in the field; and receiving pay as a soldier subjects the receiver to it; but officers on half-pay are not liable. The judgments of courts-martial are open to the disapprobation of the king or his commanders-in-chief; and are likewise liable to reversal by the Court of King's Bench. The acts of a court-martial, like those of other courts instituted by statute with particular powers, may become the subject of application to the courts at Westminster for a prohibition. *Naval courts-martial* have their jurisdiction defined by the thirty-six articles of war, embodied in 22 G. 2. c. 23. and 19 G. 3. c. 17., and are composed of admirals, captains, and commanders. (See *M'Arthur on Courts Martial; Kennedy on C. M.; James, Collection of Proceedings of C. M.* 1820; *Tytler on Military Law.*)

COU'SSINET. (Fr. *a cushion.*) In Architecture, the crowning stone of a pier, or that which lies on the capital of the impost and under the sweep. Its bed is level below and inclined above, receiving the first rise or spring of the arch or vault. This word is also used for the ornament in the Ionic capital, between the abacus and echinus or quarter round, which serves to form the volute, and is thus called because its appearance is that of a cushion or pillow seemingly collapsed by the weight over it, and bound with a strap or girdle called the baltheus.

COVE. An inlet on a rocky coast. It is a term nearly synonymous with *harbour;* the word cove being generally, though not always, used when the indentation on the coast is too shallow or narrow to admit first-class vessels.

CO'VENANT. In History, the famous bond of association adopted by the Scottish Presbyterians in 1638. It was framed on the model of a similar declaration, which had been twice solemnly subscribed in the early period of the Reformation: but in more violent language, and with more specific obligation to support the kirk, together with a prohibition and abjuration of the Anglican liturgy and articles. The founders of the Solemn League and Covenant were Alexander Henderson, leader of the clergy, and Archibald Johnston of Wariston, an advocate. (See *Laing's History of Scotland*, vol. iii.) A new religious covenant between the two kingdoms was framed in 1643, and taken by the English House of Commons and assembly of divines at Westminster. Charles II. subscribed the Scottish covenant on his coronation in 1651; but on his restoration it was declared null by act of parliament, and burned by the common hangman. It formed, however, the watch-word and bond of union of the discontented party, or Covenanters, as they were called, in the rebellions of his reign.

COVENANT. In a theological sense, a promise made by God to man upon certain conditions: the two grand distinctions of which are emphatically designated the Old and New Covenant or Testament; in each of which certain temporal or spiritual benefits are promised to man upon the performance of duties therein pointed out.

COVENANT. In Law, is an engagement under seal to do or to omit a direct act. Covenants are of many different species, as, in fact and in law, implied and express, &c.; and, according to their subject matter, or express stipulation, they are binding respectively on the heirs, executors, and assigns, or executors and assigns only, of the covenantor.

COVENANT is also a form of action, which lies where a party claims damages for breach of a covenant or contract under seal.

COVENA'NTERS. The great body of the Scottish people, at the era of the Reformation, adopted the presbyterian faith and polity as established by Calvin at Geneva, and as introduced into Scotland by Knox, and recommended and enforced by his eloquence. As presbyterianism was thus closely associated in their minds with their deliverance from what they regarded as the degrading authority of popery, the people of Scotland have ever been distinguished for their cordial and unflinching adherence to this new faith. But though it was the object of public veneration, it never succeeded in gaining permanently either the affection or countenance of the court. On the contrary, the successive monarchs by whom Scotland was governed from the Reformation in 1560 till the final establishment of presbytery as the national church in 1690, regarded it with disfavour, and did all in their power, either by open persecution, or by private intrigue, to undermine and destroy it. They regarded it, being a republican hierarchy, as incompatible with royal authority; and James VI. declared that "presbytery and monarchy could no more agree than God and the devil." But though, owing to royal favour, episcopacy, or "black prelacy," as it was contemptuously called by the presbyterians, occasionally predominated, it was as often superseded by presbytery. The latter, after having been for some time displaced by prelacy, gained the superiority in 1592; from which time till 1606 it was established as the national religion. At this latter period, however, episcopacy obtained the mastery, which it enjoyed for upwards of thirty years. But though this polity, being favoured by the influence of the court, so long maintained the ascendency, it continued as obnoxious as ever to the great body of the Scottish people. Indeed, so obnoxious was it known to be, that, though episcopacy legally prevailed, it was thought prudent for some time nominally and formally to rule the church by means of the ecclesiastical judicatories peculiar to presbytery. But the people were not so easily deceived; nor could any consideration induce them either to forego the ecclesiastical polity which was so dear to them, or look on its rival with the least degree of toleration or favour. Matters at length came to a crisis on this subject. Charles I. having introduced that arbitrary judicatory in matters religious and ecclesiastical, the High Commission Court, and having attempted to introduce the Book of Canons and the Liturgy or Service Book, the public voice was aroused, and public indignation was generally and unequivocally expressed, particularly in Edinburgh, where a very serious tumult took place (July, 1637) on a Sunday, on occasion of an attempt being made (according to royal proclamation) to read the liturgy in the church of St. Giles. Supplications against the liturgy issued from almost every quarter of the country, from all classes of the people, and from the great majority of municipal corporations, and were carried by the principal men of the kingdom to be presented to the privy council. These supplications were not attended with the success which it was hoped they would have experienced. But the

supplicants or the public were not to be driven from their purpose. The supplicants, who had flocked to Edinburgh in great numbers, could not long remain there. But the most effectual means were adopted to keep up an organized opposition to the royal procedure in this matter. Four *tables*, as they were called, were formed. One table consisted of nobility, another of gentry, a third of clergymen, a fourth of burgesses; thus representing all ranks and classes of the people. There was also a general table, composed of representatives from the four subordinate tables, which received suggestions from these, and decided on what steps it was necessary to adopt. One of the first acts they passed was the production of the *Covenant;* and hence all those who either then or afterwards subscribed it or gave in their adherence to it, were denominated *Covenanters.* (*Baillie's Letters*, i. *passim; Laing's Hist. of Scotland*, iii.; *Cook's Hist. of the Church*, iii.; *Acts of General Assembly.*)

The origin of the Covenant in Scotland may be traced to the Reformation, during the progress of which it was renewed several times; and it evidently had a reference to the covenants so frequently adopted by the children of Israel, and by which they bound themselves to adhere to that religion which the Almighty had established among them.

The Covenant to which we at present more immediately refer, is in many respects a renewal of the Covenant which was subscribed in the year 1580, 1581, and 1590, but so modified and enlarged as to embrace the circumstances under which the church was placed at the interesting crisis under review. It inveighed not merely against popery, as the former Covenant had done, but "against the danger of the true reformed religion (that is, the presbyterian faith and polity as established in 1592), of the king's honour, and of the public peace of the kingdom, by the manifold innovations and evils" so generally prevalent. The subscribers also profess, and "before God, his angels, and the world, solemnly declare, that, with their whole heart, they agree and resolve all the days of their life constantly to adhere unto and to defend the foresaid true religion." "We promise and swear," to use their own words, "by the great name of the Lord our God, to continue in the profession and obedience of the foresaid religion; and that we shall defend the same, and resist all these contrary errors and corruptions, according to our vocation, and to the uttermost of that power that God hath put in our hands, all the days of our life." (*Vide* the *National Covenant* appended to the *Westminster Confession of Faith*, p. 483. edit. 1815.)

These expressions, however unequivocal or strong, are not more energetic than others in the same document. They showed that the persons by whom they were uttered were in earnest, and that nothing could satisfy them but the abolition of the High Commission Court, and the revocation of the canons and liturgy; in other words, the total and unconditional abrogation of prelacy. They insisted on the questions that existed between them and the king being immediately submitted to a free General Assembly of the Kirk, and to parliament.

Meanwhile the tables invited all the supplicants to repair from the country to attend a solemn meeting, which was to be held in Edinburgh in honour of the Covenant The supplicants having obeyed the summons, the Covenant (1st March, 1638) was solemnly subscribed and sworn, amid prayers and with uplifted hands, by the nobility, gentry, clergy, and burgesses; by thousands of all classes, of both sexes, and of every age. Nor was this all. Commissioners were immediately despatched with copies of it throughout Scotland; and in a few weeks every district of the country, with some partial exceptions, submitted to the Covenant.*

The nation was now divided into two parties,—the *Covenanters*, a name originally imposed by their adversaries, and the *Non-Covenanters;* the latter being a small, feeble, and scattered body. (*Baillie's Letters; Livingstone's MS. Life.*)

Charles, seeing the formidable position assumed by the Covenanters, and the influence which they possessed, was at length willing to recal the liturgy and the canons, and to make considerable concessions for the sake of peace. But it was too late: no compromise could now be accepted; nothing would satisfy the Covenanters but the extirpation of prelacy: nothing that fell short of this would be at all listened to. Nay, so far did they carry their condemnation of the bishops, that they had not only preferred an accusation against them as the authors of the innovations, but had, meanwhile, applied for an interdict, prohibiting them from having a seat in the privy council. The prelates, indeed, finding that they were the object of public odium, and that their influence was nearly gone, voluntarily withdrew from the council. The king, after much temporizing and intrigue, found himself obliged, however reluctantly, to agree to the meeting of the General Assembly on the terms which the Covenanters had proposed,—namely, that lay-elders should, as in the best days of presbytery, be recognized as constituent members of the inferior ecclesiastical courts, and eligible as members of assembly; that not only should the bishops, the former official moderators (presidents) of presbyteries, not be replaced, but that these dignitaries might be legally prosecuted by the Assembly, and their usurpations restrained, if not their order entirely suppressed. (*Ib.*)

The Assembly accordingly met at Glasgow in November, and continued its sittings (for thirty days) as its inalienable right, even though the royal commissioner, the Marquis of Hamilton, had meanwhile declared the meetings dissolved. It embraced in the list of its members the most eminent of the nobility and gentry as lay-elders. It not only annulled the canons, liturgy, the High Commission Court, and other innovations, but it abolished episcopacy itself, and declared it as having been from the first both illegal and unscriptural. Of the prelates, fourteen in number, of whom the Scottish hierarchy had consisted, eight were excommunicated, four deposed, and the remaining two merely suspended from their ecclesiastical functions. Nor did the Assembly stop here; for, while it abolished prelacy, it re-established presbytery as it had existed previously to the late innovations, with all the privileges, liberties, powers, and jurisdictions which it had formerly enjoyed. (*Acts of Assembly*, 1638.)

The proceedings of this Assembly, particularly its contemptuous and summary mode of dealing with the favourite hierarchy of the king, could not be agreeable to Charles. These proceedings were, on the contrary, so obnoxious to him that, on the Supplication voted at the conclusion of its meetings being presented to him, he expressed himself as deeply offended, and declined to return any answer to it. "When the Covenanters," says he, "have broken my head, they will put on my cowl." This injudicious conduct on the part of the king brought matters to a crisis. Both parties prepared for war; a step, however, which the Covenanters, who always professed the greatest loyalty, adopted with reluctance. So devoted, however, were the people to what they regarded as a righteous cause, that the expense on the side of the Covenanters, who included in the list of their adherents almost every individual in Scotland, was defrayed by a general voluntary assessment. In raising both men and money the clergy took an active part; and contributions for carrying on the war were levied by them from their respective flocks to an extent scarcely credible. "We sent from Stranraer," says John Livingstone, then minister of that parish, "our fourth fencible man, viz. 15 men. The town was but little and poor; all the yearly rent was estimated at 2000 merks Scots * * *. I propounded to my flock the condition of the army, and desired they would prepare their contribution to be given after sermon; at which time we got 45*l.* sterling," or nearly the half of the whole income of the place. (*MS. Life*, p. 34.) Nor was the spirit which pervaded the army less interesting or enthusiastic than that which characterized the whole body of the Covenanters. "Every company," says an eyewitness, "had fleeing at the captain's tent door a brave new colour, stamped with the Scottish arms, and the motto, *For Christ's Crown and Covenant*, in golden letters." (*Baillie*, i. 174.) Every regiment was attended by a chaplain. "I carried myself," says Dr. Baillie, who attended the army in the capacity of a chaplain, "as the custom was, a sword and a couple of Dutch pistols at my saddle." "Our soldiers grew in experience of arms, in courage, and favour daily. Every one encouraged another: the sight of the nobles and their beloved pastors daily raised their hearts. The good sermons and prayers, morning and evening, under the roof of heaven, to which their drums did call them for bells, the remonstrances very frequent of the goodness of their cause, of their conduct hitherto by a divine hand, made them as resolute for battle as could be wished." "Had you lent your ear, in the morning, or especially at even, and heard in the tents the sound of some singing psalms, some praying, and some reading scripture, ye would have been refreshed." (*Ib.*)

Such was the spirit under the influence of which the Covenanters waged and carried on the war with their sovereign. Of the hostilities that ensued it is unnecessary here to give a farther account than to say, that the Covenanters, though they gained the only battle that was fought, lost no time in making proposals of peace. These proposals were accepted by the king; and a treaty was concluded (June, 1639) four months after the commencement of the war. Of this treaty the most important clause was,

* So pertinaciously was subscription of the Covenant insisted on, that no student could enter college, or take a degree there, and no person could be admitted to the Lord's Supper, without having first subscribed this obligation. Not only were such persons as professors and teachers, but every human being of whatever rank, bound to subscribe under the risk of "all ecclesiastical censure." Those "suspected of papistry" were summoned before the church courts, with a view of inducing them to sign the Covenant; and if they refused, they were ordered to be proceeded against and tried as disaffected persons. Every university, synod, presbytery, and parish were obliged to have each a copy of the Covenant in 4to., "with some blank paper, whereupon every body may be obliged to sign." Subscription of the *Solemn League and Covenant*, afterwards to be spoken of, was prosecuted with almost equal zeal. (*Acts of Assembly, apud annos* 1639-48.)

that, as the king would not ratify the enactments of the Assembly of Glasgow, and as the Covenanters would not annul them, a free General Assembly should be held in the ensuing month of August, and a parliament immediately afterwards; to the decision of which courts every dispute between the contending parties was to be referred. This Assembly met accordingly; and its proceedings, as might have been expected, were exactly of the same character as those of the former: and yet, such was the progress of public opinion, that the Earl of Traquair, the royal commissioner, not only did not refuse to ratify them, but consented to subscribe that obnoxious bond, the Covenant, which was ordained, under the penalty of ecclesiastical censure, to be subscribed by all ranks. The members of the privy council, besides, gave to the Covenant the sanction of their authority, and attached their signatures to it. (Ib.)

The proceedings of this Assembly were, if possible, more obnoxious to Charles than those of its predecessor; and afraid lest the parliament, which had already met, should exhibit a similar spirit, he lost no time in proroguing it. But nothing could now arrest the march of public sentiment; and in the parliament, which met in June 1640, in direct opposition to the wishes of the king, who had determined to prorogue it, every enactment of the General Assembly respecting the Covenant and the presbyterian faith obtained the sanction of that supreme court, and became the law of the land.

Thus the Covenanters, after an arduous struggle of three years, saw their object fully gained; namely, their favourite ecclesiastical polity established, and the validity and authority of the Covenant recognised by the legislature. Their history from this date (which will be found more at length under the article PRESBYTERIANS) becomes that of the presbyterian church in Scotland, and is interwoven with the annals of their country. Charles, offended with the triumph of the Covenanters, again declared war against them; but after a short campaign, unfavourable to the royalists, peace was restored (1641) The king having, meanwhile, alienated the affections of his English subjects, and a civil war having, in consequence, broken out, the Covenanters, on the repeated and urgent application of the parliament of England, made common cause with them, and took up arms for the third time against royal authority. But along with a civil league the Scots succeeded (1643) in carrying a religious covenant, known in history under the name of the *Solemn League and Covenant;* an obligation which was long revered in both divisions of the island, and the main object of which was to accomplish uniformity of religious doctrine and church government in both kingdoms. Nor was this object long in being, so far, attained: a presbytery, as it existed in Scotland, having obtained the sanction of the famous Assembly of Divines met at Westminster (1643-9), and having been afterwards ratified by the English parliament, was recognised as the national church of both portions of the empire. Presbytery, however, was introduced into England rather as an experiment than a permanent institution. Besides, it was not systematically adopted except in London and Lancashire; and it rapidly declined, having been, to a considerable extent, superseded by Independency. But at the Restoration episcopacy triumphed over both these forms, and has since prevailed as the established church in England. (*Solemn League and Covenant* appended to the *Westminster Confession of Faith*, edit. 1815; *Acts of General Assembly; Wodrow, Baillie, Laing.*)

Though the presbyterians had, meanwhile, differed somewhat in opinion as to some public matter, and though they were not all equally zealous in favour of the Covenant, yet the importance of this obligation was never lost sight of. On the martyrdom of Charles I. the Scots refused to recognise the right of his son, Charles II., to the throne, till he consented to subscribe the Covenant, and to guarantee and uphold the presbyterian church. Cromwell, though he allowed them the free exercise of their religion, never was the object of their affections and confidence, inasmuch as he was a sectary, and a friend to toleration, which latter they had uniformly condemned. But the Protector, while he tolerated the presbyterian faith, deprived it of some of its most valuable attributes. He not merely interdicted the meetings of the General Assembly*, but prohibited the tender of the Covenant or any similar obligation, and divested some of the ecclesiastical penalties, such as excommunication, of their terrors by depriving them of their civil effects. But a worse fate yet awaited the Covenant. At the Restoration, not only was episcopacy restored and presbytery superseded as the national church; but by a sweeping act, called the *Act Rescissory*, passed in 1661, all the parliaments that had been held since 1640 were declared null and void; thus rendering invalid those acts, in confirmation both of the Covenant and of presbytery, to which the late king had assented, and which Charles II. himself had sworn to maintain. From this period the Covenant may date its decline. It continued, indeed, to be regarded as sacred by perhaps the most valuable, if not the most numerous, portion of the clergy and people, — of those who would submit to no compromise, and who, in consequence, were the objects, during the reigns of Charles and his brother James, of the most ruthless persecution. Nay, so far did some of these parties carry their opinions, that they did not regard any person entitled to homage as king unless he had "covenanted," or affixed his signature to the Covenant. The party by which such a principle was professed are known in history under the name of Cameronians; a body which, though now much reduced both in numbers and importance, and who have moderated or changed their sentiments on this subject as well as on others, still exist in Scotland as a distinct religious sect. (*See* CAMERONIANS.) At the Revolution, when presbytery was revived in Scotland and established as it now obtains, no mention was made of the Covenant either in the General Assembly or inferior courts. It seems to have been allowed to fall into desuetude, no steps having been taken with regard to it. It now exists only as a matter of history; though, as just said, the Cameronians may be regarded as the successors and descendants of the Covenanters of the 17th century. (Ib.)

* The General Assembly had met annually from the year 1638 to 1649 inclusive. It sometimes met without having the sanction of the king, or without his majesty being represented in it, as is usual, by a commissioner. Not merely the Covenanters, but Presbyterians in general, laid it down as a principle, that the church courts are, in matters ecclesiastical and religious, independent of civil authority, and irresponsible to it. Accordingly, in 1638, the Assembly continued its sittings even after it had been dissolved by the royal commissioner. Cromwell in 1653 caused the General Assembly, then sitting, to be summarily dismissed, and interdicted its meeting in future. In this instance, the Assembly had implicitly to obey. This judicatory did not again meet till after the Revolution. (*Baillie's Letters*, ii. 369-70.)

CO'VERTS. In Ornithology. "The lesser coverts" (*tectrices primæ*) are small feathers which lie in several rows on the bones of the wings. The "greater coverts" (*tectrices secundæ*) are the feathers that lie immediately over the quill-feathers and the secondaries. "The under coverts" are the feathers that line the inside of the wings.

CO'VERTURE. In Law, the legal condition of a married woman. *See* MARRIAGE, LAW OF.

CO'VERT WAY, or COVERED WAY. In Fortification, a road or space of ground on the outer edge of the ditch, level with the adjacent country, and ranging all round the works. It is usually about 30 feet broad, and is protected by the glacis. Sometimes it is called the corridor.

CO'VEY. An old bird with her young ones; but generally used to designate a number of partridges or other game. It also in some countries signifies a cover for game.

CO'VIN. In Law, a compact between two or more, to deceive or prejudice others in certain cases; as, if tenant for life or in tail conspire with another party, to the intent that such party may recover lands held by the tenant to the prejudice of him in reversion.

COW'HAGE, COWITCH. This term is generally applied to the hairs or spiculæ which cover the seed pods of the *Mucuna pruriens*, a climbing perennial plant, which is a native of the East and West Indies. An electuary formed by dipping the pods into treacle, syrup, or despumated honey, and then scraping them, has long been used as a vermifuge; but it is often a very troublesome remedy, from the excessive itching which it produces when it touches the unprotected skin, and there are other more effectual means of expelling worms.

COW'-KEEPER. A person whose business it is to keep a stock of cows for supplying the public with milk and cream. The principal cow-keepers of the metropolis have their establishments in the suburbs, where they are connected with pasture fields, in which the animals are turned out a portion of every day throughout the year, excepting when the ground is covered with snow, or when it rains very hard. The cows are fed in the house with grains, mangold wurzel, hay, tares, and other kinds of nourishing food; and as the animals get air and exercise, their milk may be considered wholesome. There are many cow-keepers, however, in the metropolis, who keep only a few cows in confined back houses, and even in dark cellars; and, while they feed them with rich food, give them no exercise at all: hence the milk of such cows cannot be considered as wholesome.

COW POX. This disease was proposed in the year 1798 as a substitute for, and preventive of, the small pox by Dr. Jenner; and subsequent experience, as well as the extent to which the inoculation of it, or *vaccination*, as it is called, is carried throughout the civilized world, furnish well-grounded hopes of the ultimate extinction of one of the severest visitations of the human race. Small bluish vesicles, surrounded by inflammation, elevated at the edge and depressed in the centre, and containing a limpid fluid, occasionally appear upon the teats of the cow, the animal being at the same time somewhat indisposed: a similar disease is transferable under certain circumstances to the hands of the milkers; and persons who had so received it were found to be in many instances unsusceptible of small pox, both natural and inoculated. There is a disease of the horse's heel called

grease, which appears to have produced similar effects upon the hands of farriers, and is perhaps the origin of the cow's disease: but it is from the latter animal that the *matter* is most certainly effective, and from which it is transferred to the human race, where it produces similar pustules; and the fluid of these may again be transferred with the same effects from one human subject to another. Whether by continuous circulation through human subjects the *virus*, as it is called, gradually loses its preventive efficacy, is an important question, and one upon which there are differences of opinion; but it would probably be more safe if more frequently derived from its original source upon the cow's teat. It seems useless here to discuss the various objections which have been raised, and the suspicions which have been thrown out against the permanent efficacy of this preventive, since the most extended and unbiassed experience of the most skilful observers seems amply to have proved that *when the pustule has gone through its regular stages*, the person is afterwards, during the whole period of life, unsusceptible of natural and of inoculated small pox, the exceptions to this statement being so few as either to be referable to imperfect vaccination, or to idiosyncracy; and though it is not pretended that cases of small pox after vaccination are as rare as of small pox after small pox, yet it is well known that the latter do occur, and, in short, that there is no rule without exceptions. In doubtful cases vaccination should always be repeated; and as no inconvenience results from a repetition of its inoculation, and the disease is not infectious by effluvia, it may be performed at certain intervals, or may even be tested as to its efficacy by *variolous* inoculation; although to the latter there are certainly serious objections, if we look to its ultimate extermination. In inoculating patients for the cow pox the matter should be taken from a healthy child, at about the 6th or the 8th day, at which time the pustule is well formed; and it should be immediately transferred upon the point of the lancet from the pustule to the arm, and inserted by a small oblique puncture under the cuticle, one place in each arm being quite sufficient. If this direct mode cannot be followed, the virus intended for inoculation may be transferred between two pieces of plate glass, one of which is slightly indented for its reception; when slid over each other they are air-tight, and the edges may be secured by a strip of moist gold-beaters' skin or very thin bladder. If it is necessary to moisten the virus, this should be done with as small a portion as possible of tepid water, not exceeding the temperature of 100°. Lancet points which have been *armed*, as it is called, cannot be long depended upon, and are apt to be rusted and to irritate the arm. About the third day after inoculation the puncture generally becomes red and elevated, but the periods of its incipient progress are very uncertain; it then continues to enlarge and become vesicular; and is in full perfection about the eighth or ninth day, at which period also the surrounding circle of inflammation or *areola* is at its height. About the eleventh or twelfth day this declines, and the centre of the pustule becomes brown, and gradually dries up into a dark-brown circular scab, depressed in the centre. During the progress and scabbing off of the pustule great care should be taken to avoid all external injury; all irregularities in its progress should also be carefully watched; and if much inflammation comes on spontaneously two on or three days after inoculation, and especially if suppuration ensues, the probability is that the operation has failed; and in all cases where there is the least doubt the inoculation should be repeated, although, if one of the pustules has gone through the above described progress, the failure or irregularity of the other is of no consequence. The cow-pock is seldom attended by any symptoms requiring medical aid; but generally there is a slight drowsiness and febrile symptoms, with some restlessness, and occasionally sickness, about the second and third days; but these symptoms are immaterial to the preventive efficacy of the virus, which can only be judged of by the appearance and progress of the pustules, to which therefore it is necessary to pay close attention.

COW'RIES. (Germ. kouri.) Small shells brought from the Maldives, which pass current as coin in smaller payments in Hindostan, and throughout extensive districts in Africa: 100 are equivalent to a penny.

COY'POU. A Rodent quadruped; the *myopotamus* of geologists. *See* Nutria.

CRAB. *See* Cancer.

CRA'BRO. (Lat. crabro, *a hornet.*) A genus of Hymenopterous insects, belonging to the section *Aculeata* or sting-bearers, and to the subsection *Fossores* or burrowers. The hornet (*Crabro vulgaris*) is the type of this genus, which is now raised to the rank of a family (*Crabronidæ*), including two groups of subgenera. In one of these groups all the species have their fore-legs provided with strong spurs, for the purpose of excavating in decayed wood, or burrowing in sand, to form cavities in which their eggs are deposited; the insects of the other section have the fore-legs unarmed, and form no burrows, but deposit their eggs in the nests of other species. The true hornets (*Crabro*) excavate their retreat in wood, and feed their larvæ with the caterpillars of small moths found upon the oak, as well as with flies.

CRA'DLING. (Sax. cpaðel.) In Architecture, the timber ribs in arched ceilings and coves to which the laths for the plaistering are nailed.

CRAFT. *See* Trade and Vessel.

CRAG. A provincial name applied in Norfolk and Suffolk to certain accumulations of gravel.

CRAMP. Spasmodic or involuntary contraction of some of the muscles, often attended with great pain; it is common in the muscles of the leg and foot, especially after any extraordinary exertion of them, and is sometimes brought on apparently by irritation in the stomach of indigestible food. When cramp seizes the calf of the leg, it usually goes off upon placing the limb in an erect posture and rubbing the affected part: those subject to it find much relief by applying opiate liniments. If it arises from indigestion, or from indulgence in acescent drinks or champagne, mild bitters with magnesia, taken at bed time, will generally prevent its recurrence.

Cramp. (Dutch kramp.) In Architecture, a piece of metal, bent or dovetailed at each end, for the purpose of holding two blocks of any material firmly together.

CRANE. (Sax. cpan.) In Mechanics, a machine for raising heavy weights, and depositing them at some distance from their original place; for example, raising bales from the hold of a ship, and depositing them on the quay. A jib or transverse beam, inclined to the vertical in an angle of 40° or 50°, is constructed, which, by means of a collar, turns on a vertical arbor. The upper end of the jib carries a fixed pulley, and the lower end a cylinder, which is put in motion by a wheel and pinion, or cog wheel, or merely with a handle. The weight is made fast to a rope which passes over the pulley and is wound round the cylinder. On turning the cylinder, the weight is raised as far as necessary; the jib is then turned on its arbor till the weight is brought immediately over the spot where it is to be deposited; when, by withdrawing the moving power, it is allowed to descend by its own gravity. Cranes may be constructed of immense power. They are generally turned by human force; sometimes, however, by a steam engine.

CRA'NGON. (Gr. κραγγη, *a cray-fish.*) The name of the genus of Macrourous Crustaceans, including the common shrimp (*Crangon vulgaris*, Fabr.) This species abounds most on sandy coasts, and is caught by means of a large open net fixed to the end of a long stick.

CRANIO'LOGY. *See* Phrenology.

CRA'NIUM. (Gr. κρανιον, *the skull.*) Sometimes applied to the entire bony compages of the head of the vertebrate animals; but, in Human Anatomy, is restricted to that portion of the skull which surrounds the brain.

CRANK. A mechanical contrivance for changing a revolving into an alternate motion. An iron axis is bent in some part of its length out of its rectilinear direction. As the axis turns the bent part describes the circumference of a circle, and gives a reciprocating motion to a piston or rod attached to it.

Crank. (Germ. krank, *sick.*) In Nautical language, a ship is said to be *crank*, when by the form of its construction, or by want of a sufficient quantity of ballast or cargo, or by being loaded too much above, it is incapable of carrying sail without being exposed to the danger of oversetting.

CRAPE. A species of gauze made of raw silk woven without crossing; it is stiffened with gum-water.

CRASSULA'CEÆ. (Crassula, one of the genera.) A natural order of herbaceous or shrubby Exogens, growing in hot, dry, and exposed situations; remarkable for the succulent nature of their stems and leaves. They have an affinity with *Penthorum* and with *Illecebraceæ*, through *Tillæa*; and possess refrigerant abstergent properties, mixed at times with a good deal of acridity.

CRA'TER. (Gr. *a large cup* or *bowl*, used in antiquity during a repast, for holding mixed wine and water.) The mouth of a volcano, which see.

CRAYO'NS. Coloured cylinders used for drawing upon paper; they are usually made of a fine pipe-clay, coloured with metallic pigments or carmine. Crayons containing plumbago are styled *solid lead pencils*.

CREAM. (Fr. crême.) A semifluid yellowish substance which collects on the surface of milk, and which is made into butter by the process of churning. When the milk of any animal is allowed to stand for some time it spontaneously undergoes certain changes; this substance rises to the surface, and forms a thin stratum, which is called cream, and which consists chiefly of oily particles; while the milk below, which of course is thinner than it was before the cream separated from it, is of a pale bluish colour, and consists of curd, coagulum, or the matter of which cheese is made. When cream is kept for some days it gradually becomes thicker, and partially coagulated; and if put into a linen bag and suspended from the ceiling of a cool room, it will acquire the consistence of cheese; and this is one among other modes of making cream cheeses. When cream is shaken

by churning it is resolved into its component parts, and hence we have butter and buttermilk. In order to make butter it is not always necessary that the cream should be separated from the milk; but whether separated or not, the process is facilitated by allowing the liquid to stand for some time, during which a part of the sugar contained in the serum is changed into an acid, which shortens the process of churning by facilitating the separation of the butter from the milk. When either cream or milk is churned without having previously become sour, the process is much more tedious; and sometimes, from causes not easily accounted for by the dairymaid, it is unsuccessful, and the milk is said to be bewitched. The true cause, however, is the want of acidity; because it has been found that the addition of a small portion of vinegar will dissolve the charm, and cause the almost immediate appearance of butter. Cream, when separated from milk and kept still it has become acid, is frequently mixed with milk newly drawn from the cow; and this eaten with sugar is one of the most delicious preparations of the dairy. Costorphin cream, so called from a village of that name in the neighbourhood of Edinburgh, is made by putting the milk of three or four days together with the cream into a vessel, and allowing it to remain there till it has become sour and coagulated. The whey is then drawn off and fresh cream added; and when it is brought to table it is eaten with sugar, and in the strawberry season with that fruit. Devonshire cream is simply sour curd, or sour cream eaten with fresh milk, or fresh cream, with or without the addition of sugar. Devonshire scalded or clouted cream is milk and cream heated to the boiling point, and suffered to cool, when the cream will be found to have separated from the milk, and when skimmed off may either be made into butter or eaten with fresh cream and sugar. Common clotted cream is simply milk and cream in a coagulated state, and sour. When the clotted cream is broken and stirred, and the whey drawn off, the mass may be turned into cheese by artificial pressure, by which the whey is separated instantaneously; or by suspending it in a porous bag, in a cool airy situation, when it will be separated by degrees. *See* Butter, Cheese.

CREDE'NTIALS, LETTERS OF. The instrument in the form of a letter, from one monarch to another, which constitutes the evidence of the title of a minister at a foreign court to the power which he exercises. There are two sorts of credentials: the one sealed, drawn up and countersigned by the minister of foreign affairs; the other open, signed only by the king. Unless the minister be mentioned expressly in his credentials as an ambassador, he has only a right to the observances due to foreign ministers of inferior rank.

CRE'DIT, in Political Economy, is a term used to express the lending of wealth, or of the means of acquiring wealth, by one individual or set of individuals to another. The party who lends is said to give credit, and the party who borrows to obtain credit. Hence credit may be defined to be the acquisition by one party of the wealth of another in loan, according to conditions voluntarily agreed on between them.

Very exaggerated notions are commonly entertained of the influences of credit; but, in fact, all operations in which credit is given or acquired resolve themselves into a new distribution of wealth already in existence. The "magical" effect that is every now and then ascribed to credit is quite imaginary. A party who purchases goods payable at some future date obviously acquires the command of so much of the capital of the seller of the goods as their value amounts to, in the same way that a party who discounts a bill acquires the command of a corresponding portion of the capital of the discounter. Wealth is not created by the issue of bills; and all that their negotiation does is to transfer already existing property from one individual or party to another.

In the great majority of cases loans are made by individuals who wish to retire from business, or who have more capital than they can advantageously employ, to individuals entering into business, or who wish to extend their concerns and to acquire a greater command of capital. The probability is, that capital will be more likely to be efficiently employed by the latter than by the former class of persons; and the advantage of credit, in a national point of view, consists in that circumstance. Loans made to prodigals or spendthrifts, or to individuals who expend them on unprofitable undertakings, are, in so far, publicly injurious; but, speaking generally, these bear but a very small proportion to the other class of loans, or those made to individuals by whom they are advantageously expended.

Public credit is the phrase used to express the trust or confidence placed in the state by those who lend money to government.

The interest or premium paid by the borrowers to the lenders depends on a great variety of circumstances,— partly on the rate of profit that may be made by the employment of capital at the time, partly on the duration of the loan and the security for its repayment, and partly on the facilities given by the law for enforcing payment. The only way, indeed, in which a government can advantageously interfere to encourage credit is by simplifying the administration of the law, and by giving every facility for carrying the conditions of contracts into effect.

CRE'DITOR. *See* Bankruptcy.

CREED. Any brief summary of Christian belief; but more especially either of the three confessions commonly called the Apostles', Nicene, and Athanasian. The term is derived from the word credo, *I believe;* in like manner as paternoster, avemaria, &c., are prayers named from the first word of these formulas in the Latin tongue.

CREEK (Sax. crecca, said to be derived from the Lat. crepido), is a shore or bank on which the water beats, running in a small channel from any part of the sea. It is also applied to any part of a large river which is resorted to as a harbour or landing place by small craft. In the United States, the term creek is used as synonymous with our English words brook or rivulet.

CREEL. A kind of basket; such, for instance, as is used by anglers.

CRE'MOCA'RPIUM. (Gr. κρεμαω, *I suspend*, and καρπος, *fruit.*) A two to five-celled inferior fruit, the cells of which are one-seeded, indehiscent, dry, perfectly close at all times, and when ripe hanging separate from a common axis, as in umbelliferous plants.

CREMO'NA. A general designation of the violins made at Cremona in Italy, during the 17th and 18th centuries, chiefly by the family Amati. (*See* Violin.) Cremona is also a name erroneously given to a stop in the organ; being nothing more than a corruption of krumhorn, an ancient wind instrument, which it was originally designed to imitate.

CREO'LE. (In Spanish Criollo.) A name given to the descendants of whites born in Mexico, South America, and the West Indies; in whom the European blood has been unmixed with that of other races. The various jargons spoken in the West India islands by slaves, &c. are called Creole dialects.

CRE'OSOTE, or KREASOTE. A colourless, transparent, oily liquid, separable from wood-tar: it appears to be the principle to which the antiseptic power of wood-tar, smoke, and crude pyrolignous acid is owing. Hence its name, from κρεας, *flesh*, and σωζω, *I save.*

CRE'PITUS. (Lat.) The crackling noise which is produced upon pressing cellular membrane when it contains air.

CRESCE'NDO. (It.) In Music, a direction to the performer to increase the volume of sound from soft to loud; marked thus $<$.

CRE'SCENT (Lat. cresco, *I increase*), in Heraldry, is a bearing in form of a half moon. When the horns are turned towards the chief or upper part of the shield, it is called *crescent*, in contradistinction to the terms *increscent* and *decrescent;* in the former of which the horns are turned to the right, and in the latter to the left side of the shield. The crescent is frequently used to distinguish the coat armour of a second brother or junior family from that of the principal branch. As is well known, the crescent, or, as it is usually designated, the *crescent montant*, has become the symbol of the Turkish empire, which has thence been frequently styled the Empire of the Crescent. This symbol, however, did not originate with the Turks. Long before their conquest of Constantinople the crescent had been used as emblematic of sovereignty, as may be seen from the still existing medals struck in honour of Augustus, Trajan, and others, and it formed from all antiquity the symbol of Byzantium. On the overthrow of this empire by Mohammed II., the Turks, regarding the crescent which every where met their eye as a good omen, adopted it as their chief bearing; and it has continued ever since to decorate their minarets, their insignia, their dress, and in short every thing appertaining to their empire. Crescent has also been applied to three orders of knighthood: the first of which was instituted by Charles I., king of Naples and Sicily, in 1268; the second by René of Anjou, in 1448; and the third by the sultan Selim in 1801, two years after the battle of Aboukir. The last-mentioned order is still in existence, and is remarkable for the fact that none but Christians are eligible for admission.

CRE'ST. (Lat.) In Heraldry, the ornament affixed to the helmet, being a personal or hereditary device. Warriors bore insignia peculiar to themselves in this manner among the classical ancients. The earliest instance of the heraldic crest in England is said to be that of Edmund Crouchback, Earl of Lancaster (about 1280). The crest is, in modern blazonry, a figure placed upon a wreath, coronet, or cap of maintenance, which surmounts the coat of arms. It is not unfrequently a repetition of some bearing in the shield itself; as, the crest of Castile is a castle.

CRETA'CEOUS. (Lat. creta, *chalk.*) Composed of chalk. In Geology, the *cretaceous group* of rocks includes the upper strata of the secondary series, immediately below the tertiary deposits, and resting upon the oolitic group. (See *Fitton*, in *Geol. Trans.*, 2d Series, vol. iv.)

CRE'TINS. A name applied in the Valais and elsewhere to a class of idiots, who are also generally afflicted with *goitres*, which see.

CRIB. Sometimes applied to a rack for hay or straw for cattle, and sometimes to a manger for corn or chaff; also to a small enclosure in a cow-house or shed for calves or sheep.

CRIB-BITING. Biting the manger or crib; a bad habit among horses, brought on by uneasiness occasioned by diseases of the teeth, or by roughness in the person who currycombs them.

CRI'BBLE. A coarse sieve, or screen, for sifting sand, gravel, or corn; the term is also applied to a sort of coarse meal.

CRI'COID. (Gr. κρικος, *a ring*, and ειδος, *appearance*.) Annular or ring-shaped. A cartilage of the larynx is hence called the *cricoid cartilage*.

CRI'NO. A cuticular disease, supposed to arise from the insinuation of a *hair-worm* under the skin of infants.

CRINOI'DEANS, *Crinoidea*. (Gr. κρινον, *a lily*, and ειδος, *appearance*.) A name given by Miller to an extinct family of Echinoderms, having a radiated, lily-shaped disc, supported on a jointed stem. When this stem is cylindrical, the species are termed *Encrinites*; when it is pentagonal, *Pentacrinites*. See those words.

CRI'SIS (Gr. κρισις, *a decision*), may be defined, in its most extended signification, as a decisive point in any important affair or business; but it is used more particularly in a political sense, to denote a certain conjuncture of affairs in which, from what cause soever it may have originated, the ordinary operations of government are so fettered or deranged as to lead to some important change in the policy or institutions of a country. Like many expressions of similar import, the phrase "political crisis" admits of an almost endless variety of shades of meaning, being applicable at once to a change of ministry, the abolition of a constitution, a revolutionary insurrection, and the dethronement of a sovereign. Hence this expression will be better interpreted by the feelings, predilections, or prejudices of each individual, than by any definition of which it is susceptible. In France, a "crise politique," as it is called, is synonymous with the terms *coup d'etat*, *emeute*, *revolution*, *insurrection*, &c. In Medicine, certain symptoms which announce a favourable or an unfavourable termination of a disease are called *critical symptoms*, and the period at which they show themselves the *crisis* of the disease. In the progress of fevers these symptoms have been supposed to show themselves at certain definite periods, which therefore have been called *critical days*.

CRI'TICAL PHILO'SOPHY. The metaphysical system of Kant is sometimes so termed, from his famous work, the *Kritik der Reinen Vernunft* (Criticism of Pure Reason). *See* KANTIAN PHILOSOPHY.

CRI'TICISM (Gr. κρινω, *I judge*), has been defined "the art of judging with propriety concerning any object, or combination of objects." In a somewhat more limited, but still extensive meaning, its province is confined to literature, philology, and the fine arts; and to subjects of antiquarian, scientific, or historical investigation. In this sense, every branch of literary study, as well as each of the fine arts, has its proper criticism as an appendage to it. The elements of criticism depend on the two principles of Beauty and Truth, one of which is the final end or object of study in every one of its pursuits: Beauty, in letters and the arts; Truth, in history and the sciences. The office of criticism, therefore, is, first to lay down those forms or essential ideas which answer to our conception of the beautiful or the true in each branch of study; and, next, to point out by reference to those ideas the excellences or defects of individual works, as they approach or diverge from the requisite standard in each particular. Thus, historical criticism teaches us to distinguish the true from the false, or the probable from the improbable, in historical works; scientific criticism has the same object in each respective line of science; while literary criticism, in a general sense, has for its principal employment the investigation of the merits and demerits of style or diction, according to the received standard of excellence in every language; and, in poetry and the arts, criticism develops the principles of that more refined and exquisite sense of beauty which forms the ideal model of perfection in each. Taste is the critical faculty; that perception of the beautiful in literature and the arts, for the acquisition of which, perhaps, some minds have superior natural powers than others, but which can in no instance be fully developed except by education and habit. (*See* ÆSTHETICS.) Among the classical ancients, the criticism of Beauty was carried to a high degree of perfection. Less encumbered with a multitude of facts and things to be known than ourselves, their minds were more at leisure, and more sedulously exercised in reflecting on their own notions and perceptions; hence the astonishing progress which they made in the fine arts; and hence, in literature, they valued more the beauty of the vehicle in which sentiments were conveyed, and the moral or poetical beauty of those sentiments themselves, than the objective branches of study which it is the principal purpose of literature, in our days, to convey easily and precisely to the mind. And as the criticism which antiquity has left us consists almost wholly of such as relates to literature and the arts (in history they had, as far as we know, few critical spirits, in the sciences almost none), the name is still confined, in its most popular signification, to those provinces of research. The criticism of Truth is of later growth; but as it is regulated for the most part by similar rules and principles, and as minds which possess the faculty of judgment in a high degree in the one are generally capable, if exercised, of forming right apprehensions in the other, they may be considered as nearly allied in the more essential respects. For although it is true that in scientific investigation great knowledge of the individual subject is required to constitute a critic, and in the fine arts the most gifted mind will require much education and practice to judge of beauty; yet it is equally true in both of these branches of study, however widely differing from each other, that knowledge alone (except perhaps in purely abstract science, in respect of which the name of criticism seems hardly applicable) will not make the critic, and that the habit of discriminating and judging correctly is a distinct faculty or compound of faculties in the mind. Among a host of works which may be consulted with advantage on this subject, are *Blair's Lectures on Belles Lettres; Campbell on Rhetoric; Whately on Rhetoric; Knight and Alison on Taste; Laharpe, Cours de la Litterature; La Cretelle, Traité de la Rhetorique; Horn and Menzel's History of Polite Literature;* and *Schlegel's Miscellaneous Essays*, &c. *See* BELLES LETTRES and RHETORIC.

Criticism, in a more limited sense, is a branch of belles-lettres. Essays written for the purpose of commending or discommending works in literature or the arts, and pointing out their various merits and defects, are works in the critical department. Thus the term "periodical criticism" is used to express the body of writing contained in the various works under the name of magazines, reviews, &c., which are periodically published in most literary countries.

CRO'CKETS. (Fr. crochet, *a hook*.) In Gothic Architecture, ornaments resembling curved and bent foliage running up on the edge of a gable or pinnacle. They are of two varieties: the earliest are formed by a simple curve turning downwards, as in the gables and spires of Lincoln cathedral; the later have the point of the leaf returned and pointing upwards. Sometimes animals are substituted in the place of leaves.

CRO'CODILES. (Gr. κροκοδειλος.) A name first applied by Herodotus to the crocodile of Egypt, because that animal resembled a small lizard of the same name (*Stellio* of the moderns), which is now known in Greece under the name of *Koslordylus*. The Egyptian and other species of crocodile were confounded by Linnæus under the name of *Lacerta crocodilus*; but the crocodiles are distinguished from all other Saurian reptiles, or *Lacertæ* of Linnæus, by the following characters:—They have a long and powerful tail, which is flattened in the vertical direction, to serve as the principal means of propelling the body through water with the swiftness required in the pursuit of fish, which form the principal prey of the crocodile. The extremities are short, and comparatively of little use in aquatic progression, except in guiding and changing the direction of the motion, for which purpose they are always webbed or half-webbed. The fleshy tongue is attached by its entire marginal circumference, as in most fishes, to the inner side of the lower jaw, and is not extensible, as is the case in all true lizards. The teeth are simple, conical, sharp-pointed, large, lodged in distinct sockets, and arranged in a single row; which structure and disposition are in relation with the carnivorous habits of the crocodile. Lastly, the intromittent organ of the male is single.

To these essential differences between the crocodiles and lizards may be added the following characters, which are common to all the crocodiles:—

1. The fore-feet have five toes; the hind-feet four toes.
2. Three toes only on each foot are armed with claws; so that there are two toes in front and one behind which have no claws.
3. The whole of the tail and the upper and under parts of the body are covered with square scutæ or plate-scales; and the greater number of those on the back are traversed longitudinally by a more or less prominent ridge.
4. The sides of the body are covered with small round scales.
5. The ridges on the scales of the tail form at its base two prominent lateral series, or dentated keel-like crests, which converge and blend into one at the posterior part of the tail.
6. The tympanum or drum of the ear is protected by two moveable flaps.
7. The eyes are provided with three eyelids.
8. Two little pouches containing a substance of a musky

odour. Their anatomy also affords some characters which are common to all the species, and very well distinguish their skeleton from that of other Saurians. The ventricles of the heart do not intercommunicate. The vertebræ in the cervical region support a series of spurious ribs, which are directed backwards, and the extremities of each overlapping the next in succession prevent the animal from turning the head to the side. This structure, it will be seen, is in admirable accordance with the aquatic habits of these large piscivorous reptiles; since, in order to displace the fluid medium through which they move, it is essential that the head should be firmly locked to the trunk. It is for this reason that the vertebræ immediately behind the head in fishes bear ribs; and the cervical vertebræ of the whale, although they accord in their number and in the absence of ribs with those of other mammalia, are modified so as to answer the same end as the costo-cervical vertebræ of crocodiles and fishes, being compressed from before backwards, and anchylosed sometimes into a single piece.

CROFT. A small field adjoining the dwelling house and kitchen garden. The term is also sometimes applied to common field lands.

CRO'MLECH, or CROMLEH. In British Antiquities, large flat stones laid across others in an upright position; very commonly found in parts of Wales, in Devonshire and Cornwall, and other exposed districts of England, as well as in some continental countries. Cromlechs are generally supposed by antiquaries to have been constructed to serve as altars. According to some (see *Fosbrooke's Encyclopædia of Antiquities*, 508.) there is a difference between the cromlechs of the Britons and those of nations of Germanic descent; the former being inclined stones, perhaps for the purpose of allowing the blood shed in sacrifice to run off; the latter thick round stones, standing on small hillocks and covering caves.

CROP OUT. A mining and geological term, expressing the rising up or exposure at the surface of a stratum or series of strata.

CROPS, ROTATION OF. *See* AGRICULTURE.

CRO'SIER. The staff of an archbishop, surmounted by a cross, and thereby distinguished from the pastoral staff or crook of a bishop. This staff, according to Polydore Virgil, was given to bishops wherewith to chastise the vices of the people; and was called *baculus pastoralis*, in respect of their pastoral charge and superintendence over their flock, as well as from its resemblance to the shepherd's crook. Many authors contend that the crosier is derived from the *lituus* or augural staff of the Romans.

CROSS. (Lat. crux.) A gibbet made of two pieces of wood laid upon each other at any angle. Originally, it was nothing more than a tree; but it afterwards assumed a variety of forms, of which the following are the most usual examples, × ⊤ †. The cross was used as a very general instrument of punishment by almost all the nations of antiquity, from the earliest period of their history. Among the Syrians, Jews, Egyptians, Persians, and especially the Carthaginians, it appears to have been the usual military punishment (*Val. Max.* ii. 7.; *Herod.* iii. 125—159.); and that it was not unknown to the Greeks, the crucifixion of 2000 Tyrians by Alexander after his capture of their city abundantly testifies (*Quin. Cur.* 44.; *Just.* 18. 3.) But in no part of the ancient world was this punishment so generally resorted to as in the Roman empire. Under the early monarchical government of Rome, it extended indiscriminately to every rank (*Liv.* i. 26.); but latterly it came to be regarded as the most infamous of deaths, and, save in cases of sedition, was inflicted only on slaves or the vilest malefactors. The disgust and horror in which this punishment was held by the Romans is evident from the expressive epithets applied to it by Cicero, "crudelissimum et teterrimum" (*most foul and brutal*), as well as from the phrases used synonymously with the instrument of punishment itself; such as "arbor infelix," "infame lignum," &c. From the multiplicity of conflicting details respecting the punishment of the cross, it is clear that there was but little uniformity observed in carrying it into effect. By the Roman law the culprit, or, as he was called, the *cruciarius*, was scourged previously to the crucifixion either in the prætorium, or on the way to the place of execution. On his arrival there he was stripped of his garments, and then either nailed by the hands and feet to the cross, or, as sometimes happened, only fastened to it by ropes. In order to hasten death, it was the practice to break the legs or to pierce the body of the sufferer with a spear or other sharp instrument; but this was not always done; and instances have occurred of persons, who after being suspended for some considerable time on the cross, were taken down and survived. By the Jewish law, it was ordained, that the body of the culprit should be removed from the cross on the day of his execution; but the Romans frequently allowed it to hang till it dropped piecemeal to the ground and nothing remained. "Suffixorum corpora crucibus," says Seneca, "in suam sepulturam defluunt." In general, the cross was erected near some great road or highway, in order to indicate more distinctly the ignominy of the culprit and the severity of his death.

After Jesus Christ had, by an unjust sentence, suffered on the cross, and by his death made atonement for the transgressions of mankind, the cross, from being an object of horror, became, as it were, the symbol of the Christian world, and in the end came to be regarded even with superstitious veneration. Constantine, from respect for these feelings, abolished the punishment of crucifixion throughout the Roman world.

The Apostles make use of the term cross as expressive of the sufferings to which the faithful must submit in attestation of their belief, which they liken figuratively to those of our Saviour in his death. Tertullian says that the early Christians were accustomed on every occasion of daily life, *frontem crucis signaculo terere*, to make the sign *with the fingers upon the forehead*. This extravagant profuseness in the use of a symbol naturally led to superstition; and the cross appears to have become the object of actual adoration as early as the 4th century, when that practice is made a reproach against the Christians by Julian. The allegation of the later Romanists, that it is not the wood of the cross, but Christ figuratively present, that is worshipped by them, appears to have been put forward occasionally at this time, but sometimes not without reproof from the ecclesiastical authorities. In the Romish church there are certain festivals observed to this day in memory of circumstances connected with the cross; as the Invention or Discovery and the Exaltation of the Cross: the former commemorates the supposed discovery of the true cross by the Empress Helena, the latter its restoration to Calvary by Heraclius.

CROSS. In Heraldry, an ordinary, formed by lines drawn palewise and fesswise, inclosing (if bounded by the escutcheon) one fifth of the shield, or one third if charged. A cross gules is termed the cross of St. George. A plain cross is one the extremities of which do not reach to the circumference of the escutcheon, but are "couped," or cut off in a straight line. There are many other kinds of crosses not reaching the circumference of the escutcheon known in heraldry; the following are only a few, most commonly used in bearings:—A *cross crosslet* is one crossed on each arm. Such a cross between four plain crosses is termed a Jerusalem cross. A *cross flory* has three points at each end. A *Maltese cross* has arms increasing in breadth towards the end, with double points. A *cross fitchy* has the lower limb pointed, as if to fix in the ground. A *patriarchal cross*, the insignia of patriarchs or archbishops, is plain, having two bars, the upper smaller than the lower. A *cross moline* terminates in representations of the ends of the fer-de-moulin, or milrind. It is the difference of the eighth son of a family.

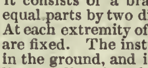
CROSS. An instrument formerly used in surveying for laying out perpendicular lines, but now seldom employed. It consists of a brass cross or circle, divided into four equal parts by two diameters at right angles to each other. At each extremity of these diameters perpendicular sights are fixed. The instrument is mounted on a staff to fix it in the ground, and its use is to find the point in a given line or direction through which a straight line drawn to an object at some distance will be perpendicular to the former line.

CRO'SS-BOW. A weapon used for shooting with, before the invention of fire-arms. All weapons having the bow attached to a stock were called cross-bows; and some of the larger sort were furnished with instruments for bending the bow.

CRO'SS-BREED. The offspring of parents of two different breeds.

CRO'SSES, STONE, in Architectural Antiquities, are of various descriptions, according to the occasion or purpose of their erection. They are said to have originated in the practice of marking the Druid stones with a cross, at the period of the conversion of the Celtic tribes to Christianity. *Preaching crosses* are generally quadrangular or hexagonal, open on one or both sides, and raised on steps. They were used for the delivery of sermons in the open air; such was the famous Paul's Cross in London. *Market crosses* are well known. *Weeping crosses* were so called because penances were finished before them. *Crosses of memorial* were raised on various occasions; sometimes where the bier of an eminent person stopped on its way to burial, in attestation of some miracle performed on the spot: such are the well-known crosses of Queen Philippa. Crosses served also as land-marks; they are especially set up for this purpose on the lands of the Templars and Hospitallers.

CROSSE'TTES. (Fr.) In Architecture, the returns on the corners of door cases or window frames; called also ears, elbows, ancones, prothyrides. In architectural construction, they are the small projecting pieces in arch stones which hang upon the adjacent stones—*a*, *a*, *a*, *a*.



CRO'SS-FURROW. A furrow or open trench cut across other furrows to intercept the water which runs

along them, in order to convey it to the margin of the field where it may find its way to an open ditch or some other general drain.

CRO'SS-STONE. So called from the intersection of its crystals. It is a species of *harmotome*, found in great beauty at Andreasberg. (*See* ANDREASBERGOLITE.) It is composed of 49 *per cent.* of silica, 16 alumina, 18 baryta, and 15 water.

CRO'TALUM. (Gr. κϱοταλον.) An ancient kind of castanet, used by the Corybantes or priests of Cybele. This instrument must not be confounded with the modern *crotalo*, a musical instrument used chiefly by the Turks, and corresponding exactly with the ancient cymbalum.

CRO'TALUS. (Lat. crotalum, *a castanet* or *rattle.*) A genus of poisonous serpents, including those which are furnished with a rattle at the extremity of the tail.

CRO'TCHET. (Fr. crochet.) In Music, one of the notes or characters of time, equal to half a minim.

CRO'TCHETS, in Grammar, more frequently called *brackets*, are certain marks or hooks in which words or phrases are included thus [ ], by way of distinguishing them from or of illustrating the context.

CRO'TON OIL. The expressed oil of the seeds of the *Croton tiglium;* formerly called *Grana tiglia*, and *Molucca grains*. The tree is a native of Ceylon, and of Malabar and the Molucca Islands. Its seeds are very purgative; and their expressed oil so drastic, that a single drop will often prove violently operative, completely emptying the bowels and exciting a copious watery secretion from them. The most active form for its exhibition is made into a pill with bread crumb: it may also be rubbed with a little mucilage of gum arabic, and given in a liquid form; but it always requires much caution in its administration.

CROUP. An inflammation of the larynx and trachea, accompanied by difficulty of breathing and cough, and by a peculiar shrillness of voice and wheezing; there is also generally more or less expectoration of purulent and filmy matter, which is thrown out upon the affected part and continually threatens suffocation. This disease is most common in infants, and in children from three to nine years old; it is of rare occurrence, in its acute form at least, after twelve years of age. In the successful treatment of this distressing and dangerous disease, every thing depends upon promptitude in the application of remedies calculated to subdue the local inflammatory action. This is to be done either by leeches to the region of the trachea, by cupping, or by bleeding in the jugular vein; by the cautious application of external irritants of rapid action, such as a piece of lint dipped in strong acetic acid, which, however painful, is sometimes of service; by blisters, and by the exhibition of large doses of calomel: there is a difference of opinion as to the employment of emetics. The inhalation of steam is useful where it can be resorted to, but in young children it is impracticable. In *spasmodic croup* the wheezing and sense of suffocation appear to depend upon spasmodic action of the larynx or epiglottis: like the former it attacks infants and children, but comes on and goes off very suddenly, returning at intervals, during which the patient is comparatively easy. In weakly and irritable children it sometimes appears a consequence of teething. An emetic, calomel purges, warm bath, diaphoretics, and a blister, are the leading remedies; bleeding should be avoided. There is a kind of croup which sometimes attacks children of weakly constitutions, and which appears symptomatic of irritation in the stomach and bowels, for it is relieved by purging, and disappears as the constitution improves. Another form of this disease is called *chronic croup*. It is attended by cough and the expectoration of tough mucus, sometimes apparently membranous or tubular, occasioning difficulty of breathing and suffocation. This disordered state of the trachea and bronchial membranes may occur at all periods of life: it is relieved, and often cured, by using the inhaler with warm water, by expectorants with small doses of sedatives and mercurials, and by occasional purging.

CROWN. (Lat. corona.) In Heraldry. Among the ancients, and especially in the Roman republic, crowns were presented to citizens as marks of distinction for valiant or otherwise meritorious exploits. From this usage the crown has been adopted as a bearing by modern heralds. Nine species of the crown are enumerated in heraldry; some of which, however, have not been introduced into modern arms, and are only known from the description left of them by the ancients:—1. The Eastern Crown, imitated from that which appears on coins of Greek oriental sovereigns, and borne by those who have distinguished themselves in the East: the East India Company's arms have this crown. 2. The Triumphal Crown, which, after being borne by Julius Cæsar, became the Crown Imperial. 3. The plain Circlet or Diadem. 4. The Obsidional Crown, given among the Romans to those who had performed exploits in the defence of fortified places. 5. The Civic Crown, for saving the life of a citizen. 6. The Crown Vallary, to soldiers who had first entered the enemy's trench. 7. The Mural Crown, to soldiers distinguished in besieging armies. 8. The Naval Crown, common in English coats of augmentation. 9. The Crown Celestial.

CROWN. In Architecture, the uppermost member of the cornice; called also *corona* and *larmier*.

CROWN or DEMESNE LANDS (*Terræ Dominicales*). The lands, estates, or other real property belonging to the crown or sovereign. These were anciently very extensive in this and most other European countries. The rents and other payments arising from them formed during the middle ages an important part of the revenue of our English kings; and they still form an important part of the revenue of several Continental sovereigns. These lands have been acquired by various means, such as purchase, succession, forfeiture, &c. Having been regarded for a lengthened period as the private property of the crown, and as being consequently at the free disposal of the sovereign for the time being, but little providence has been displayed in their management. A grant of crown lands was, indeed, the ordinary method in which our sovereigns used formerly to gratify their favourites; and, in consequence of the magnitude and improvidence of such grants, the crown estates in this country have been reduced within very narrow limits. Parliament frequently interposed to check this profusion, but without effect till after the Revolution, when the lavish grants of crown lands, made by William III. to the Bentinck and other families, occasioned so much dissatisfaction that the practice was put an end to. This was done by the act 1 Ann, st. 1. cap. 7., which declared that all future grants or leases of lands from the crown for a longer term than 31 years, and of houses for a longer term than 50 years, should be void.

The crown estates, forests, manorial rights, &c. not granted away, have now become, in consequence of arrangements to that effect, the property of the public; and are administered by a department specially appropriated to that purpose, called the "Woods and Forests." Their total nett revenue in 1838 amounted to 388,642*l*., collected at an expense of 10¾ per cent. Of late years a considerable extent of crown lands, consisting of old forests and chaces, have been enclosed and planted with forest trees, with a view to the supply of timber for the navy.

Certain lands, manorial rights, &c., with the sum paid as commutation for the loss of the tin duties, are the private property of the prince of Wales, as duke of Cornwall; and when there is no prince of Wales, of the crown.

CRU'CIBLE. (Lat. crucio, *I torment;* because, in the language of old chemistry, the metals were tortured by fire to yield up their various virtues.) A vessel, generally made of very refractory earthenware, in constant use in the chemical laboratory for performing fusions of metals and other substances.

CRUCI'FERÆ. (Lat. crux, *a cross;* the flowers being in the form of a Maltese cross.) A natural order of Exogens, inhabiting most temperate countries. They are allied to *Capparidaceæ*, but differ in their tetradynamous stamens; and also to *Papaveraceæ* and *Fumariaceæ*, but are distinguished by their seeds, and having no albumen. They are characterized essentially by their deviation from the ordinary symmetry observable in the relative arrangement of the parts of fructification of other plants. Linnæus divided this order into *Siliquosæ* and *Siliculosæ*, from the forms of their fruits; but more recently divisions have been founded upon the nature of the plicature of the cotyledons, and the position of the radicle with respect to them. They possess universally antiscorbutic and stimulant properties, combined with an acrid flavour; and their seeds uniformly abound in a fixed oil,—properties of which cress, mustard, and rape may be taken as representatives.

CRU'CIFIX. The figure of Christ upon a cross; also a cross with the figure of Christ upon it.

CRUDE. (Lat. crudus.) In Painting, a term applied to a picture when the colours are rudely laid on, and do not blend or harmonize.

CRUISE. (Germ. kreutzen, *to cross.*) A voyage within certain limits, for the purpose of meeting with enemy's ships, pirates, &c., or for mere exercise.

CRU'OR. (Lat. *gore.*) The red coagulum of the blood, which appears as the blood cools.

CRU'PPER. A roll of leather put under a horse's tail, and connected with the saddle by a strap and buckle, for the purpose of preventing the saddle from being cast forward on the horse's neck by the action of riding.

CRU'RAL. (Lat. crus, *the leg.*) Relating to the leg, or shaped like a leg or root.

CRUSA'DES. (Lat. crux, *cross.*) In the European History of the Middle Ages, wars undertaken by confederacies of chiefs and soldiers with a religious object. Those which were engaged in by great part of the nations of Europe for the recovery of Palestine from the infidels are more frequently denoted by this peculiar name. The term Crusade is derived from the sacred symbol of the cross, which was borne by the warriors engaged in it over their arms: the colour of the cross often served to designate the nation of the soldier; as, the white cross on a red ground, France; the red cross on a white

ground, England. The principal crusades for the conquest of Palestine were—1. The first, A. D. 1096, excited by the preaching of Peter the Hermit and the encouragement of Pope Urban II., in which Godfrey of Boulogne headed the Christians, who made themselves masters of Jerusalem and great part of Palestine. 2. The second, A. D. 1142, in which Conrad III. of Germany and Louis VII. of France led armies to complete the conquest of Palestine, but without success. 3. The third, A. D. 1189, was occasioned by the capture of Jerusalem by sultan Saladin; Frederic II. of Germany, Philip Augustus of France, and Richard Cœur de Lion of England were the chief among the confederate monarchs: the capture of Acre was almost the only fruit of this great expedition. 4. The fourth crusade was conducted by the King of Hungary, Andrew II., in 1217. 5. The fifth was conducted by Frederic II. of Germany (Barbarossa), who recovered Jerusalem, but for a short time. 6. The sixth, A.D. 1248, by Saint Louis king of France, against Egypt, but without success. Among other wars which have been at various times denoted by the name of Crusades, that against Raymond count of Toulouse and his heretical vassals the Albigeois, of which the first leader was the famous Simon de Montfort, is the most memorable. (*See* ALBIGENSES.) Whether the Crusades exercised a beneficial influence on the state and condition of society, is a question which has long engaged the attention of the learned; and, as is the case with every subject of a purely speculative character, different opinions have been entertained respecting it at different times. In the seventeenth century, when the question came first to be agitated, these extraordinary expeditions were generally regarded as having been in the highest degree favourable to the intellectual, commercial, and political interests of the world; but in the succeeding century there arose a host of inquirers, at the head of whom was Voltaire, less dazzled by the brilliancy which romance had thrown around these enterprises than the philosophers of the preceding age, by whom they were represented as mere ebullitions of superstition, fanaticism, and barbarism, which, how strongly soever they agitated the surface of society, in no degree contributed to its permanent improvement. And it was not until Robertson published the introduction to his *Charles V.*, in which he expressed his conviction that the Crusades had exercised a most favourable influence over the progress of freedom and the advancement of the human mind, that a check was given to these unfavourable views, and that the interest and importance formerly attached to the Crusades began to be revived. With the view of stimulating inquiry into this grand historical question, the French Institute, in the year 1806, with its usual enlightened spirit, proposed it to the learned of all countries as a subject of general competition; and the prize was awarded jointly to the essays of Heeren and Choiseul d'Aillecourt, which have since been published. These essays form the groundwork of the more elaborate researches of Michaud, and of the numerous other treatises upon this subject with which the literature of France, England, and Germany has since been inundated; and along with all the most recent discussions upon this question, which it has been our fortune to see, manifest a singular coincidence of opinion respecting the tendency of the Crusades, which, in spite of some strong drawbacks and disadvantages, they consider as having materially contributed to the revival of European learning and civilization. There are few disputed subjects of which it is more difficult to form a correct estimate than the influence of the Crusades, whether we regard the distant period when they took place, the insufficiency of contemporary history, the different phenomena and consequences by which they were accompanied in different countries, or, above all, the difficulty of assigning to these enterprises their own peculiar effects, amid the multiplicity of other causes, more powerful, perhaps, though less apparent, which were then operating on society. As our limits necessarily preclude us from entering upon this interesting inquiry, we must content ourselves with merely glancing at the chief arguments which have been adduced on both sides of the question. Some of those who maintain that the Crusades exercised a beneficial influence over the interests of society, scruple not to trace to them the origin of almost all the civilization which modern Europe at present enjoys. But those who take a more reasonable view of the matter, reckon among the advantages which resulted from these enterprises the general intercourse which they tended to establish between nations that might otherwise have long remained strangers to each other; the removal of international contentions and prejudices, which the union of nearly all the European states in pursuit of a common object tended to effect; the impulse which they gave to commercial enterprise throughout the world, more especially in Italy, and subsequently to the revival of literature and the fine arts in that country; the general diffusion of more liberal modes of thinking and acting on political and religious questions; and finally the breaking up of the feudal system, which, as is alleged, laid the foundation of the civil liberty at present enjoyed by all the communities of Europe. On the other hand, those who advocate the negative side of the question allege that the Crusades were begun in folly, prosecuted without skill, and ended in defeat. They caused, it is maintained, a waste of life and labour beyond example, without any advantageous return. For two centuries they afflicted almost every family in Europe with the most painful privations; and withdrew the attention of its inhabitants from the peaceful pursuits of industry to marauding expeditions undertaken in a spirit of religious fanaticism, and evincing in their conduct a disregard for the most obvious principles of justice. Agriculture, commerce, arts and education, were neglected by all ranks, under a general distemper of the imagination, which represented the recovery of the Holy Land from the possession of infidels as the most sacred and urgent of duties. In this Quixotic attempt, they sacrificed the flower of successive generations, and the strength and ornament of their respective countries. It is contended too by those who take this view of the matter, that the absence of the principal sovereigns from their kingdoms gave full scope to all sorts of faction and disturbance at home; and that though the power of some of the greater barons was broken by the debts and obligations they contracted during these expeditions, the anarchy inseparable from the feudal system was greatly augmented, and the progress of good government greatly retarded. Without attempting to determine the precise degree of weight that should be attached to these conflicting statements, it is abundantly clear that there has been, on both sides, a vast deal of exaggeration; and though it be obviously absurd to ascribe to the Crusades the superior wealth, civilization, and freedom of modern Europe, it is at the same time sufficiently clear that their beneficial influence, in various respects, countervailed to a considerable extent the impoverishment, anarchy, and war in which they involved the greater part of Europe and Asia. In addition to the prize essays already referred to, the reader may consult the elaborate and important work of *Michaud, l'Histoire des Croisades*, and his *Bibliographie des Croisades;* with *Wilken's Geschichte der Kreuzzüge; Haken's Gemälde der Kreuzzüge;* the art. "Croisades" in the *Encyclopédie des Gens du Monde*, &c. &c.

CRU'SCA, ACCADEMI'A DELLA. *See* ACADEMY.

CRU'STA. (Lat.) In Gem Sculpture, a gem engraved for inlaying on a vase or other object.

CRUSTA'CEANS, *Crustacea*. (Lat. crusta, *a hard covering*.) A class of free articulate animals, with articulated limbs, a branchial respiration, and a dorsal ventricle or heart.

CRY'OLITE. (Gr. κρυος, *ice*, λιθος, *stone*.) A rare mineral from Greenland. It is a double fluoride of sodium and aluminum. It readily fuses in the flame of a candle, whence its name.

CRYO'PHORUS. (Gr. κρυος, and φερω, *I bear*.) The frost-bearer or carrier of cold; an instrument contrived by Dr. Wollaston for freezing water by its own evaporation. (*Philos. Trans.* 1813, p. 71.)

CRYPT. (Gr. κρυπτω, *I hide*.) In Architecture, the under or hidden part of a building. It is used also to designate that part of the ancient churches and abbeys appropriated to the monuments of deceased persons. (See *Dugdale's Monasticon*.)

CRY'PTA. (Gr. κρυπτω.) In Botany, the round receptacles for secretion present in the leaves of some plants, as in the orange and myrtle.

CRY'PTÆ. (Gr. κρυπτω.) Little rounded excrescences, in which the minute ramifications of the arteries terminate in the cortical part of the kidneys.

CRYPTOGA'MIC PLANTS (Gr. κρυπτος, *concealed*, and γαμος, *marriage*), are those which never produce flowers or sexes, but which are multiplied without the aid of sexual intercourse. Linnæus gave them their name, upon the supposition that they in fact do possess sexual organs, although he was unable to discover them; and since his time Hedwig and others have endeavoured to show that sexes do exist in them, although in a concealed and anomalous state. In fact, it appears that in *Marchantianæ*, Mosses, *Jungermanniaceæ*, and some others, the reproductive organs are of two sorts, and it is not altogether unreasonable to call the one male and the other female; but at the same time it must be confessed that if such parts are rightly named, they are exceedingly dissimilar to the organs so called in Phanerogamic plants, and that the utmost which can be conceded to them is, that one contains a male principle and the other a female principle. From the recent observations of Agardh, Morren, Leveillé, Klotzsch, and others, it is not improbable that two such principles exist, although in a state of intimate intermixture, even in plants like *Fungi* and *Algæ*. The principal natural orders of Cryptogamic plants are *Ferns, Mosses, Equisetaceæ, Lycopodiaceæ, Characeæ, Hepaticæ, Lichens, Algæ*, and *Fungi*. In these orders we have the greatest variation in the organ of vegetation, some of the ferns forming trees 50 or 60

feet high, while many *Algæ* and *Fungi* are vesicular and microscopic. Among the latter, vegetable life approaches so nearly to that of animals that distinctions fail, and it is no longer possible to say that locomotion is the peculiar property of the one and fixation that of the other; for in numerous *Algæ* the seeds have an undoubted spontaneous power of motion in water until they begin their growth as young plants. Cryptogamic plants are connected with Gymnosperms through *Lycopodiaceæ* and *Equisetaceæ*, with Rhizanths through Fungi, and perhaps with Endogens by tree ferns; they do not appear to have any immediate relation to Exogens.

CRYPTO'GRAPHY. (Gr. κρυπτος, and γραφω, *I write.*) Also termed *Polygraphy* and *Steganography.* The art of writing in a manner intelligible only to those admitted into the secret of the method, either by conventional signs (cipher), or by other contrivances.

CRY'PTO PORTICUS. In Ancient Architecture, a concealed portico; also one that for coolness is enclosed on every side. Some of them were sunk some way into the ground.

CRY'STAL, *Crystallus.* (Gr. κρυσταλλος, *ice.*) This term was originally applied to those beautiful transparent varieties of silica, or quartz, known under the name of *rock crystal.* When substances pass from the fluid to the solid state, they frequently assume those regular forms which are generally termed crystals.

CRY'STALLINE LENS. The *lens* of the eye, placed in a depression upon the anterior part of the vitreous humour. *See* EYE.

CRY'STALLIZATION, *Crystallography.* (Gr. κρυσταλλος, *a crystal*, and γραφω, *I describe.*) The doctrine of the relation of crystalline forms, and of the origin and structure of crystals. Natural as well as artificial crystals occur in an infinite variety of forms; but they may generally be referred to some primary figure, of which these varieties may be regarded as modifications. The structure of crytallized bodies is most easily illustrated by reference to natural crystals, but the theory applies to all crystallized bodies; it assumes the existence of some definite primary figure, which by various truncations may be modified into its secondary forms.

The varieties of calcareous spar may be referred to as presenting one of the easiest illustrations of the mechanical texture of crystals, and of the modifications of which a definite primary figure is susceptible. Calcareous spar occurs in more than a hundred different forms, all of which, by careful mechanical division, are reducible to an *obtuse rhomboid*, whose faces are inclined to each other at angles of 105° 5′; this, therefore, is called the *primary form* of calcareous spar.

The *secondary forms* are presumed to be derived from the primary forms in consequence of *decrements* of particles taking place upon the edges, or angles, or both, of the primary form. Thus, if the primary form were a cube, it might be reduced to a secondary octahedron by decrements, or *truncations*, in the direction of the planes produced by the removal of its solid angles; and by a similar operation a primary octahedron might become a secondary cube.

The doctrine of the relations and conversions of these forms is, properly speaking, a branch of solid geometry; but its practical applications to chemistry have in fact rendered crystallography a subsidiary branch of those departments of science. By a careful examination of the forms and modifications and texture and fracture of crystals, the chemist and mineralogist are in many cases enabled to determine their nature or composition; and in some cases a strict examination of such forms may supersede analysis, or other more circuitous methods.

When we attempt by cautious mechanical means to dissect a crystal, we find that it will only yield kindly and afford smooth surfaces when broken or divided in certain directions. A *cube* of fluor spar, for instance, will only give way under such circumstances in the direction of its solid angles or corners; and pursuing the division in such directions an octahedron will be the resulting figure; and each slice which is removed may be further divided into octahedra and tetrahedra. The new and smooth surfaces resulting from this division or *cleavage* of the crystal are called its *cleavage planes*, the line produced by the meeting of two planes is called the *edge* of the crystal, and the meeting of any two lines or edges forms a *plane angle.* A *solid angle* is produced by the meeting of three or more plane angles. Different crystallographers have assumed various primitive forms as the bases of their respective *systems of crystallization.* Hauy assumed six (*Traité de Mineralogie*); Mr. Brooke enumerates fifteen primary forms (*Familiar Introduction to Crystallography*); and almost each author upon this subject has adopted different views as regard the number of fundamental forms and the modes of derivation of secondary figures. In Germany the system of crystallography of Mohs is pretty generally adopted. (See Haidenger's Translation of *Mohs' Mineralogy.*) But any detailed account of these different systems and theories would be inconsistent with our present object. It may be observed, however, that the *theory* of crystallization is greatly simplified by assuming all secondary forms as resulting from the aggregation of primary spherical or spheroidical molecules. (See a paper on this subject by Dr. Wollaston, in the *Philosophical Transactions for* 1813; and Mr. Daniell's interesting confirmations of the hypothesis in the first volume of the *Quarterly Journal of Science and the Arts.*)

The process of crystallization is resorted to for many useful and important purposes in the chemical arts: it is the principal means by which various saline products are obtained in a state of purity; for, in the act of crystallization, they throw off foreign substances and acquire definite composition. It is thus, for instance, that nitre is purified for the manufacture of gunpowder; and that the common and other salts with which crude nitre is contaminated are got rid of, a *crystal* of nitre being of necessity a definite compound of 54 parts of nitric acid combined with 48 of potassa. Nitre furnishes an instance of what is termed an *anhydrous* crystal; it retains none of the water in which it had been dissolved, and from which it is deposited. There are, however, many salts, the crystals of which are *hydrous;* and in such cases the quantity of water which they contain always bears a certain definite quantitative relation to the elements of the salts. Sulphate of magnesia, for instance, or Epsom salt, forms prismatic crystals, which always contain 51·2 per cent. of *water of crystallization:* they are constituted of 20 parts of magnesia, 40 of sulphuric acid, and 63 of water.

CTE'NOBRA'NCHIATA. (Gr. κτεις, *a comb*, and βραγχια, *gills.*) A name substituted by some naturalists for *Pectinibranchiata;* applied by Cuvier to that order of Gastropods which breathe by means of pectinated gills.

CTENOI'DES. (Gr. κτεις, and ειδος, *form.*) A name given by Agassiz to one of his orders of fishes, characterized by scales composed of layers with pectinated or toothed posterior margins. These combs overlapping one another give a rough feel to the skin: the scales are horny or bony, without enamel. The Ctenoid order includes the following families:—*Chetodontes*, *Pleuronectes*, *Percoides*, *Polyacanthes*, *Scienoides*, *Sparoides*, *Scorpenoides*, *Aulastomes.*

CU'BATURE, is the measurement of the contents of a solid body, or finding a cube equal to it.

CUBE. (Gr. κυβος, *a die.*) In Geometry, a solid body bounded by six equal squares. The cube is one of the five regular Platonic bodies, which, being placed beside each other, fill up the space about a point. It is also called the *hexaedron*, on account of its six sides. The *duplication* of the cube, or the finding of the side of a cube containing exactly twice as much matter as another given cube, was a celebrated problem among the geometers of antiquity, but which cannot be solved by means of the straight line and circle, the only lines which the ancients admitted into their geometrical constructions. (*See* DUPLICATION OF THE CUBE.) In arithmetic, *cubes*, or *cubic numbers*, are numbers formed by the multiplication of any number into itself twice: thus 8 and 27 are cubes; the first being equal to $2 \times 2 \times 2$, and the second to $3 \times 3 \times 3$.

CU'BEBS. The berries of the *Piper cubeba*, or *Java pepper.* They have a bitter and aromatic flavour, and contain volatile oil and resin: they are stomachic; and given in a dose of from one to two drachms in powder, two or three times a day, have proved curative in certain forms of *gonorrhœa.*

CU'BIC EQUA'TION. In Algebra, is an equation which involves the *cube* or third power of the unknown quantity. Like equations of any other degree, cubic equations are either *pure* or *adfected:* the pure containing only the cube of the unknown quantity; and the adfected containing the square or simple power, or both, of that quantity. A pure cubic equation is of this form, $x^3 = a$; where a is any number whatever, positive or negative, and the value of x is found by extracting the cube root of the number a by the usual arithmetical rule.

It might seem, at first sight, that the only value which x can have in the equation $x^3 = a$ is $x = \sqrt[3]{a}$; but on further consideration it will be seen that there are two more values of x, or at least two other sets of symbols by which the value of x may be represented, which equally satisfy the equation. On substituting n^3 for a, the equation becomes $x^3 = n^3$, or $x^3 - n^3 = o$; but $x^3 - n^3$ is resolvable into the two factors $(x - n) \times (x^2 + x\,n + n^2)$, therefore the equation is satisfied either by making $x - n = o$, or $x^2 + x\,n + n^2 = o$. The first gives $x = n$; and on solving the quadratic $x^2 + x\,n + n^2 = o$, the following values of x result, namely, $x = \frac{1}{2}(-n + \sqrt{-3\,n^2}) = \frac{1}{2}\,n\,(-1 + \sqrt{-3}$, and $x = \frac{1}{2}\,(-n - \sqrt{-3\,n^2}) = \frac{1}{2}\,n\,(-1 - \sqrt{-3})$. The three roots of the equation $x^3 - n^3 = o$ are therefore $x = n$, $x = \frac{1}{2}\,n\,(-1 + \sqrt{-3})$, $x = \frac{1}{2}\,n\,(-1 - \sqrt{-3})$; and this conclusion is easily verified by raising each of these three expressions to the cube, or by multiplying all three together: in either case the result will be n^3. It may be remarked that the first expression only for x is real, the two latter are imaginary,

A complete cubic equation has the form $x^3 + A\,x^2 + B\,x + C = o$, where A, B, and C denote known quantities, positive or negative. Now it is always possible, by assuming $x = y - \frac{1}{3} A$, to transform an equation of this form into another in which the second term shall be wanting, and which shall have the form $y^3 + a\,y + b = o$; the coefficients a and b of this last equation being also known, and depending on those of the former equation. If, therefore, we can succeed in finding the value or values of y from this equation, those of x will also become known in consequence of the equation $x = y - \frac{1}{3} A$.

In order to discover the roots of the equation $y^3 + a\,y + b = o$, suppose y to be composed of two parts, u and v, or assume $y = u + v$. The equation then becomes by substitution,

$$\left.\begin{array}{r} u^3 + 3\,u^2\,v + 3\,u\,v^2 + v^3 \\ + a\,u + a\,v \\ + b \end{array}\right\} = o;$$

which, as it contains two indeterminate quantities, may be divided into any two parts at pleasure. Let it be resolved into the two,

$$u^3 + v^3 + b = o,$$
$$3\,u^2\,v + 3\,u\,v^2 + a\,u + a\,v = o.$$

The last of these is the same as

$$(3\,u\,v + a)\;(u + v) = o,$$

which may be satisfied either by making $u + v = o$, or $3\,u\,v + a = o$. But the supposition that $u + v = o$ is inadmissible, since $u + v = y$; for if we suppose $y = o$, then on account of the original equation, $y^3 + a\,y + b = o$, it would be necessary to suppose also $b = o$, which is inconsistent with the hypothesis. To determine u and v, therefore, we have only the two equations,

$$u^3 + v^3 + b = o, \quad 3\,u\,v + a = o;$$

the first of which gives $u^3 + v^3 = -\,b$, and the second $u\,v = \frac{1}{3}\,a$, whence $u^3\;v^3 = \frac{1}{27}\,a^3$. On substituting in the first of these two last equations the value of v^3 deduced from the second, we find $u^3 + \frac{a^3}{27\,u^3} = -\,b$, from which u^3 is obtained by the solution of a quadratic. The solution gives $u^3 = -\frac{1}{2}\,b \pm \sqrt{\frac{1}{27}\,a^3 + \frac{1}{4}\,b^2}$; whence, and from the equation $u^3 + v^3 = -\,b$, $u^3 = -\frac{1}{2} b + \sqrt{\frac{1}{27} a^3 + \frac{1}{4} b^2}$, $v^3 = -\frac{1}{2}\,b - \sqrt{\frac{1}{27}\,a^3 + \frac{1}{4}\,b^2}$, $u = \sqrt[3]{-\frac{1}{2} b + \sqrt{\frac{1}{27} a^3 + \frac{1}{4} b^2}}$, $v = \sqrt[3]{-\frac{1}{2}\,b - \sqrt{\frac{1}{27}\,a^3 + \frac{1}{4}\,b^2}}$; but $y = u + v$, therefore

$$y = \sqrt[3]{-\tfrac{1}{2} b + \sqrt{\tfrac{1}{27} a^3 + \tfrac{1}{4} b^2}} + \sqrt[3]{-\tfrac{1}{2} b - \sqrt{\tfrac{1}{27} a^3 + \tfrac{1}{4} b^2}}.$$

Having obtained a value of y in terms of a and b, which satisfies the equation $y^3 + a\,y + b = o$, that equation is resolved; but, as in the case of pure cubic equations, two other values of y may be found, each of which also satisfies the equation. For the sake of abridging, let $P = -\frac{1}{2}\,b + \sqrt{\frac{1}{27}\,a^3 + \frac{1}{4}\,b^2}$, $Q = -\frac{1}{2}\,b - \sqrt{\frac{1}{27}\,a^3 + \frac{1}{4}\,b^2}$; and let also $p = \frac{1}{2}\,(-1 + \sqrt{-3})$, $q = \frac{1}{2}\,(-1 - \sqrt{-3})$; then $u^3 = P$, and $v^3 = Q$; and in consequence of what was shown above u and v have each these three values:

$$u = \sqrt[3]{P}, \quad u = p\,\sqrt[3]{P}, \quad u = q\,\sqrt[3]{P}, \qquad (m)$$
$$v = \sqrt[3]{Q}, \quad v = p\,\sqrt[3]{Q}, \quad v = q\,\sqrt[3]{Q}. \qquad (n)$$

To determine in what manner these equations must be combined in order to give the corresponding values of y $(= u + v)$, we must recollect that $u\,v = \frac{1}{3}\,a$; but $P\,Q = \frac{1}{27}\,a^3$, or $\sqrt[3]{P\,Q} = \frac{1}{3}\,a$; therefore $u\,v = \sqrt[3]{P\,Q}$. But it is obvious that $p\,q = 1$; in order therefore to preserve these relations, we must combine the first of the equations (m) with the first of (n), the second of (m) with the third of (n), and the third of (m) with the second of (n). Hence the three values of $u + v$, or y, are $y = \sqrt[3]{P} + \sqrt[3]{Q}$, $y = p\,\sqrt[3]{P} + q\,\sqrt[3]{Q}$, $y = q\,\sqrt[3]{P} + p\,\sqrt[3]{Q}$.

The first of these three formulæ was invented by Nicholas Tartalea and Scipio Ferreus independently about the same time; but having been first published by Cardan, is generally known by the name of *Cardan's Rule*.

In applying the above formula for the resolution of a cubic equation, it is necessary to extract the square root of the quantity $\frac{1}{27}\,a^3 + \frac{1}{4}\,b^2$. Now, as a and b may have any values whatever, if it happen that a is negative, and such that $\frac{1}{27}\,a^3$ is greater than $\frac{1}{4}\,b^2$, the quantity $\frac{1}{27}\,a^3 + \frac{1}{4}\,b^2$ becomes negative, and the extraction of its square root impossible. This circumstance gives rise to what is termed the *irreducible case*, and long continued to puzzle algebraists, the three roots of the equation appearing all under an imaginary form. It has been found, however, from a more profound analysis of the nature of equations, that in this case (that is, when a is negative, and $\frac{1}{27}\,a^3$ greater than $\frac{1}{4}\,b^2$) all the three roots are real, notwithstanding their imaginary form. In fact, every equation of the third degree must have at least *one* real root: when the irreducible case occurs, *all* the roots are real; in the other case, one root is real, and the other two imaginary.

CUBI'CULUM. (Lat.) In Ancient Architecture, strictly a bed room; but with the Romans applied in a more extended sense to the balcon or tent provided to cover the emperors at the public shows.

CU'BIT. (Lat. cubitus.) In Architecture and Sculpture, a linear measure of the ancients, equal to the length of the arm from the elbow to the extremity of the middle finger, usually considered about eighteen English inches. The geometrical cubit of Vitruvius was equal to six ordinary cubits.

CU'BITUS. The fore arm; the larger bone of which is called the *os cubiti*. This term is said to be derived from cubo, *I lie down*, from the ancient custom of leaning on that part of the arm when in the recumbent posture at meals.

CU'CULINÆ. A name given by Latreille to a family of bees, distinguished by the absence of the femoral plates for transporting pollen, and which are consequently compelled to resort to the combs of other bees in order to deposit their eggs: hence they may be regarded, like the cuckoo, as a kind of parasite.

CU'CULUS. (Lat. cuculus, *a cuckoo*.) A most interesting genus of Passerine birds, belonging to that group which is characterized by having the toes situated two before and two behind (*Zygodactyli*); and so named from including as the typical species the common European cuckoo (*Cuculus canorus*). The cuckoo is a migratory bird; it arrives in England in the month of April for the purpose of breeding. It differs from almost every other bird in not constructing a nest, nor under any circumstances hatching its own eggs; but deposits them in the nests of other birds, as the hedge-sparrow. The unfledged young have a remarkable instinct, which impels them to unceasing efforts to expel their helpless companions from the nest, which they effect by pushing them in the hollow of their back to the verge of the nest, and tilting them over, until they at length monopolize all the care and provision of the foster-parent. The young cuckoos of the year do not leave this country till the month of September.

CUCU'RBITA'CEÆ. (Cucurbita, one of the genera.) A natural order of Exogens, inhabiting the hot countries of both hemispheres. They are placed by Auguste de St. Hilaire and De Candolle between *Myrtaceæ*, to which they appear to have little affinity, and *Passifloraceæ*, to which they are so closely allied that they differ only in the sinuous stamens, unisexual flowers, inferior fruit, and exalbuminous seeds. St. Hilaire also insists upon their affinity with *Onagraceæ*, with which, including *Combretaceæ*, they agree in some respects. The order is one of the most useful in the vegetable kingdom, comprehending the melon, the choco, and the various species of gourd; all valuable as the food of man. Colocynth is the pulp of *Cucumis colocynthis*, which is so drastic as to be classed by Orfila among his poisons. The root of *Bryonia* possesses a powerful purgative property, but is said to become wholesome if properly cooked; and the perennial roots of all the order appear to contain similar bitter drastic virtues: especially of the *Momordica elaterium*, which has an active poisonous principle called *elatine*.

CUIRA'SS. (Fr. cuir, *leather*.) A covering for the breast; originally, as the name denotes, of leather, also of quilted linen, cloth, &c. The cuirass of plate-armour succeeded the hauberk, hacqueton, &c. of mail, about the reign of Edward III.; and from that period the surcoat, jupon, &c., which were usually worn over the coat of mail, began to be laid aside. From that period the cuirass or breast-plate continued to be worn, and was the last piece of defensive armour laid aside in actual warfare. There were cuirassiers in the English civil wars, and in the French service nearly to the end of the 17th century: after this period, the cuirass was generally laid aside, until it was again employed by some of Napoleon's regiments, and it is now, in most services, worn by some regiments of heavy cavalry.

CUISSES, CUISSOTS, CUISSARTS, &c. In Plate Armour, the pieces which protected the front of the thigh.

CULDE'ES. A religious order, whose origin is attributed to St. Columba, an Irish monk of the 6th century, who evangelized the western parts of Scotland, and founded a famed monastery in Iona. The word is probably contracted from *cultores Dei*. See *Jamieson's Hist.*

CU'LEX. (Lat. *a gnat*.) A Linnæan genus of insects, having the common gnat (*Culex pipiens*, L.) for its type; but now raised to the rank of a family (*Culicidæ*), including the genera *Megarhina, Sabethes, Œdes, Aropheles*, and *Culex* proper: the two latter are British.

CU'LINARY VEGETABLES. Plants cultivated in gardens, and sometimes in fields, for culinary purposes. They may be classed as—leaf plants, such as the cabbage tribe, spinaceous plants, salads, pot and sweet herbs; stalk plants, such as asparagus, tart rhubarb, sea kale, &c.; roots, such as the turnip, carrot, potato, &c.; seeds, such as the pea and bean; fruit, such as the cucumber, gourd, &c.; and the entire plants, such as the onion, leek, mushroom, &c. They may be otherwise arranged as—the

cabbage family; the leguminous family; esculent roots; spinaceous plants; aliaceous plants; asparaginous plants; acetarious plants; pot herbs, sweet herbs, plants used in tarts and confectionary, and edible fungi.

CULI'NUS. A term introduced by Linnæus to denote the stem of *Graminaceæ*, which has a peculiar organization. The term is now used by few writers.

CU'LLET. The term given to broken glass brought to the glass house for the purpose of being melted up with fresh materials.

CULM. A provincial synonym of *anthracite*. Mineral carbon, glance coal, columnar coal, are terms also applied to this species of coal, of which Kilkenny coal furnishes an example.

CULM. In Agriculture, the stem of grasses.

CULMINA'TION. (Lat. culmen, *the top*.) The passage of a celestial body over the meridian, or the highest point of its diurnal circle.

CULTIVA'TOR. An implement of the horse-hoe kind, chiefly used in working fallows. It consists of a frame, sometimes of wood and sometimes of iron, into which a number of coulters, or tines, are introduced; which, when the instrument is drawn along lands already ploughed, penetrate to the bottom of the furrow, and thoroughly pulverize the soil. One of the best of these implements for using on a large scale is Finlayson's harrow; but it requires six horses to work it properly. On a small scale, and for working with two horses between rows of plants, Wilkie's grubber is an excellent implement; as is that known as Kirkwood's cultivator.

CU'LTRATE. (Lat. culter, *a ploughshare*.) Coulter-shaped, as when a body is straight on one side and curved on the other.

CU'LVERT. An arched channel of masonry built beneath the bed of a canal, for the purpose of conducting water under the canal. If the water to be conveyed has nearly the same level as the canal, the culvert is built in the form of an inverted siphon, and acts on the principle of a water pipe. This word also signifies any arched channel for water under ground.

CU'LVERIN. A cannon equal to an 18-pounder; a *demy-culverin* is a 9-pounder.

CU'MIN SEED. The seed or fruit of the *Cuminum cyminum*. It is imported from Sicily and Malta. It forms an ingredient in *curry powder*, and in some kinds of cheese; it has also been used medicinally, but is unimportant. It has a very peculiar odour, and a bitter and aromatic taste. In poultices and plaisters, it is supposed to promote the dispersion of indolent tumours. Some of the Roman poets allude to its power of producing pallor and languor.

CU'NEATE. (Lat. cuneus, *a wedge*.) An animal or part is so called which has the longitudinal diameter exceeding the transverse, and narrowing gradually downwards.

CU'NEIFORM LETTERS, called *Keilschriften* by the Germans. (Lat. cuneus, *a wedge*.) The name given to the inscriptions found on old Babylonian and Persian monuments, from the characters being formed like a wedge. This species of writing, as it is the simplest, so it is the most ancient of which we have any knowledge; and though it is difficult to say by whom or in what country it was invented, its use was common to the Medes, Persians, and Assyrians, at the most remote periods of their history. It should seem, however, that the peculiarity of its form caused it to be employed, like the hieratic character of the Egyptians, chiefly in monumental inscriptions, there being another mode of writing in use better calculated for ordinary purposes; and Mr. Rich conjectures that it fell into disuse soon after Alexander's conquest of Persia, when neither the Persians nor the Babylonians had any monuments to erect or events to record. The native princes, says that ingenious traveller, who wrested the throne of Persia from his feeble successors, adopted the Greek language and character in their coins and inscriptions; and all recollection of the cuneiform writing must have perished during the long period in which they held the sceptre of Iran.

About seventy years ago, a few specimens of inscriptions existing at Persepolis having found their way into Europe, the attention of the learned was directed to the subject; and many German philologists, at the head of whom was the celebrated Tychsen, applied themselves to the task of deciphering and translating these inscriptions with an unrivalled energy and enthusiasm. It was not, however, till the commencement of the present century, when Dr. Grotefend of Hanover engaged in the pursuit, that the mystery in which this species of writing had for so many centuries been involved began to be cleared up, and the foundation laid of a more satisfactory and philosophical mode of explication. As might be expected on a subject on which so much wing may be given to the imagination, the most diverse and extraordinary theories have been propounded respecting it, many of them supported by ingenious reasonings, and displaying great learning and research; but as the general opinion inclines to regard Dr. Grotefend's theory as based on the most solid foundation, and as the most likely to lead to important results, we shall limit ourselves to giving a brief summary of his views. According to him this mode of writing is formed of two radical signs,—the wedge and the angle,—susceptible, however, of about thirty different combinations; and consists of three varieties, distinguished from each other by a greater or less complication of the characters. It is of Asiatic origin; is written from right to left, like the Sanscrit; differs from the ancient Egyptian hieroglyphics, inasmuch as it is alphabetic, not ideographic; and, finally, with a few considerable modifications, forms the basis of most of the Eastern languages. The views of Dr. Grotefend received striking confirmation from the researches of Mr. Rich, whose valuable Memoirs, enriched at they are with numerous inscriptions found at Babylon and Persepolis, cannot fail to give considerable impulse to the prosecution of this intricate study. A full exposition of this species of writing would prove one of the most valuable accessions to modern literature, as it would throw a flood of light upon many points of the manners, customs, and civil polity of many Eastern nations now enveloped in the most profound obscurity, and rescue their ancient history from the gross fictions by which it is disfigured in the modern literature of Persia. But upon this subject we are far from entertaining very sanguine hopes. Apart from the collateral benefits which have flowed from the prosecution of this study, and which have exhibited themselves chiefly in the greatly increased desire that exists throughout Europe to obtain a knowledge of the Eastern languages, the only direct results by which it has been hitherto followed may be stated to be the translation of a few minor inscriptions, and the establishment of a canon so extremely arbitrary, that it is very problematical if the labours of others in the same field can be materially benefited by it. To all who have read the paper of Dr. Grotefend addressed to the university of Göttingen two years ago, in which all that has been done on this subject is exhibited with much perspicuity, it must be matter of painful regret to observe that the immense amount of labour and learning expended upon it has been attended by such incommensurate results; and a study which has proved so unproductive even to its most enthusiastic disciple will scarcely be found to improve in the hands of others, who, whatever be their qualifications, can never be expected to surpass the gentleman in question either in learning, ingenuity, or devotion to the subject. For further information on this subject, the reader is referred to *Rich's Memoirs*, which contain innumerable specimens of the cuneiform writing.

CU'NONIA'CEÆ. (Cunonia, one of the genera.) A natural order of arborescent or shrubby Exogens, inhabiting South America and the East Indies; allied so very intimately to *Saxifragaceæ*, that they are only distinguished by their arborescent habit and interpetiolar stipules. The bark of some species is used for tanning leather.

CU'PEL. A shallow earthen vessel, somewhat of a *cup* shape, generally made of bone earth. It is used in the assays of the precious metals, which are fused upon a cupel with lead. Cupellation means the refining of gold or silver upon a *cupel*.

CU'PID. (Lat. Cupido.) The Roman name of the Grecian god of love Eros (Ἔρως). There were three divinities, or rather three forms of the same deity, with this appellation (*Cic. de Nat. Deor.* 3. 23.); but the one usually meant when spoken of without any qualification was the son of Mercury and Venus. Like the rest of the gods, Cupid assumed different shapes; but he is generally represented as a beautiful child with wings, blind, and carrying a bow and quiver of arrows, with which he transpierced the hearts of lovers, inflaming them with desire. Among the ancients he was worshipped with the same solemnity as his mother Venus; his influence pervaded all creation, animate and inanimate; and vows and sacrifices were daily offered up at his shrine. Statues of Cupid formed among the ancients great objects of *vertu*. Praxiteles is said to have derived great honour from his statues of this divinity; and in his orations against Verres, Cicero has given celebrity to one statue of Cupid by this artist, which formed an object of peculiar veneration to the Thespians.

CU'POLA. (It.) In Architecture. *See* DOME.

CU'PPING. (From the *cup shape* of the glasses used in its performance.) In this operation a cup-shaped glass is used, into which the large flame of a spirit lamp is momentarily introduced, so as to expel a great part of its air by dilatation; it is then instantly applied to some part of the body, which is forced into it by the external pressure; and on removing the glass a circular red mark is left, from the propulsion of the blood in the small vessels of the part: this is called *dry cupping*. It is generally followed up by making a number of incisions in the part by means of an instrument called a *scarificator*, from which the blood oozes, and from which a considerable portion may be drawn by again applying the cupping glass. Cupping, when well performed, is not a very painful or disagreeable operation, and is an excellent mode of local

blood-letting. When the operator is not dexterous, it is not only painful, but often dangerous in its consequences. The bleeding may generally be easily stopped by a piece of lint or soft rag; but this should be looked after, as instances have occurred of persons bleeding to death from the wounds of a scarificator.

CUPULI'FERÆ. (Lat. cupa, *a cup.*) A natural order of arborescent or shrubby Exogenous plants, inhabiting all temperate and some hot climates. They are distinguished by their amentaceous flowers and peculiarly veined leaves from all European trees; and from other plants by their apetalous superior rudimentary calyx, fruit enclosed in a husk or cup; and by their nuts, which contain but one cell and one or two seeds, in consequence of the abortion of the remainder. These plants are akin to *Betulaceæ* and *Salicaceæ*, from which they are distinguished by the presence of a calyx and the veining of the leaves. They are nearly allied to *Urticaceæ;* but differ in their many-celled ovary, pendulous ovules, and superior calyx. This order comprehends the oak, hazel, beech, chestnut, and hornbeam,—well known valuable forest trees.

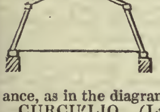
CURACO'A. A liqueur which derives its name from the island of Curacoa: it is prepared in great perfection by the Dutch. It derives its flavour from Seville orange peel, with a small quantity of cinnamon and mace.

CURASSOW. *See* CRAX.

CU'RATE. (Lat. curare, *to take care.*) Properly an incumbent who has the cure of souls; now generally restricted to signify the spiritual assistant of a rector or vicar in his cure. Curates form the lowest order of the clergy; and are divided into two classes, perpetual and stipendiary. "Perpetual curates are such as are appointed to the churches of those parishes in which the tithes were appropriated to some monastery before the statue 4 H. 4. making it necessary to endow a vicar, or which had from some cause or other escaped its operation;" or they are such as officiate in some chapel: in either of which cases, their salary is usually paid by some fixed payment, or by a portion of the tithes appropriated for their maintenance at the foundation of the chapel. Stipendiary curates are such as are appointed by the vicar or rector to officiate at their churches in their stead. The salary of stipendiary curates is defrayed by the party who appoints them; and by the 57 Geo. 3. c. 90. it must in no case be under 90*l.*; and where the population of the parish amounts to 500, with certain restrictions, 150*l.* (See *M'Culloch's Stat. Brit. Empire*, vol. ii. 280. 2d ed.)

CURA'TOR (Lat.), in a general sense, signifies a person who is appointed to take care of any thing. Among the ancient Romans, there were officers in every branch of the public service to whom this appellation was given: thus we read of *Curatores frumenti, viarum, operum publicorum, Tiberis*, &c. &c.; *i. e.* persons who distributed corn, superintended the making of roads and the public buildings, or were conservators of the river. — Curator, in the Civil Law, is the guardian of a minor who has attained the age of fourteen. Before that age, minors are under a tutor. The guardianship of persons under various disabilities, and of the estate of deceased or absent persons and insolvents, is also committed to a *curator*. This title is derived from the ancient Romans, by whom, as was remarked above, it was given to various officers who acted as superintendents of different departments of the public service. In learned institutions, the officer who has charge of libraries, collections of natural history, &c. is frequently styled curator.

CURB ROOF. (Fr. courber, *to bend.*) In Architecture, a roof in which the rafters, instead of continuing straight down from the ridge to the walls, are at a given height received on plates, which in their turn are supported by rafters less inclined to the horizon, whose bearing is, through the medium of the wall-plate, directly on the walls. It presents a bent appearance, as in the diagram, whence it derives its name.



CURCU'LIO. (Lat. curculio, *a weevil.*) A Linnæan genus of Coleopterous insects, now the type of an extensive family, — *Curculionidæ*, or weevils belonging to the Tetramerous section of the order. The prolongation of the anterior part of the head, in the form of a proboscis or snout, at once distinguishes the insects of the present family from all other beetles. The number of the *Curculionidæ* may be imagined when it is stated that entomologists have found it necessary to distribute them into nearly three hundred subgenera. They are all vegetable feeders, and include some of the most dangerous enemies to the vegetable stores of mankind.

CU'RFEW. (From the French couvre-feu, in modern Latin ignitegium.) The practice of tolling the church bell at eight or some other hour in the evening, to warn people to extinguish their fires, was a very common one in the middle ages. It is difficult to say on what foundation the common tradition, that William the Conqueror introduced it from Normandy to prevent the English from assembling in the evening to plan schemes of rebellion, rests. Lord Lyttleton, in his *Life of Henry II.*, discusses the question. It is more probable that the Conqueror enforced a very common police regulation. The real reason of the curfew was to prevent fires. The custom of ringing the evening or curfew bell is still retained in many places. (See *Brand's Popular Antiquities*, vol. ii. p. 136, 137.)

CU'RIA. (Lat.) In Ancient Architecture, a court, council, or senate house.

CU'RIES, *Curiæ*. A subdivision of the Roman patrician tribes, each of which were divided into ten *curies*. Three *curies* probably contained originally ten houses (*gentes*) each. These houses were similar to the Scottish clans, in which, though the bond of union was supposed to be that of common blood, yet in reality there was no consanguinity between many of the component families.

CURL. A disease in potatoes, in which the leaves on their first appearance appear curled and shrunk up; and consequently, as they do not present a sufficient surface to the light to elaborate the sap in a sufficient manner for carrying on the growth of the plant, it never acquires strength, and either dies, or produces very imperfect tubers. The cause of the disease in the first instance is generally supposed to be the unhealthy state of the set; but something also may be owing to bad management and improper soil.

CU'RRANT. The fruit of two species of *Ribes;* namely, *R. rubrum*, which furnishes the common red and white currants; and the *R. nigrum*, which produces the black currant. The currants of the grocers' shops are the dried berries of a small species of grape cultivated in Zante, Cephalonia, and Ithaca; and in the Morea in the vicinity of Patras. Notwithstanding the heavy duty of 22*s.* 2*d.* per cwt. with which this commodity is burdened, they are largely imported into the British empire, The entries of currants for home consumption amounted at an average of the two years ending 1838 to 193,827 cwt., producing an annual revenue of 189,192½*l.*

CU'RRENCY. (Lat. curro, *I run.*) In Political Economy, a term sometimes used to express the collective amount of the money, and of the bills, cheques, and other substitutes for money, employed in selling or buying, or in the distribution of commodities and services among the different ranks and orders of the community.

CU'RRENT (Lat. curro.), denotes in its most general sense the progressive movement of any object; but it is applied chiefly to the progressive movement of fluids, especially of air, electricity, and water.

Currents in the ocean arise from various causes, either occasional or constant. They may be occasioned by an external impulsion, for example a gale of wind; from a difference in the temperature of different parts of the sea; from the inequality of evaporation, the melting of the polar ice, or in short any cause tending to disturb the hydrostatic equilibrium. It is difficult in many cases to trace their causes, or to give any satisfactory theory of their existence; but on account of their importance to navigation they have been observed, especially of late years, with great care. Among those which have a permanent or general character, there are two which are very remarkable. The first is that of the tropical waters westward round the globe, and the second that which constantly flows from each pole towards the equator. The tropical or westerly current is chiefly confined within the zone extending to about 30° on each side of the equator, and its velocity is estimated by Humboldt at about nine or ten miles a day. In the Atlantic it separates into two branches: one of which forms the *gulf stream;* and the other flows along the coast of Brazil, and passes through the Straits of Magellan. The gulf stream flows northward through the middle of the Atlantic, till it reaches the Cape Verd Islands; it then passes through the Caribbean Sea, between Cuba and the peninsula of Yucatan, sweeps round the Gulf of Mexico, and rushes out by the Bahama Channel; then, spreading out to a greater breadth, it continues its course along the shores of the United States to Newfoundland, where it is deflected eastward by a current setting in from Baffin's Bay; and, passing the Azores and Canary Islands, returns in a great measure into itself. Its breadth is 51 leagues in the Bahama Channel, and velocity from 3 to 5 miles an hour. (*Murray's Geography*, p. 186.) The polar currents flow constantly from the poles towards the equator, though it is evident that their sources must be supplied by currents in a contrary direction. Their existence is proved by the great masses of ice which are carried every year from the polar seas to tropical latitudes. Oceanic currents, by carrying with them the temperature of the regions whence they flow, contribute in no small degree to modify the temperature of the atmosphere, and give a character to the climate of the countries to which they are contiguous. On the parallel of New York Humboldt found the temperature of the gulf stream 72° of Fahrenheit, while out of the current the heat of the ocean at the surface was only 63°. The current which flows

along the eastern coast of Africa, and doubles the Cape of Good Hope in a stream 130 miles broad, is from 7° to 8° warmer than the contiguous sea. The existence of *under currents* in the ocean is suspected rather than proved. For currents in the atmosphere, *see* WINDS.

CU'RRYING. (Fr. corroyer.) The art of dressing skins after they are tanned, for the purposes of the shoemaker, saddler, and harness-maker, &c.; or of giving them the necessary smoothness, lustre, colour, and suppleness. The operation of currying is performed in two ways; either upon the flesh, or on the hair, or, as it is technically called, the *grain;* and consists chiefly of four processes, which require great experience and dexterity. The reader will find in Dr. Ure's *Dictionary of Arts, &c.* a full account of this curious operation, accompanied by a wood cut illustrative of the singular tools and manipulations which it requires.

CU'RSITORS. (Lat. curro, *I run.*) Officers in the Court of Chancery, whose duty it is to make out original writs. They are called also clerks of the course (clerici de cursu); and are 24 in number, forming a peculiar corporation. Cursitor Baron is the name of an officer in the Court of Exchequer, who administers the oath to all high sheriffs, under sheriffs, bailiffs, and all the functionaries of the customs.

CURTAI'L STEP. (Lat. curtus, *short.*) The lower step in a flight of stairs ending at its outer extremity in a scroll. Perhaps taking its name from the step curling round like a cur's tail.

CURTA'NA. The sword (as it is called) of Edward the Confessor, which has its edge blunted as an emblem of Mercy. It is carried between the swords of justice temporal and justice spiritual; and borne before the kings of England at their coronation.

CU'RTATE DISTANCE. A term employed in astronomy to denote a planet's distance from the sun reduced to the plane of the ecliptic. The curtate (or shortened) distance is therefore equal to the true distance multiplied by the cosine of the planet's heliocentric latitude.

CU'RTESY or COURTESY OF ENGLAND, in Law, is the right of a husband who has married a wife seised in fee simple or fee tail general, or heiress in special tail, and has issue male or female born alive, and which by possibility may inherit, to hold her lands after her death for his life. (*See* MARRIAGE, LAW OF.) Thus, four things are said to be necessary to give an estate by the curtesy, — marriage, seisin of the wife, issue, and death of the wife.

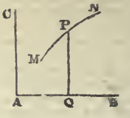
CU'RULE MAGISTRACIES, in Ancient History, were those of the greatest dignity in the Roman state; and were distinguished from all others by the privilege enjoyed by the persons who held them of sitting on ivory chairs (*sellæ curules*) when engaged in their public functions. The curule magistrates were the consuls, prætors, censors, and chief ædiles; which last, on account of this privilege, were called curule ædiles, to distinguish them from the plebeian.

CU'RVATURE. The continual flexure or bending of a line from the rectilinear direction. The curvature of a circle is greater in proportion as the radius is smaller; and the curvature of any other curve at a given point is measured by comparing it with a circle which *osculates* it, or forms with it a contact of a particular kind at that point. (*See* OSCULATING CIRCLE, and RADIUS OF CURVATURE.) The determination of the curvature of curve lines requires the aid of the differential calculus.

CURVE. In Analytical Geometry, a line of which no three consecutive points are in the same direction or straight line. The general theory of curve lines, and of the figures bounded by them, forms an extensive and important part of mathematical science, and in fact properly constitutes what is called the high or transcendent geometry. It will easily be understood, however, that the curves which form the object of geometrical speculation are those only of which the succession of points observes a regular law, capable of being expressed by a mathematical formula; not those which are formed irregularly by the hand, for example, like letters in writing.

Although the ancient geometricians had bestowed some attention on the subject of curve lines, and in addition to the conic sections had investigated some of the properties of a few other curves, as the cissoid, the conchoid, particular kinds of spirals, and perhaps others whose names may have been forgotten; yet their researches had only led them to the knowledge of a small number of particular propositions deduced from a laborious consideration of the circumstances of each individual case, and not admitting of extended application. The general methods of investigation which the modern geometer can apply with so much greater advantage are owing to the progress of algebra, and the happy invention by Descartes of the method of defining curves by algebraic equations.

Let M N be a curve, and A B, A C two straight lines in the same plane, to which all its points are referred; then A B and A C are the axes of the curve. Take a point P in the curve, and draw P Q parallel to A C; the line A Q is called the absciss of the point P, and is denoted by x; and P Q the ordinate, and denoted by y.



Now if for any given value of A Q a corresponding value of P Q can be assigned, that is, if P Q can be expressed in terms of A Q and known quantities, that expression is called the equation of the curve, and all its properties can be thence deduced by means of algebraic transformations without any reference to the diagram.

The first use of this method of defining curve lines by means of an equation between the absciss and ordinate is to enable us to divide them into classes, of which all the individuals have some properties in common. Descartes divided them into two great classes, — *geometrical* and *mechanical.* It is now usual to indicate the same distinctions by the terms *algebraic* and *transcendental.* Algebraic curves are those in which the relation between the absciss and the ordinate is expressed by an algebraic equation: transcendental curves are those in which the relation between x and y is not expressed by an algebraic, but by a differential equation; that is, by an equation between dx and dy. There is still a class which may be regarded as intermediate between these two; namely, *exponential* curves, or those in the equation of which one or both of the unknown quantities enters as an exponent. Such, for example, is the equation $y = a^x$.

In order to form an idea of a curve of which the equation is given, it is necessary to suppose the equation resolved; that is to say, that the value of y is found in terms of x and given numbers. This being found, we take all the positive values of x from 0 to + infinity, and also all the negative values to − infinity. The corresponding ordinates or values of y will give all the points of the curve; the positive ordinates being taken on one side of the axis of the abscissa, and the negative on the opposite side.

Algebraic curves are divided into different classes or orders, according to the degree of the equation which expresses the relation between their co-ordinates. Straight lines are denominated lines of the *first order,* because the equation of a straight line being of the form $0 = A + Bx + Cy$, is only of one dimension; that is to say, it contains no powers or products of the variables x and y. Lines of the second order are those of which the equation rises to two dimensions. The general form of this equation is,

$$0 = A + Bx + Cy + Dx^2 + Exy + Fy^2;$$

and the curves which it includes are the conic sections; that is, the circle, the ellipse, the hyperbola, and the parabola. These curve lines are the simplest of all, because lines of the first order are not curves; hence they are sometimes called *curves of the first order.* Following out the analogy, lines of the *third,* or those whose equation rises to the third degree, are *curves of the second order,* and so on.

The dimension of the equation of a curve line is not altered by changing the origin or position of its co-ordinates, or in making any transformation of its axes. It follows, therefore, that a line of the nth order can never be intersected by a straight line in more than n points, because the ordinates can never have more than n real values. This follows from the general theory of equations; and in fact all the properties of any curve line being deducible from its equation, a complete theory of algebraic equations of any degree includes the theory of lines of that order. In this way it is proved that all lines of any order of which the number is uneven have necessarily at least two infinite branches; for in this case one at least of the co-ordinates is raised to an uneven power in the equation — for example, the 3d, the 5th, &c.; and therefore will have at least one real value, whatever value (which may be increased *in infinitum,* positively and negatively) may be given to the other co-ordinate.

We have mentioned that the lines of the second order include only the circle and the conic sections. Newton, in his *Enumeratio Linearum Tertii Ordinis,* reckons 72 *species* of lines of the third order, or curves of the 2d degree. As the order is more elevated the number of *genera* and species becomes more numerous. The subdivisions into genera and species are, however, founded on some arbitrary properties, and consequently are not made uniformly by different authors. Cramer, in his *Analyse des Lignes Courbes,* found fourteen different genera of curves of the third order; and Euler (*Introductio in Analysin Infinitorum*) sixteen. The whole number of curves belonging to this order has been supposed to amount to some thousands.

Curves of Double Curvature.—Hitherto we have spoken only of curves on a plane; but if they are traced on surfaces which are not plane, they will have a double curvature; that which belongs to the line itself, and that of the surface on which it is traced. In order to investigate the properties of a curve of this sort, it must be supposed to be projected on two different planes perpendicular to each other; the projections will be two ordinary curves having a common axis and different ordinates. One of these curves will be defined by an equation between x and y, and the other by an equation between x and z; so that the

equation of a curve of double curvature is composed of two equations, each containing two variables, of which one is common to both equations, and taken on the line of intersection of the two planes of projection.

Curve Surfaces. — A curve surface is represented algebraically by an equation containing three variables; for example, x, y, and z. It is geometrical when its equation is algebraic, and expressed in finite terms; and mechanical when the equation is differential, and not algebraic. Curve surfaces are also classed according to the dimensions of the variables in their equations. When the variables are only of the second degree, the surfaces are of the second order; when the variable co-ordinates rise to the third degree, they are surfaces of the third order, and so on.

The most complete treatise on the theory of curve lines is that of Cramer, *Introduction à l'Analyse des Lignes Courbes;* but more or less on the subject is contained in every work treating of the application of algebra to geometry. For curve surfaces, and curves of double curvature, the student may consult Lacroix's large work, *Traité du Calcul Differentiel et du Calcul Integral;* or the *Application de l'Analyse à la Géométrie* of Monge.

CUSCUTA'CEÆ. (Cuscuta, one of the genera.) A very small natural order of Exogens, consisting of but one genus, inhabiting all the quarters of the globe, and related to *Convolvulaceæ;* but distinguished by the imbricate corolla, which does not fall off after flowering, the spiral embryo, and the parasitical habit. Common dodder, a curious thread-like twining plant, found on heaths, belongs to the order.

CUSP. (Lat. cuspis, *point.*) In Astronomy, expresses the points or horns of the moon. In geometry the word is used to denote the point or corner formed by two parts of a curve meeting and terminating there.

Cusp. In Architecture, a term applied by Sir James Hall, in his *Origin of Gothic Architecture*, to the spear-shaped ornaments appended to the several points of trefoil, quatrefoil, &c. arches; but this term, it is to be observed, has not been generally adopted by architects.

CUSPA'RIA BARK. *See* Angustura.

CU'SPIDATE. (Lat. cuspis.) In Botany, a term used in describing the apex of a body, when it gradually tapers into a rigid point. It is also used sometimes to express abruptly acuminate, as the leaf of many *Rubi.*

CU'STARD APPLE. A term applied in the West Indies to the fruit of the *Anona reticulata.*

CU'STOM (Fr. coutume), in Law, signifies generally a right or law not written, but established by long usage. To render a custom valid it has been said that the following qualities are requisite: — 1. Antiquity; *i.e.* that it shall have been used as far back as time of legal memory, that is, the first year of Richard I. 2. Continuance without interruption; 3. Without dispute. 4. It must be reasonable; and 5. Certain. 6. Compulsory. 7. Customs must be consistent with each other. Customs in derogation of the common law must be construed strictly. General customs, relating to all England, are determinable by the judges; but local customs by a jury. An exception to this rule is to be found in the *Custom of the City of London*, which, if questioned, is established by certificate of the mayor and aldermen; with the exception of those customs from which the corporation itself claims a benefit. *Customs* (*coutumes*), in the law of France, were the laws relating both to moveable and immoveable property peculiar to different districts of the kingdom before the Revolution. Districts governed by customs were commonly termed *pays coutumiers*, in contradistinction to the remainder of the realm, which being under the civil law was termed *pays de droit Romain.* The pays coutumiers embraced all the north of France. The valid coutumes were estimated at 140 *general*, or comprehending districts, and 360 *local*, belonging to towns and places; but the enumeration was not exact. The *coutume de Paris* was the most important of all; and it was a generally recognized principle that when a case was unprovided for by local custom, that of Paris was to be applied in aid. Works containing the customary law of a particular district are styled *Coutumiers.*

CU'STOMARY FREEHOLD, in Law, is a superior kind of copyhold; the tenant holding, as it is expressed, by copy of court roll, but not at the will of the lord. *See* Copyhold.

CU'STOMS. (Lat. portoria.) In Finance, duties charged on the importation or exportation of certain commodities; that is, on their being brought into, or sent from, a country. Such duties were levied in antiquity, and form an important part of the revenue of this and most other modern states. Down to the æra of the Revolution, customs duties were charged indiscriminately on most commodities, whether exported or imported; but since the epoch in question they have been almost exclusively laid on imported articles; those laid on exports being, in most instances, imposed rather to check or prevent the exportation of the articles, than in the view of raising revenue.

Were this the proper place for such investigations, it might be easily shown that moderate customs duties are about the least exceptionable of all taxes. They are collected with the greatest possible facility, involving no inquiry into the circumstances of individuals, as is the case with taxes on income or property; nor any interference of any sort with the processes carried on in the arts, as is the case with certain excise duties. By allowing imported goods to be lodged in bonded warehouses, under the joint locks of the king and the importer, the revenue is protected, without its being necessary for the importer to pay the duties till the goods be withdrawn for consumption; so that but little additional capital is required to be at the command of the importing merchant because of the articles in which he deals being subject to duties, and but little addition is consequently made to the price of the goods on account of the profits accruing to the dealers on the duties.

Customs duties should not be carried to such a height as to give any overpowering stimulus to smuggling. They then contradict and defeat the very purpose for which they are intended. Our finance ministers have not, however, been sufficiently alive to this obvious consideration. There can be no articles better fitted to bear customs duties than tobacco and spirits; but the duties with which they are loaded are so extravagantly high, that they occasion a great deal of smuggling, with its accompanying crime and demoralization, and would certainly be a good deal more productive, were they effectually reduced. The existing duties on brandy and geneva are, perhaps, the very worst in our tariff; but they would be about the very best, were they reduced from 22*s*. 6*d*. to 8*s*. or 10*s*. a gallon.

We subjoin an account of the gross and nett amount of the customs duty collected in each of the great divisions of the United Kingdom in 1837 and 1838.

	Gross Receipt, 1837.		Gross Receipt, 1838.		Nett Receipt, 1837.		Nett Receipt, 1838.

CU'TICLE. (Lat. cutis, *skin.*) In Anatomy, the scarf skin. The exterior membranous covering of the body. In its chemical characters it resembles nail, quill, &c., and has the properties of a condensed form of albumen.

Cu'ticle. In Botany, the thin vesicular membrane that covers the external surface of vegetables, and adheres firmly to the cellular substance beneath it. It acts in plants as a means of preventing a too rapid perspiration, and is furnished with respiratory openings called stomata.

CU'TLERY. A term used to designate all kinds of sharp and cutting instruments made of iron or steel, as knives, forks, scissors, razors, &c. The principal seat of the manufacture of British cutlery is Sheffield; and the articles made there are held in the highestest imation in all parts of the world. *See* Hardware.

CU'TTER. A vessel with one mast and a bowsprit, of considerable breadth in proportion to her length. The distinction between a cutter and other vessels of one mast, which are called sloops, is, that in the cutter the jib, has no *stay* to support it.

CU'TTING. An excavation made through land, to conduct a road through it on a level lower than that of the surrounding land. *See* Railroad.

CYA'NIC A'CID. A compound of 26 cyanogen + 8 oxygen = 34 cyanic acid.

CY'ANITE. (Gr. κυανος, *blue.*) A massive and crystallized mineral. It has a pearly lustre, is translucent, and of various shades of blue: it is a silicate of alumina, with a trace of oxide of iron. Only found in primitive rocks.

CYA'NOGEN. (Gr. κυανος, and γιγνομαι, *I am produced;* because it is an essential ingredient of Prussian blue.) Cyanogen is a gas of a strong and peculiar odour, resembling that of rubbed peach leaves; it is obtained by heating *cyanuret of mercury.* Under a pressure of between 3 and 4 atmospheres it becomes a limpid liquid. It extinguishes a taper, is highly poisonous and unrespirable, and burns in contact of air with a rich purple flame. Water absorbs between 4 and 5 times its volume of the gas. It is composed of carbon and nitrogen in the proportions of 12 carbon + 14 nitrogen = 26 cyanogen; it is therefore a bicarburet of nitrogen. Mixed with oxygen it explodes by the electric spark, and is resolved into carbonic acid and nitrogen gas. It combines with hydrogen to produce the *hydrocyanic* or prussic acid: it forms with the metals *cyanurets* or *cyanides.*

CYANO'METER. (Gr. κυανος, and μετρον, *measure.*) An instrument contrived by Saussure for determining the deepness of the tint of the atmosphere. A circular band of thick paper or pasteboard is divided into 51 parts, each of which is painted with a different shade of blue, decreasing gradually from the deepest blue

formed by a mixture of black, to the lightest formed by a mixture of white. The coloured zone is held in the hand of the observer, who notices the particular tint which corresponds to the colour of the sky. The number of this tint, reckoned from the lightest shade, marks the intensity at the time of observation.

CYANO'SIS. (Gr.) In Medicine, the blue disease. A blueness of the body occasionally arises from malformation of the heart. The whole of the body, and especially its exposed parts, becomes a blue or lead colour, in consequence of the administration of nitrate of silver.

CY'ANU'RETS. Compounds of cyanogen. When Prussian blue is boiled in water with red oxide of mercury, and the solution filtered, it yields white or pale buff crystals of *cyanuret of mercury*.

CYANU'RIC ACID. A crystallizable acid, obtained by decomposing urea by heat.

CYBE'LE (Gr. Κυβήλη), in Mythology, was originally the Phrygian goddess of the earth. When her worship was introduced among the Greeks, they confounded her with Rhea, as did the Latins with their Ops. Her rites, like those of the Asiatic deities, in general were celebrated with great excitement; her priests, who were called Galli, Corybantes, Curetes, &c., running about with howlings and clashing of cymbals.

CY'CADA'CEÆ. (Cycas, one of the genera.) In Botany, a very small natural order of arborescent Gymnosperms, inhabiting the tropics of Asia and America. They were formerly referred by Linnæus to the Palms; but in 1825 Brown showed the analogy between *Cycadaceæ* and *Coniferæ*, and hence their present station. Adolphe Brongniart also proved the affinity by finding the vessels contained in the wood of both orders to be, as he says, of the same structure. The only remarkable quality in the order is the production of a kind of sago by the soft centre of *Cycas circinalis*.

CY'CLANTHA'CEÆ. (Cyclanthus, one of the genera.) In Botany, a natural order of Endogens, inhabiting the tropics of the western hemisphere, and allied to *Pandanaceæ*, from which their plaited leaves and spiral flowers divide them.

CY'CLAS, SINGLETON, &c. An article of dress worn both with and without defensive armour, which came into fashion about the reigns of Edward II. and III. in England. It was a mantle or surcoat without sleeves, of silk, cloth, &c., reaching to the knees before and to the calves of the legs behind. It was succeeded by the japon or gyppon, a shorter kind of surcoat.

CY'CLAS. (Gr. *κυκλος, a circle.*) A genus of freshwater air-breathing Gastropods or snails, so named on account of the more or less rounded circumference of the shell in all the species. Of these the following are natives of Britain: — the river cycle (*Cyclas rivicola*, Leach), the largest species of which is not uncommon in the smaller streams communicating with the Thames; the horny cycle (*C. cornea*, Lam.), common in ditches near Battersea; cupped cycle (*Cyclas calyculata*, Drap.); lake cycle (*Cyclas lacustris*, Drap.).

CY'CLE. (Gr. *κυκλος.*) The revolution of a certain period of time which finishes and recommences perpetually. Cycles were invented for the purposes of chronology, and for marking the intervals in which two or more periods, of unequal length, are each completed a certain number of times, so that both begin again exactly in the same circumstances as at first. The cycles used in chronology are three; the *cycle of the sun*, the *cycle of the moon* or *Metonic cycle*, and the *cycle of indiction*.

The *cycle of the sun*, or solar cycle, is a period of time after which the same days of the week recur on the same days of the year. If the number of days in the year were always the same, this cycle could only contain seven years; but the order is interrupted by the intercalations. In the Julian calendar the intercalary day returns every fourth year, and the cycle consequently contains $4 \times 7 = 28$ years; after which period the Dominical letters return in the same order, or the first day of the year and of every month falls again on the same day of the week. The origin of this cycle is unknown; it is supposed to have been invented about the time of the Council of Nice (325); but the first year of the first cycle is placed by chronologists nine years before the commencement of the Christian era. Hence the year of the cycle corresponding to any given year in the Julian calendar is found by the following rule: — *Add nine to the date, and divide the sum by twenty-eight; the quotient is the number of cycles elapsed, and the remainder is the year of the cycle.* Should there be no remainder, the proposed year is the 28th, or last of the cycle. In the reformed calendar this rule can only apply from century to century; for the order is interrupted by the omission of the intercalary day every hundredth year, and is not restored till the end of four hundred years. *See* DOMINICAL LETTER.

The *cycle of the moon* is a period of 19 solar years, after which the new and full moons fall on the same days of the year as they did 19 years before. This cycle was invented by Meton, a celebrated astronomer of Athens, and the chronological period which he founded on it is celebrated in history under the name of the *Metonic cycle*. The Metonic cycle contained exactly 6940 days, which exceeds the true length of 19 solar years by nine and a half hours nearly. On the other hand, it exceeds the length of 235 lunations, or synodic revolutions of the moon, by seven hours and a half only. The framers of the ecclesiastical calendar, in adopting this period, altered the distribution of the lunar months, in order to accommodate them to the Julian intercalation; and the effect of the alteration was that every three periods of 6940 days was followed by one of 6939. The mean length of the cycle was therefore $6939\frac{3}{4}$ days, which agrees exactly with 19 Julian years. A table, therefore, showing the days of the new and full moons for 19 years, would serve to show the days of these phenomena for any year whatever when its number in the cycle is known. The number of the year in the cycle is called the *golden number;* either because it was so termed by the Greeks, who, on account of its utility, ordered it to be inscribed in letters of gold in their temples, or more probably because it was usual to distinguish it by red letters in the calendar. The cycle is supposed to commence with the year in which the new moon falls on the 1st of January. This happened in the year preceding the commencement of our era; hence to find the number of any year in the lunar cycle, or the golden number of that year, we have this rule: — *Add one to the date, and divide by nineteen; the quotient is the number of cycles elapsed, and the remainder is the year of the cycle.* Should there be no remainder, the proposed year is the last or 19th of the cycle.

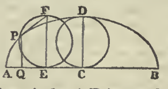
Cycle of indiction, or *Roman indiction*, a period of 15 years; not astronomical, like the two former, but entirely arbitrary. Its origin and the purpose for which it was established are alike uncertain; but it is conjectured that it was introduced by Constantine the Great, about the year 312 of the common era, and had reference to certain judicial acts that took place under the Greek emperors at stated intervals of 15 years. In chronological reckoning, it is considered as having commenced on the 1st of January of the year 313. By extending it backwards to the beginning of the era, it will be found that the 1st year of the era corresponded with the 4th of the cycle. In order, therefore, to find the number of any year in the cycle of indiction, we have this rule: — *Add three to the date; divide the sum by fifteen, and the remainder is the year of indiction.* *See* CALENDAR.

CY'CLIC CHORUS. The chorus which performed the songs and dances of the Dithyrambic Odes at Athens. They derived their name from the circumstance of their dancing round the altar of Bacchus in a circle (*κυκλος*), and were thus distinguished from the square (*τετράγωνος*) choruses of tragedy.

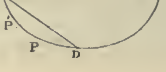
CY'CLIC POETS. (Gr. *κυκλος.*) This term was applied to a succession of Epic poets who followed Homer, and wrote merely on the Trojan war and the adventures of the heroes immediately connected with it, keeping, as it were, to one circle (*κυκλος*) of subjects. None of their works have come down to us.

CY'CLOBRA'NCHIANS, *Cyclobranchiata.* (Gr. *κυκλος*, and *βραγχια, gills.*) The name of an order of hermaphrodite Gastropodous Mollusks, including those in which the branchiæ consist of little tufts or pyramids attached in a circular arrangement to the inner surface of the margin of the mantle.

CYCLOI'D, or TROCHOID. (Gr. *κυκλος*, or *τροχος, wheel;* and *ειδος, form.*) In Geometry, one of the transcendental curves, described by a point P in the circumference of a circle which rolls along an extended straight line A B until it has completed a revolution. Some of the properties of the curve are obvious from this definition. The line A B, which is called the base of the cycloid, is equal to the circumference of the generating circle; and CD, which is the axis of the cycloid, is equal to the diameter. In any position E P F of the generating circle, A E is equal to the arc E P, A Q the absciss = A E − Q E = arc E P − sine EP, and PQ the ordinate = 1 − cosine of E P.



It is also easy to prove that the whole length of the cycloid A D B is equal to four times C D, and the whole area or space between the curve and its base triple that of the generating circle. A portion of the curve D P, counted from its summit, is double of F P, the supplemental chord of the arc E P; and F P is also a tangent to the cycloid at P. The curve has many other remarkable properties which have been discovered by more recondite investigations. Its *involute*, or the curve formed by unfolding a thread or flexible line from its convex side, is a cycloid equal and similar to the original. If a heavy body descends by the force of gravity in an inverted cycloid, the velocity which it acquires is exactly proportional to the length of the cycloidal arc P D; so that from whatever point (P, P′) it may begin to fall, it will arrive at the lowest point D



in precisely the same time. If a body is to descend by the force of gravity from a point A to another point D not in the same vertical, it will accomplish the passage in a less time by describing the cycloid A P D than by moving in the straight line A D, or in any other path whatever. *See* BRACHYSTOCHRONE.

The cycloid may be made to assume an endless variety of forms by placing the tracing point not in the circumference of the generating circle, but without or within it, though still in the same plane. When the tracing point is without the circle, the curve has its base shortened, and is called the *curtate* or *contracted cycloid*. If the point is within the circumference, the curve is called the *prolate* or *inflected cycloid*.

Few curves have afforded finer scope for the exercise of modern geometry than the cycloid. Its properties successively engaged the attention of Roberval, Fermat, Descartes, Pascal, Slusius, Wren, and Wallis. Huygens rectified the curve so early as 1657; and having afterwards discovered its isochronism, or the remarkable property that all bodies gliding along it will descend from any point in the same time, and likewise that it produces a similar cycloid by its development, he applied these discoveries to the improvement of the pendulum, and showed how a perfectly synchronous vibration could be procured, theoretically at least, by causing a flexible rod to vibrate between cycloidal cheeks. Its property of being the line of swiftest descent was discovered by John Bernoulli in 1697.

CYCLOI'DES. (Gr. κυκλος.) A name given by Agassiz to one of his orders of fishes, the species composing which have scales composed of simple layers with smooth margins, but often ornamented on their exterior surface with different figures impressed upon all the layers: these are of horn or bone without enamel; the scales of the lateral line, instead of being flat, are funnel-shaped; the contracted part applied against the disk of the scale forms the tube by which the mucus exudes which covers the fish. The families included in the *Cycloid* order are, *Labroides*, *Muges*, *Atherines*, *Scomberoids*, *Gadoids*, *Gobioids*, *Murenoids*, *Lucioids*, *Salmonoids*, *Clupeoids*, and *Cyprinoids*.

CY'CLOPÆ'DIA. (More correctly *Encyclopædia*, from the Greek words ἐν κύκλῳ παίδεια; *instruction in a circle*.) A work containing definitions or accounts of the principal subjects in one or all departments of learning, art, or science. Its arrangement may be either according to divisions into the various sciences, &c., or the subjects may be arranged and treated in alphabetical order. The *Encyclopédie Françoise*, or *Dictionnaire Encyclopédique*, and the *Encyclopædia Britannica*, have been the most celebrated works of this species; but the earliest appears to be the *Lexicon Technicum* of Harris, published in 1706. The great French work, the *Encyclopédie Methodique*, consists, not of one, but of a series of encyclopedias or dictionaries. *See* DICTIONARY, ENCYCLOPÆDIA.

CYCLO'PEAN. An epithet applied to certain huge structures the remains of which are found in many parts of Greece, Italy, and Asia Minor, the architecture of which was totally different in style from that which prevailed during the historical ages. The epithet originated in the Grecian tradition that assigned these edifices to the gigantic strength of the Cyclops. It is most probable that they were really raised by the Pelasgians, the predecessors or ancestors of the later Greeks; and a gradual progress may be traced in them from the extreme of rudeness to a degree of symmetry that indicates an approach to the elegance of Grecian architecture.

CYCLO'PES. (Gr. κυκλος, *circle* and ωψ, *eye*.) In Mythology, a race of gigantic beings fabled by the Greeks to dwell in Sicily, where they assisted Vulcan in forging the thunderbolts of Jupiter. They had only one eye, round, and situated in the centre of the forehead. The most celebrated among them was Polyphemus, whose exploits have formed a prolific theme for the poets of antiquity. His attachment to the nymph Galatea, is happily described in an idyl of Theocritus; and the 9th book of the *Odyssey* contains a graphic account of his savage propensities, and of the loss of his eye by the stratagem of Ulysses.

CYCLO'SIS. (Gr. κυκλος.) A term applied by Schultz to that general motion of latex or the vital fluids of plants, which passes through vessels of a peculiar kind, and which are diffused through the system of plants without interruption; in distinction to *rotation*, or the movement of fluids in separate cells, as in Chara, Valisneria, &c. According to this physiologist, the phenomenon of cyclosis is confined to the highest forms of vegetation, while that of rotation is characteristic of the more imperfect orders of plants.

CY'CLOSTO'MA. (Gr. κυκλος, and στομα, *a mouth*.) A genus of air-breathing Gastropods or snails; so called on account of the circular form of the aperture of the shell. *Cyclostoma elegans* and *Cycl. productum* are both natives of England.

CY'CLOSTO'MES, *Cyclostoma* (Gr. κυκλος, and στομα *a mouth; round-mouthed*.) A tribe of cartilaginous fishes, including those in which the mouth is surrounded by a circular lip, forming a large sucker, as in the lamprey.

CY'GNUS. (Lat. *the swan*.) In Astronomy, one of the old constellations in the northern hemisphere.

CY'GNUS. In Ornithology. *See* SWAN.

CY'LINDER. (Gr. κυλινδω, *I roll*.) In Geometry, a solid which may be conceived to be formed by the revolution of a rectangular parallelogram about one of its sides. The surface of a cylinder, not including the two ends, is equal to the rectangle formed by multiplying the circumference of its base into its altitude; and the solid content is equal to its altitude multiplied into the area of its base. The cone, the sphere, and the cylinder have a remarkable relation to each other, first discovered by Archimedes: namely, that the cone is one third of the cylinder, having the same base and altitude; and the inscribed sphere two thirds of the cylinder; or the cone, the sphere, and the cylinder are to each other as the numbers 1, 2, and 3.

CYLI'NDROID. (Gr. κυλινδρον, *cylinder*, and ειδος, *form*.) A solid which differs from a cylinder in having ellipses instead of circles for its ends or bases.

CY'MA, or CYMATIUM. (Gr. κυμα, *a wave*.) In

Architecture, a moulding, taking its name from its contour resembling that of a wave, being hollow in its upper part, and swelling below. Of this moulding there are two sorts: the cyma recta,

just described; and the cyma reversa, whose upper part swells, whilst the lower is hollow. By the workmen these are called ogees.

CYMA. (Gr. κυημα, *a fœtus*.) In Botany, a form of inflorescence consisting of a solitary flower seated in the axilla of dichotomous ramifications, as in *Sambucus*. This term is also sometimes improperly used, in place of coma, to express the head of a forest tree.

CY'MBALS. (Gr. κυμβαλον, from κυμβος, *hollow*.) Brass musical instruments of percussion, played in pairs by striking one against the other. They are circular, about six or eight inches diameter, attached to leather mountings, by which they are held. Cymbals are musical instruments of great antiquity, though there is considerable doubt as to who was the inventor. They were employed by the Greeks in the festivals of Cybele and Bacchus, and indeed by nearly all the nations of antiquity. The cymbals and the *crotola* (which see) were used together.

CY'MBIUM. In Natural History, a name given by many writers to a kind of sea-shell, commonly called the gondola. It belongs to the genus *concha globosa*, or *dolium*.

CYNA'PIA. A crystallizable alkaline base obtained from the *Æthusa cynapium*.

CY'NARA'CEÆ. (Cynara, one of the genera.) In Botany, one of the divisions of the great group of *Compositæ*, admitted by Jussieu. It contains the thistle, the artichoke, and similar plants, having their capitula surrounded by a hard spiny or lacerated involucrum, and long equal tubular florets with an inflated limb. They are also called *Cynarocephalæ*.

CYNAROCEPHALÆ. *See* CYNARACEÆ.

CYNARRHO'DIUM. (Gr. κυων, *a dog*, and ῥοδον, *a rose*.) In Botany, a fruit with distinct ovaria, and hard indehiscent pericarpia enclosed within the fleshy tube of the calyx, as in *Rosa*.

CY'NICS. A sect of philosophers among the Greeks, so called from their snarling humour, and their disregard of the conventional usages of society; the name being derived from κυων, *a dog*. It is difficult to give any satisfactory account of the tenets of this sect, as during all the period of its existence it was in a state of constant fluctuation, and, like most of the philosophical systems of antiquity, derived its character and complexion from the peculiar temperament and disposition of those who embraced it. But amid all the follies and incongruities by which it was disfigured, and which exhibited themselves chiefly in a contemptuous neglect of all science and art, and of all the comforts and charities of life, it is impossible not to admit that its grand aim was to inculcate the love of rigid virtue and a contempt of pleasure. On this point the testimony of Horace,—himself a zealous adherent of the school of Aristippus, the very opposite of the cynical sect,—even were there no other, must be held to be conclusive; and, according to his opinion, the aim of the cynical philosophy was to induce every man to become

Virtutis verae custos, rigidusque satelles.

This sect was founded by Antisthenes, a disciple of Socrates, who sought to imitate his master in carelessness of outward splendour and contempt of riches; but his indifference to these things soon degenerated unhappily into a love of ostentation, shown by a display of poverty. Thus he and many of his followers rejected not only the conveniences but the common decencies of life, and lived in rags and filthiness; while they sneered bitterly at the rest of the world, instead of endeavouring to teach it to cultivate the pure reason of which they professed themselves to be the only followers. Of this sect was the

famous Diogenes, whose meeting with Alexander the Great is too well known to require being noticed in this place.

CY'NIPS. (Gr. κυω, *I am pregnant.*) A Linnæan genus of Hymenopterous insects, belonging to that section which has not a poisonous sting. The ova of this genus are deposited in living trees, and the irritation excited by their presence gives rise to the formation of the excrescences called galls.

CY'NOMORIA'CEÆ. (Cynomorium, one of the genera.) In Botany, a natural order of Rhizanths, at present but little known. One species is a native of Malta, and was formerly supposed to possess great medicinal powers as an astringent: it figures in old officinal catalogues under the name of *Fungus melitensis*.

CY'NOSA'RGES. A sort of academy in the suburbs of Athens, situated near the Lyceum; so called from the mythological story of a white dog (κῦνος αργου), which, when Diomus was sacrificing to Hercules, the guardian of the place, carried off part of the victim. Besides possessing several temples erected in honour of Hercules, Alcmene, and other mythological personages, it was chiefly famed for its gymnasium, in which foreigners or citizens of half blood used to perform their exercises; and as being the place where Antisthenes instituted the sect of the cynics, and taught his opinions.

CY'NOSURE. (Gr. κυων, *a dog*, and ουρα, *a tail.*) Literally the tail of a dog, applied by some philosophers to the constellation Ursa Minor, by which the ancient Phœnicians used to be guided on their voyages: whence it has been borrowed by the language of poetry, in which it signifies "a point of attraction:"

> Where perhaps some beauty lies,
> The cynosure of neighbouring eyes. *L'Allegro*, 79.

CY'NTHIUS and CY'NTHIA. In Mythology, surnames given by the ancient poets to Apollo and Diana; from Cynthus, a mountain of the island of Delos, on which they are fabled to have been born. (*Virg.*, Eclog. 6.3. *Hor.*, Od. III. 28.)

CYPERA'CEÆ. (Cyperus, one of the genera.) A natural order of Endogens, inhabiting the marshes, ditches, streams, &c. of all countries. They closely resemble *Graminaceæ;* but are distinguished from them by the stems being solid and angular, not round and fistular, and by there being no diaphragms at the articulations. They approach *Juncaceæ* and *Restiaceæ*, but are known at once by the sheaths of their leaves not being split. The entire order has lately been re-arranged by Nees Von Esenbeck and Kunth. Their sensible properties are unimportant. *Carex arenaria* affords one of the European substitutes for sarsaparilla.

CYPHE'LLÆ. (Gr. κυφος, *a tubercle.*) A term used in describing lichens, to denote pale tubercle-like spots on the under surface of the thallus.

CY'PHER, or CIPHER. In Diplomatic affairs, "an occult manner of writing, legible to those only who possess the key or secret." This art, in a variety of forms, has been more or less practised in every civilized country; and has been cultivated by the moderns in particular to such a degree as to have acquired the importance of a distinct science, under the names *Cryptography*, *Polygraphy*, *Stenography*, &c. To give a general exposition of the principles of the art, it would be necessary to enter into minute details inadmissible in a work of this kind; but the reader will find in *Rees's Cyclopædia* a full and learned disquisition on the subject.

CY'PHONISM. (Gr. κυφων, *an instrument of punishment.*) A species of punishment frequently resorted to by the ancients, which consisted in besmearing the criminal with honey, and then exposing him to insects. This punishment was carried into effect in various ways, but chiefly by fastening the sufferer to a stake, or extending him on the ground with his arms pinioned.

CYPRÆ'A, *Cowry*. The name of a Linnæan genus of the *Vermes Testacea*, characterized by a subovate smooth shell, with a linear aperture extending from one end of the shell to the other, and transversely furrowed or dentated in the mature state. The genus is retained without subdivision, and forms part of the *Buccinoid* family of the Pectinibranchiate order of Gastropods of the system of Cuvier.

This genus is remarkable for the difference of form which exists in the young and old states of the shell: in the former the lip is thin, and the aperture wide, but the mantle is progressively developed until its lobes extend over the columella on the one side and the lip on the opposite side of the aperture, covering them with successive layers of nacreous shell, and at length diminishing the aperture to a narrow linear form. One species of cowry (*Cypræa moneta*, L.) is commonly used by the natives of certain parts of Africa and other semi-barbarous nations as a medium of monetary exchange.

CYPRI'NUS. (Lat. cyprinus, *a carp.*) A Linnæan genus of abdominal fishes, now the type of a family of Malacopterygians in the system of Cuvier, and of Cycloid fishes in the system of Agassiz; including the genus *Cyprinus* proper, or carps; *Barbus*, or barbels; *Gobio*, or gudgeons; *Tenca*, tenches; *Abrama*, breams; *Leucisens*, minnows; *Cirrhinus; Labes; Catastomus;* and *Gonorhynchus.*

CY'PSELA. (Gr. κυψελη, *a bee-hive.*) In Botany, one-seeded, one-celled, indehiscent fruit, with the integuments of the seed not cohering with the endocarp: in the ovarium state evincing its compound nature by the presence of two or more stigmata; but nevertheless unilocular, and having but one ovule. Usually called an *Achenium.*

CYRE'NIANS. The philosophers of a school founded at Cyrene, a Grecian colony on the northern coast of Africa, by Aristippus, a disciple of Socrates. They held, with the Epicureans, that pleasure was the only good and pain the only evil, and were not at such pains as the latter to prove that the first could only attend on virtuous conduct; they also differed from them in not considering absence from pain of itself to be a pleasure of the highest order. But though these philosophers held that pleasure should form the ultimate object of pursuit, and that it was only in subserviency to this that fame, friendship, and even virtue are to be desired, still there were many points in their philosophy calculated to command general sympathy. It is impossible not to admit that, with all the defects of the system, its object, as Dryden says in reference to Horace, is to render us happy in relation to ourselves, agreeable and faithful to our friends, and discreet, serviceable, and well-bred in relation to those with whom we are obliged to live and converse. Perhaps the best view of the philosophy of this sect is to be obtained from the Satires and Epistles of Horace, in which the versatility of disposition, politeness of manners, and knowledge of the world that distinguished the Cyrenians, are set forth with great clearness, and with all the ardour of an enthusiastic disciple. The grand principles of Aristippus are thus happily described in the couplet —

> Omnis Aristippum decuit color et status et res,
> Tentantem majora, fere præsentibus æquum:

and the poet's own partiality for this system of philosophy, and its accommodating character, are thus exhibited: —

> Nunc in Aristippi furtim præcepta relabor,
> Et mihi res non me rebus subjungere conor.

CY'RTANDRA'CEÆ. (Gr. κυρτος, *crooked*, and ανηρ, *a male;* Cyrtandra, the name of one of the genera.) A natural order of Monopetalous Dicarpous Exogens, inhabiting the tropics, and closely allied to *Gesneraceæ*, *Bignoniaceæ*, and *Pedaliaceæ;* from the former differing only in never producing an inferior ovary, their deeply lobed placentæ, their siliquose fruit, and the want of albumen; from *Bignoniaceæ*, by their habit, their minute apterous seeds, one-celled ovary, with two double parietal placentæ; from *Pedaliaceæ*, in nothing except their minute indefinite seeds, and the membranous not woody texture of the fruit and placentæ.

CY'STIBRA'NCHIANS, *Cystibranchia*. (Gr. κυστις, *the bladder*, and βραγχια, *gills.*) A family of Isopodous *Crustaceæ*, comprehending those which have the branchiæ lodged in vesicular cavities.

CY'STIC OXIDE. (Gr. κυστις.) A species of urinary calculus, composed of a peculiar animal matter.

CY'STICS, *Cystica*. (Gr. κυστις.) Rudolphi thus denominates the order of Entozoa in which the body is terminated by a cyst peculiar to one individual or common to many. The hydatid in the brain of sheep, and the parasite which produces measly pork, are examples of this order.

CYSTI'TIS. (Gr. κυστις.) Inflammation of the bladder.

CY'STOCE'LE. (Gr. κυστις, and κηλη, *a tumour.*) A hernia or rupture formed by a protrusion of the bladder.

CYSTO'TOMY. (Gr. κυστις, and τεμνω, *I cut.*) The operation of cutting into the bladder for the extraction of a stone or other extraneous substance.

CYTHERÆ'A. In Mythology, a name given to Venus, from the island Cythera, where she was worshipped with peculiar veneration. (*Ovid. Fast.* iv. 285.)

CY'TINA'CEÆ. (Cytinus, one of the genera.) In Botany, a natural order of Rhizanths inhabiting the south of Europe, the Cape, and Guinea. They are very little known, and have no sensible properties of importance. Pelletier says that Cytinus has the property of precipitating gelatin without containing tannin.

CYZICE'NUS. In Ancient Architecture, a large hall decorated with sculpture; and so called from the inhabitants of Cyzicus, who were celebrated for their magnificence in building.

CZAR, ZAR, or TZAR. A title given to their monarch by several Sclavonic tribes. In Russia, Ivan II. adopted in 1579 the title of Czar of Moscow. The eldest son of the czar was termed Czarovicz; but after the death of Alexis, the murdered son of Peter I., this title was no more used, until revived by Paul I., in 1799, in favour of his second son, the late grand duke Constantine. The consort of the emperor of Russia is styled *Czarina.*

D.

D. The fourth letter in the Hebrew alphabet, and those derived from it, is the medial of the order of dentals or palato-dentals; and is susceptible of various interchanges, particularly in the German and English languages. As an abbreviature, D has several significations; thus, D. stands for Doctor, — M. D. Doctor of Medicine, — D. D. Doctor of Divinity, &c. Among Roman writers, D. is used for Divus, Decimus, Devotus, Diebus, &c. D. M. in the Roman epitaphs signifies Diis Manibus; but, on other occasions, Deo Magno, or Diis Magnis. As a Roman numeral, D signifies five hundred: in this case, it is more correct to write IↃ.

D. In Music, the note on the third line in the bass or F clef, on the fourth space in the tenor clef, on the third space in the counter-tenor clef, and on the fourth line in the treble or G clef.

DA CA'PO. (It.) In Music, usually written short, D. C. An instruction to the performer in such airs as end with the first strain, that the song must be begun again and ended with the first part.

DA'CELO. One of those generic terms which Dr. Leach framed by transposing the letters of the name of the typical or Linnæan genus from which the species so designated were dismembered; in the present case, the word is obtained from *Alcedo*, and is applied to a large Australian species of Passerine bird, nearly allied to the kingfisher.

DACRYO'MA. (Gr. δακρυω, *I weep.*) A disease of the lachrymal duct of the eye, by which the tears are prevented passing into the nose, and therefore trickle over the face.

DACTI'LIOGLYPH. (Gr. δακτυλιος, *a ring;* and γλυφω, *to engrave.*) In ancient gem sculpture, the inscription of the name of the artist on a gem.

DACTILIO'GRAPHY. (Gr. δακτυλιος, and γραφω, *to write.*) In gem sculpture, the science of gem engraving.

DA'CTYL. (Gr. δακτυλος, *the finger.*) The name of a metrical foot in Greek and Latin poetry, consisting of a long and two short syllables; as in the word *cārmĭnă*. In the English and German languages, where accent determines quantity, the word dactyl means an accented followed by two unaccented syllables; as in *quantity, liebliche.*

DA'CTYLI. Priests of Cybele in Phrygia; so called, according to Sophocles, because they were five in number, thus corresponding with the number of the fingers (δακτυλοι), from which the name is derived. Their functions appear to have been similar to those of the Corybantes and Curetes, other priests of the same goddess in Phrygia and Crete.

DA'CTYLO'LOGY. (Gr. δακτυλος, *a finger*, and λογος, *discourse.*) The art of spelling words by placing the fingers in such positions as to signify the letters of the alphabet.

DACTYLO'PTEROUS. (Gr. δακτυλος, and πτερον, *a wing or fin; finger-finned.*) A fish is said to be so when the inferior rays of its pectoral fin are partially or entirely free. The term *Dactylopterus* has been applied by Lacepede to a genus of Gurnards, remarkable for the great expansion of their pectoral fins. The most common and best known species of this genus inhabits the Mediterranean, and is the *Trigla volitans* of Linnæus, or the flying gurnard. It is sometimes confounded with the true flying fish (*Exocœtus*).

DA'DO. (It. *a die.*) In Architecture, the die, or that part in the middle of the pedestal between the base and cornice. It takes its name from being a cube like a die.

DÆ'DALUS. In Fabulous History, the great grandson of Erechtheus king of Athens, is celebrated as the most ancient statuary, architect, and mechanist of Greece. To him is ascribed the invention of the saw, the axe, the plummet, and many other tools and instruments; and to such a degree did he excel in sculpture, that his statues are fabled to have been endowed with life. For the alleged murder of his nephew he was obliged to quit Athens, whence he repaired to Crete, then under the sway of Minos, by whom he was favourably received. Here he constructed the famous labyrinth, on the model of the still more famous one of Egypt; but having assisted the wife of Minos in an intrigue with Taurus (*see* MINOTAUR), he was, by a strange fatality, confined to this very labyrinth along with his son Icarus. By means, however, of wings, which he formed of linen or feathers and wax, Dædalus and his son contrived to make their escape. The former pursued his aërial journey, and arrived safely in Sicily; but the latter having soared too near the sun, in consequence of which the wax that fastened the wing was melted, dropped into and was drowned in the sea (thence called the *Icarian*). In Sicily Dædalus continued to prosecute his ingenious labours, and lived long enough to enrich that island with various works of art. From the plastic powers of Dædalus, the ancient poets used to regard his name as synonymous with *ingenious*, as in the phrase *Dædaleum opus;* and in a somewhat similar sense Lucretius applies it to the earth, in order to describe its vernal vegetation, —

> —— tibi suaves Dædala tellus
> Submittit flores.

A few years ago the name of Dædalus, which had been appropriated by various artists in the history of Grecian art, was assumed by the constructors of some ingenious automata, in memory of the grand impressions which the works of Dædalus had produced.

DA'GON. (Heb. דג, dag, *a fish.*) One of the principal divinities of the ancient Phœnicians and Syrians, and more especially of the Philistines. The origin, attributes, and even the sex of this divinity, are all wrapt in the most profound obscurity; but the sacred writers concur in assigning to him such a degree of authority as must place him on a level with the Jupiter of the Greeks and Romans. The reverence in which he was held by the Philistines, and the remarkable circumstances attending his downfall, will be found fully detailed in Judges, c. 16., and 1 Samuel, c. v.; but we cannot refrain from transferring to our pages Milton's graphic sketch of the leading features of his history: —

> —— Next came one
> Who mourned in earnest when the captive ark
> Maimed his brute image, head and hands lopt off
> In his own temple, on the grunsel edge,
> When he fell flat, and shamed his worshippers:
> Dagon his name, sea monster, upward man
> And downward fish; yet had his temple high
> Reared in Azotus, dreaded through the coast
> Of Palestine, in Gath and Ascalon,
> And Accaron and Gaza's frontier bounds.

The *Samson Agonistes*, as is well known, exhibits the great importance of this divinity; and the

> —— solemn feasts,
> With sacrifices, triumph, pomp, and games,

celebrated to his honour by the Philistines.

DAGUE'RROTYPE. The name given to a process lately introduced by Daguerre, an ingenious French artist, by which the images from the lens of a camera obscura, as is supposed, are fixed on metal plates. It has been our good fortune to see several of the productions of this surprising discovery, and we regret that words cannot convey the impression they made on us. With the exception of local colour, they present nature herself to the spectator. The qualities of objects are so clearly expressed that silk could not in the representation be mistaken for satin, nor marble for plaster. The sky is given with as different an expression of quality from stone as that substance is from the ground on which it stands. The productions we saw were nearly uniform in size, being about 10 inches by perhaps 6 or 7; and notwithstanding the small space within which the views are confined, we could by means of a lens count the strands in a rope. This extraordinary discovery must not be confounded with that of an ingenious gentleman (Mr. Talbot) of this country, in which what in nature is in light becomes a dark space in the representation, and the parts that are dark are exhibited in masses of light. In Daguerre's discovery the objects are lighted as they are in nature, with all the sparkling effects which the sun scatters on them: the intensity of tone in the foregrounds is balanced by the aërial effects in the distances; in short, the only step wanting to rival the original is to impart to these self-created pictures that which the father of colour, the sun, bestows upon all things beneath him, namely, colour. Mr. Talbot's process has been made known by a paper read before the Royal Society, and some have called his specimens Photogenic pictures. *See* PHOTOGENIC.

DAI'RY. (Dey, *milk*, obsol. Eng.) An apartment in a house, or a separate building, for the purpose of holding milk, and manufacturing it into butter, cheese, or other dairy produce. On a small scale, where butter only is made from milk, the dairy may be a room in the north side of the dwelling-house; or it may form one of the offices connected with the kitchen court. The requisites for the room to contain the milk are — an equal temperature throughout the year, viz. between 48° and 55°; sufficient ventilation to carry off all bad smells and impurities in the air; and the exclusion of flies and other insects. An equable temperature is maintained by thick or by hollow walls, and by double windows. In winter the temperature is somewhat raised by the warm milk, and in summer it is cooled to the degree required by ventilation and the evaporation of water poured on the floor. The ventilation is effected by opening the glazed sashes of the windows, and supplying their places by wire shutters; and indeed one of the best modes of arranging the windows of a dairy is to have wooden shutters outside for closing in the most severe weather in winter; next a fixed frame of wirework to exclude the flies; and within this, at three or four inches distance, the glazed sash, which should be made to open. A dairy on a large scale is most conveniently arranged as a detached building; in which case, it contains a milk-room, a churning-room, and a dairy scullery, or place for

scalding the utensils. If cheese is to be made, a room will be required for the cheese press, and another for drying the cheeses.

The quantity of milk raised in the vicinity of London for the supply of the inhabitants, and the revenue derived from the sale of it, show the importance of this article. In his valuable work on cattle, their breeds, &c. "Mr. Youatt estimates the number of dairy-cows, at present kept in London and its environs, at 12,000; affording, on Mr. Middleton's hypothesis, an annual supply of 38,400,000 quarts of milk. Now, as milk is sold by the retailers at from 3*d*. to 4*d*. a quart, after the cream is separated from it, and as the cream is usually sold at from 2*s*. 6*d*. to 3*s*. a quart, and there is reason to suspect that a good deal of water is intermixed with the milk, we should hardly be warranted in estimating that the milk, as obtained from the cow, is sold at less than 5*d*. a quart, which gives 800,000*l*. as the total price of the milk consumed in the city and its immediate vicinity." (*M'Culloch's Statistics*, 2d ed. vol. i. p. 490.)

DA'IS. (Fr.) In Architecture, the platform or raised floor at the upper end of a dining hall, where the high table stood; also the seat with a canopy over it for those who sat at the high table.

DALMA'TICA. A long white gown with sleeves; worn by deacons in the Roman Catholic church over the *alb* and *stole*. It was imitated from a dress originally worn in Dalmatia, and imported into Rome by the emperor Commodus, where the use of it gradually superseded the old Roman fashion of keeping the arms uncovered. A similar robe was worn by kings in the middle ages at coronations and other solemnities.

DA'MAGE-FEASANT. In Law, a beast is said to be so, when found in another person's ground without his leave or licence; in which case the tenant may distrain or impound it: but at his own peril, if the accident have happened through his own negligence in not repairing the fences of his close. Possession, without title, is sufficient to empower the tenant to distrain damage-feasant. Proper notice is, however, to be given; and if the owner of the estate tender amends, it is unlawful to detain them.

DA'MAGES. (Lat. damna.) In English Law, the recompence awarded by a jury to a plaintiff, in certain forms of action, for the loss or *damage* he has sustained by the injury committed by the defendant. At *common law*, damages are recoverable in personal and mixed actions. In actions upon the case, trespass, &c., a certain amount of damages, sufficient to cover all the hurt really sustained by the plaintiff, is alleged or *laid* in the declaration; and it is the duty of the jury to inquire the real amount of damages, and assess it accordingly. In the action of debt, where the amount due is something certain, the damage laid is now merely nominal, for the injury supposed to be done by the detention of the debt; the jury, therefore, award a nominal sum only. Damages are also allowed in actions upon a variety of statutes, and sometimes double or treble damages; in which case the plaintiff is entitled to twice or three times the amount awarded by the jury.

DA'MASK. (From *Damascus*, where it was anciently made.) A woven fabric produced by a particular construction and management of the loom, in which are represented various figures of flowers, fruit, leaves, &c. The chief seat of this manufacture is Dunfermline in Fifeshire, and Lisburne and Ardoyne near Belfast. The best damasks are of linen; those of cotton are cheaper, but less elegant and durable.

DAMASKEE'NING. The art of inlaying iron and steel with gold and silver, originally practised at Damascus in Syria.

DAMA'SSIN. A species of woven damask with gold and silver flowers.

DAME (probably a corruption of the Lat. domina, *a mistress*), was formerly a title of honour, and is still used in the English law to denote the wife of a knight or baronet. Dame was also the designation of nuns of the Benedictine and certain other ancient orders.

DA'MPER. An iron plate sliding backwards and forwards in a groove, and so arranged as to enlarge or contract, and occasionally close the chimneys of furnaces, steam-boilers, &c. so as to increase or diminish the draught of air through the fire, and consequently regulate the intensity of the combustion.

DAMPS. (Germ. dampf, *vapor*.) The noxious exhalations of mines and excavations. The carburetted hydrogen of coal mines is called *Fire Damp*; carbonic acid is termed *Choke Damp*.

DA'NCING (Germ. tanzen), may be defined to be a graceful movement of the figure, accompanied by gestures and attitudes indicative of certain mental emotions, and by measured steps in harmony with a piece of music arranged for the purpose. The great antiquity of dancing is attested by history, both sacred and profane. It consisted at first, probably, of nothing more than gesticulation and moving in a procession; in which sense it formed part of the celebration of the religious rites of the ancient Hebrews and Egyptians. But the Greeks, who are confessedly indebted to the Egyptians for the elements of their religion and literature, though these were afterwards refined by them to such a degree as nearly to obliterate all traces of their origin, soon polished and improved these sacred rites, and introduced them into all the festal ceremonies of which their elegant mythology was composed. In this they were, as usual, imitated by the Romans. If we believe Scaliger, the early bishops of the church were styled *præsules*, because (as the word literally implies) they led off the dance at their solemn festivals; and this practice continued in the church till the 12th century. Almost every country can boast of national dances peculiar to the inhabitants; which it is rare to see so well performed when adopted by others. Of these the best known to us are the *tarantella* of the Neapolitans, the *bolero* and *fandango* of the Spaniards, the *mazourek* and *krakowiaque* of Poland, the *cosaque* of Russia, the *redowac* of Bohemia, the *quadrille* and *cotillon* of France, the *waltz* and *gallopade* of Germany, and the *reel* of Scotland.

DA'NEGELT. A tribute of twelve pence laid by the Danes upon the Anglo-Saxons upon every hide of land throughout the realm.

DA'NNEBROG. An ancient Danish order of knighthood, supposed to have been founded in 1219; revived in 1693, and re-constituted in 1808.

DANS. Small trucks or sledges used in coal mines.

DA'PHNE. (Gr. Δαφνη.) In Grecian Mythology, a nymph of Diana, the daughter of the river god Peneus. She was beloved by Apollo; but she resisted all his attempts to excite in her a mutual attachment, and at last betook herself to flight. On being hotly pursued by the god, she invoked the earth to swallow her up, when her prayer was granted, and she was immediately changed into a laurel tree, which was ever after sacred to Apollo, and regarded as the symbol of fame and glory. (*Ovidi. Met.* l. x.)

DA'PHNIA. A genus of the Entomostracous or lower-organized Crustaceans, belonging to the order *Branchiopoda*, and the section *Lophyropoda*. The most common species and type of this genus, *Monoculus pulex* of Linnæus, is a favourite and interesting microscopic object. Its body is compressed, oval, and inclosed in a large bilobed carapace; the two lobes being connected together along the back and open below, resembling a bivalve shell. The head is prolonged into a snout, and provided with a single central compound eye. The chief organs of swimming are the modified antennæ, which have a long basal joint, supporting two jointed branches beset with long bristles. It is by the sudden contraction of these organs that the little animalcule propels itself through the water by a series of jerks. The true legs are ten pairs, very small, having a respiratory vesicular organ attached to the second joint; the first eight pairs have the terminal joint dilated and hairy. The eggs are incubated in a kind of marsupial pouch, situated towards the dorsal aspect of the lower end of the body: in five days the young are excluded. The *Daphnia pulex* is extremely prolific; and as it assumes a rose-red colour in summer time, the swarms which abound in stagnant water often impart to it so deep a colour as to give rise to a suspicion and popular belief that it is occasioned by blood.

DA'RIC. A Persian gold coin (so called by the Greeks, from Darius, the name of several Persian sovereigns), having upon the obverse an archer crowned and kneeling upon one knee, and on the reverse a quadrata incusa, or deep cleft. The weight of the daric is about 130 grains.

DAROO' TREE. The *Ficus sycamorus*, or Egyptian sycamore.

DA'RTER. Certain web-footed birds of the Pelican family are so called. *See* PLOTUS.

DASH. (Etym. uncertain.) In Music, a small mark, thus ', denoting that the note over which it is placed is to be performed in a short and distinct manner.

DA'SYPRO'CTA. (Gr. δασυς, *hairy*, and πρωκτος; Lat. anus.) The subgeneric name applied by Illiger to the *Agouti* and *Acouchi*, which before were included in the great genus *Cavia* of Linnæus.

DA'SYPUS. (Gr. δασυς, and πους, *a foot*.) A name originally and very appropriately applied by the Greeks to the hare, but transferred by Linnæus to the genus including the Armadillos. This genus is subdivided in modern systems into *Dasypus* proper, *Tatusia*, and *Priodon*. The remains of a gigantic extinct animal of the armadillo kind has recently been discovered in South America, and called *Glyptodon*. See that word.

DA'SYURE. (Gr. δασυς, and ουρα, *a tail; hairy-tailed*.) The name of a genus of Carnivorous Marsupials, comprehending those which have hairy tails combined with digitigrade feet, and a dental formula of—incisores $\frac{8}{6}$, canini $\frac{2}{2}$, molares spurii $\frac{4}{4}$, molares veri $\frac{8}{8} = 42$.

DA'TA. (Lat. *things given*.) A term used in geometry to denote certain things or quantities determined by the conditions of the problem, and at the same time known or assignable. According to Simson (Preface to *Euclid's Data*), a thing is said in general to be given which is either actually exhibited or can be found out;

that is, which is either known by hypothesis or can be demonstrated to be known; so that in the analysis or investigation of a problem, from the things that are laid down to be known or given, by the help of known propositions other things are demonstrated to be given, and from these other things are again shown to be given, and so on, until that which was proposed to be found out in the problem is demonstrated to be given. When this is done the problem is solved, and its composition is made and derived from the compositions of the data which were made use of in the analysis.

In the language of the ancient mathematicians, geometrical quantities are given in *species*, *magnitude*, or *position*. Thus, a triangle is given in *species* when its three angles, or the ratios of its sides, are known. A straight line is given in *magnitude* when we know its length, or the area of a triangle of which the three sides are given. And lastly, a line is given in *position* when we know its inclination to another given line. The *Book of Data*, ascribed to Euclid, is the first in order of the ancient treatises on the geometrical analysis. There are numerous editions of this work. Those of Simson and Horsley are the best.

DATE. In Diplomatics, the notation of the time and place of the delivery or subscription of an instrument. The word is derived from the common formula at the foot of instruments, "datum" or "data," *given* at such a place and time. Dates of time are distinguished into definite and indefinite. The former mark specially the year, and sometimes the month, day, &c.; the latter only contain a general reference to some period of time. Thus many instruments of the earlier part of the middle ages are dated only "*Regnante Domino nostro Jesu Christo;*" and very often the date contained only mention of the reigning prince, without reference to the years of his reign. Definite dates are various in ancient charters and deeds. The Christian Greeks dated generally, down to the fall of Constantinople, by the year of the world; beginning their year at the 1st of September. The date used in the oldest Latin charters is commonly that of the Indiction (*see* INDICTION), which is also frequently added in the Greek. The Christian era (under the several names of year of grace, of the incarnation, of the reign of Christ, of the nativity, &c. &c.) began to be in common usage in royal charters in France about the reign of Hugh Capet; in Spain and Portugal not until the 13th and 14th centuries. In England, the Saxon kings frequently dated by the incarnation; but deeds and charters under the Plantagenet kings generally bear the year of the reigning prince.

DA'THOLITE, or DATOLITE. A mineral composed of silica, lime, and boracic acid; a borosilicate of lime. It occurs in Norway, in the Tyrol, and in the Hartz. It becomes opaque when heated.

DA'TIVE CASE. (Lat. dativus, from do, *I give.*) That inflexion of a noun which denotes participation in the action of the verb which accompanies it. *See* GRAMMAR.

DATU'RIA. The poisonous principle of the *Datura stramonium.* It belongs to the class of crystallizable alkaloids.

DAU'PHIN. The well-known title of the heir apparent to the crown of France, before the Revolution, was that of the counts or lords of Vienne in Dauphiné, from the 12th century, or an earlier period: its origin cannot be ascertained. From the last male of that ancient house the title passed to his heirs, the house of Burgundy; and from them to the family of La Tour Dupin, of whom Humbert II. surrendered his principality in 1349 to Charles, grandson of Philip of Valois: from which period the principality of Dauphiné continued to be the apanage, and the title of Dauphin the appellation, of the king's eldest son. The name of the province is derived from the title of its lords.

DA'VIT. A piece of timber used in managing the anchor.

DA'VITE. A name given to a fibrous sulphate of alumina found in a warm spring near Bogota, in Columbia.

DAVY'NE. A white or brown crystallized mineral found in cavities of some of the lapideous masses ejected by Vesuvius.

DAY (Lat. dies; Germ. tag.), in its most common acceptation, denotes the interval of time during which the sun remains above the horizon; and is opposed to *night*, which denotes the time the sun is below the horizon. In this sense it is sometimes called the *artificial day*. But the term day is also generally used to denote the time in which the earth makes a complete revolution with respect to the celestial bodies, and consequently expresses different intervals, according as the body with which the earth's rotation is compared is fixed or moveable.

The *Astronomical* or *Solar Day*, called also the *Apparent Day*, is the time that elapses between two consecutive returns of the same terrestrial meridian to the centre of the sun. Astronomical days are not of equal length, for two reasons: 1st, the unequal velocity of the earth in its orbit, in consequence of which the apparent daily motion of the sun is greater in winter than in summer; and 2d, the obliquity of the ecliptic, in consequence of which the sun's apparent daily motion in right ascension (that is, in the plane of the earth's equator) is less at the equinoxes than at the tropics. The astronomical day commences at noon, and is counted on, through the 24 hours, to the noon following.

The *Civil Day*, or *Mean Solar Day*, is the time employed by the earth in revolving on its axis, as compared with the sun, supposed to move at a *mean* rate in its orbit, and to make 365·2425 revolutions in a mean Gregorian year. In this mode of reckoning time, the days are all of the same length; and noon, or any given hour of the civil day, sometimes precedes and sometimes comes after apparent noon, or the corresponding hour of the astronomical day. Most nations, at least in modern times, have agreed in placing the commencement and termination of the civil day at mean midnight.

The *Sidereal Day* is the time that elapses between two successive culminations of the same star. This interval of time has always remained of the same invariable length, as is proved by the most ancient astronomical observations. It is divided into 24 sidereal hours; and these are again subdivided into sidereal minutes and seconds. This mode of reckoning time, during the day, is now universally adopted by astronomers in their observatories; although the commencement of the day is still determined by the apparent culmination of the sun.

DE'ACON. (Gr. *διακονος, a minister or servant.*) A minister of religion, holding, in Protestant churches, the lowest degree in holy orders. The first appointment of deacons is mentioned in Acts vi., where the Apostles direct the congregation to look out seven men of honest report, upon whom they may lay their hands. Their office at this time seems to have been chiefly the care of the poor and the distribution of the bread and wine in the love feasts. We learn, however, from the example of Philip, Acts viii., that they also had authority to preach. In the English church it is customary to require a candidate for deacon's orders to have completed his 23d year. As a deacon he is not capable of holding any benefice, and may only officiate as a curate, chaplain, or lecturer. It is generally understood that a deacon may not read the Absolution: he may not administer the sacrament alone, but in assisting the priest may offer the cup to the communicants.

DEAD BEAT. In Clock-work (called also *dead scapement*, or *scapement of repose*), a peculiar kind of scapement invented by Mr. George Graham about the year 1700, with a view to lessen the effect of the wheel work on the motion of the pendulum; and acquired its name from the circumstance that the seconds' index stands still after each drop, whereas the index of a clock with a *recoiling* scapement is always in motion, hobbling backward and forward. *See* HOROLOGY.

DEAD LIGHTS. Strong wooden posts or shutters put over the glass windows of the cabin in bad weather, as a defence against the sea.

DEAD RECKONING. A term used in navigation to express the estimation that is made of a ship's place without having recourse to observation of the celestial bodies. It is made by observing the way she makes by the log, and the course on which she has been steered, making allowance for drift, leeway, &c.

DEAD WATER. The water that closes in with a ship's stern.

DEA'FNESS. An imperfection of the sense of hearing, arising from a variety of causes, some of which are inexplicable and incurable, and others ascertainable and susceptible of relief or entire removal. When the organ of hearing is imperfect in its functions, either at birth or in childhood, dumbness or imperfect articulation attends it; for speech is an imitative faculty, and an infant born deaf, cannot attempt those motions of the organs of voice which gradually attain perfection by practice: he consequently becomes incapable of communicating his ideas through that medium.

The external ear, though tending by its form and situation to improve and perfect the sense of hearing, is in no way necessary; for it may be cut off without producing deafness. A common cause of deafness arises out of imperfections or obstructions in the passage leading from the external ear down to the membrane of the tympanum. This passage is partly cartilaginous and partly bony; and from its oblique direction it is difficult so to see into it as to ascertain the seat or cause of the obstruction. In some persons, however, when placed in a proper position, so that the sunshine or other strong light may be properly directed into it, a little management enables us to examine nearly its whole extent. In some cases of congenital deafness this passage is closed by a membrane, which, if near the external orifice, is easily detected, and may be divided or removed; but, if deeply seated, it may escape observation till the child attains a certain age, or should begin to talk: for till that time the deafness of infants often passes unobserved. Under these circumstances, and where the malformation exists in both ears,

the child will be dumb as well as deaf; for although the organs of speech may be perfect, if those of hearing are inert he is incapable of imitating sounds: in this case, therefore, a timely operation may effect the double benefit of giving both hearing and speech. Where the passage to the tympanum is more extensively obliterated or malformed, the cases become of course more complicated, but yet often admit of entire cure by a skilful and timely operation.

The presence of foreign bodies in the aural passage is a common cause of imperfect hearing, and sometimes it is obstructed by accumulations of hardened wax. These causes of deafness may in most cases be relieved or removed by syringing the ear with warm water, which should be forcibly injected, and so directed as to reach the membrana tympani. Insects or worms in the ear may be washed out in the same way, or killed by the introduction of a few drops of olive oil, or of camphorated oil.

Another cause of deafness is deficient secretion of wax, occasioning a dryness of the tube of the ear. It is relieved by greasy applications, and by the cautious use of stimulants, such as olive oil, to which a few drops of oil. of turpentine, or of compound camphor liniment, or of spirit of ammonia, have been added.

In cases of inflammation of the tympanum followed by suppuration, more or less deafness ensues, dependent upon the extent of the mischief going on, and requiring prompt, and generally antiphlogistic treatment: the pain, especially at the outset of the disorder, is often intense, and the discharge purulent and often offensive.

Lastly, hardness of hearing often appears to depend upon imperfection in the functions of the auditory nerve, and from obstructions in the Eustachian tube. The deafness that attends a violent cold is frequently dependent upon the latter cause, and goes off as the secretions of the part return to their natural state.

DEAL. (Sax. delan, *to divide.*) In Architecture, the small thicknesses of timber into which a piece of timber of any sort is cut up; but the term is now improperly restricted in its signification to the wood of the fir tree cut up into thicknesses in the countries whence deals are imported, — viz. Christiana, Dantzic, &c. Their usual thickness is three inches, and their width nine. They are purchased by the hundred, which contains 120 deals, be their thickness what it may, and reduced by calculation to a standard thickness of one inch and a half, and a length of twelve feet. *Whole deal* is that which is one inch and a quarter thick, and *slit deal* is half that thickness.

DEAN. (Lat. decanus.) An ecclesiastical dignitary in cathedral and collegiate churches, being the head of the chapter of canons or prebendaries, and forming together with them a council to advise the bishop in the affairs of his see. (*See* CHAPTER.) In England there are, properly speaking, three classes of ecclesiastical presidencies to which the title dean belongs; deans rural, deans of cathedrals, and deans in peculiars. Rural deans were originally beneficed clergymen appointed by the bishop to exercise a certain jurisdiction in districts of his diocese remote from his personal superintendence. They seem to have been equivalent in many respects to the chorepiscopi of the early church, and many parts of their office are now discharged by the archdeacons. By degrees this office fell into disuse; and though rural deans are still occasionally employed in visitations, to examine into the state of repair of churches, and performance of divine service, their functions have for many years become almost obsolete. Deans of cathedrals have already been noticed. The third species of deans, or deans in peculiar, are those of "particular parishes and churches, or rural districts that have jurisdiction within themselves, and are not under the ordinary of the diocese." These peculiars are of different kinds; and their functions consist sometimes of jurisdiction united to spiritual cure, as the dean of Battel in Sussex, and sometimes of jurisdiction only, as in the case of the Dean of the Arches, London.

DEATH WATCH. *See* ANOBIUM.

DE'BACLE. (Fr. debacler, *to unbar.*) A rush of waters, breaking down all opposing barriers, and carrying away and dispersing the broken fragments of rocks.

DEBE'NTURE. A custom-house certificate entitling the exporter of goods to a drawback or bounty. Also, an instrument in use in some government departments, by which government is charged to pay to a creditor or his assigns the sum found due on auditing his accounts.

DEBRI'S. (Fr.) In Geology, the fragments of rocks, &c.

DEBT, in Law, is a species of contract, whereby a *chose in action*, or right to a certain sum of money, is mutually acquired and lost: usually divided into debts of record, debts by special contract, and debts by simple contract. A debt of record is a sum which appears to be due, by the evidence of a court of record; such as debt on judgment or recognizance. Debt by specialty is where a sum is acknowledged to be due, or becomes due, by instrument under seal; such as a covenant, bond, &c. Both these species of debts, being contracted by a man or himself and his heirs, attach on his lands and tenements, and bind them in the hands of his heir or devisee. Debt by simple contract is either by parole or by written obligation unsealed; within which class fall bills of exchange and promissory notes.

DEBT is also a personal action of contract, in which the plaintiff seeks the recovery of a debt; *i. e.* a *liquidated* or certain sum of money alleged to be due to him. *See* ACTION.

DEBT, NATIONAL. *See* NATIONAL DEBT.

DEBUT (Fr.), in its most general acceptation, is applied to the commencement of any undertaking, or to the first step made in a public career; but it is confined more particularly to the language of the theatre, in which it signifies the first appearance of an actor, or his first appearance on any particular stage.

DE'CADE. (Lat. decas, from Gr. δεκα, *ten.*) A word used by some old writers in a general sense for the number ten, or an enumeration by tens; but more peculiarly appropriated to the number of books into which the history of the Roman Empire by Livy is divided, each division consisting of ten books or *decades*. It was also the name given to the space of ten days, which in the French republican calendar was substituted for the ordinary week. The tenth or last day was termed *decadi*. Thus, except in bissextile years, the whole number of decades was thirty-six and a half: the days of the half decades, falling at the close of the year, were at one time called *sansculottides*, and afterwards *complementary;* and dedicated respectively to Virtue, Genius, Labour, Opinion, and Recompence.

DE'CAGON. (Gr. δεκα, *ten*, and γωνια, *an angle.*) A geometrical figure, having ten sides and ten angles. If the sides and angles are all equal, the figure is a regular decagon, and inscribable in a circle. Euclid, in the Fourth Book of his *Elements*, shows that the side of a regular decagon is equal to the greater segment of the radius of the circumscribing circle divided by a medial section, or so that the rectangle contained by the whole radius and one of the parts is equal to the square of the other part; consequently, if we denote the radius by r, and the side of the decagon by s, we shall have the proportion $r : s :: s : r - s$; whence $s^2 + rs = r^2$, and by solving the quadratic $s = \frac{1}{2} \cdot r\,(\sqrt{5} - 1)$. If the radius is unit, $s = \frac{1}{2} \cdot (\sqrt{5} - 1) = \cdot 618034$; and the area $= 7 \cdot 694209 \times s^2$, or 7·694209 of the square of the side.

DE'CALOGUE. (Gr. δεκα, *ten*, and λογος, *discourse* or *catalogue.*) The commandments which were delivered by God to Moses upon Mount Sinai (Exod. xx.) That their number was understood by the Jews to be ten appears from Exod. xxxiv. 28.; but they differed from us in the manner of dividing them, considering our two first as one, and separating the last into two. The same method is adopted by the Romish church, professing to follow the authority of St. Augustine. (See *Catechism. ad Parochos.*)

DE'CA'MERON. (Gr. δεκα, *ten*, and ἡμερα, *day.*) The name given by Boccaccio to his celebrated collection of tales: they are supposed to be narrated in turn, during ten days, by a party of guests assembled at a villa in the country to escape from the plague which raged at Florence in 1348.

DECA'NDROUS. (Gr. δεκα, and ανηρ, *a male.*) A plant having ten stamens.

DECANTA'TION. The pouring off a clear liquid from its subsidence or residue; it is often resorted to in the chemical laboratory instead of filtration, the clear supernatant liquor being poured or syphoned off from precipitates, which may thus be repeatedly washed or edulcorated, so, as to free them from all soluble matters.

DECAPITA'TION. (Lat. decapitare, *to behead.*) A mode of punishment of great antiquity, having been practised by the Jews, Greeks, and Romans, and some other ancient nations. Among the Continental nations of modern times, it has long been the ordinary punishment inflicted on all capitally convicted criminals. During the early period of English history, it was the usual mode of punishing felons; but it afterwards became a punishment appropriated only to criminals of the highest rank, and even to this day it is considered as the most honourable death which a capital offender can undergo. The last instance of the infliction of this punishment in England occurred in 1745, soon after the rebellion in Scotland had been quelled.

DE'CAPOD, *Decapoda.* (Gr. δεκα, and πους, *a foot; ten-footed.*) A name applied by Dr. Leach to a tribe of Cephalopods, including those which have ten locomotive and prehensile appendages proceeding from the head; two of which are always longer than the rest, and are called tentacles. Also applied by Cuvier to designate an order of Crustaceans, comprehending those which have ten thoracic feet.

DECA'PTERY'GIANS, *Decapterygia.* (Gr. δεκα, *ten*, and πτερυξ, *pinion.*) A name given by Schneider to an artificial division of fishes, including those which have ten fins.

DE'CARBONIZATION OF CAST IRON. This process is resorted to in order to convert cast iron into

steel, or by a further decarbonization to reduce it to the state of malleable iron; hence, many articles which were formerly exclusively manufactured of wrought iron are now cast, and afterwards decarbonized, such as horse-shoes, &c.; and in other cases various cutting instruments are cast, and afterwards brought to a proper hardness by a similar process. The articles to be decarbonized are packed in finely powdered hæmatite, or native oxide of iron, and exposed for a sufficient time to a high red heat. It is often necessary to mix iron filings or turnings with the hæmatite: these substances, thus applied, gradually abstract the excess of carbon in cast iron, and reduce it to a state analogous to that of steel; or, by a longer continuance of heat, to that of soft iron. In some cases, however, the process seems rather to affect the texture and mechanical properties than the composition of the iron, and is therefore more analogous to annealing.

DE'CASTYLE. (Gr. δεκα, *ten*, and στυλος, *a column.*) In Architecture, a building having ten columns on a front or flank.

DE'CASYLLA'BIC, having ten syllables. In the German and English languages the ordinary heroic verse is decasyllabic; but a short syllable is sometimes added at the end by way of variety, and this, in consequence of the structure of those languages, takes place more frequently in the former than the latter. In the Italian heroic verse the eleventh syllable is almost uniformly added, and hence it is more properly to be termed an *hendecasyllabic*. In French versification the decasyllabic line is appropriated to light compositions, especially tales.

DECE'MBER (Lat. decem, *ten*), was the tenth month in the calendar of the ancient Romans, who began the year with March.

DECE'MVIRI. (Lat. *ten men.*) Properly any body of ten men appointed for particular purposes. But that which is especially known by this name was the commission elected from the Roman patricians in the 302d year after the foundation of the city, and invested with all the supreme powers of the state, for the purpose of drawing up a body of laws founded, according to Roman tradition, on the most approved institutions of Greece. They presented to the people a number of laws engraved on ten tables, containing a summary of the privileges to be enjoyed by the people, and the crimes to be punished, &c. At the same time they informed the people that their plan was incomplete; and accordingly a new commission, to which the plebeians were admitted, was appointed for the next year, with the same powers; the result of which was the addition of two more tables to the former ten, thus making up the famous twelve tables, which were the foundation of all Roman law in subsequent times. The second decemvirate did not demean itself with the same moderation as the first, but sought to prolong its power, and at the same time proceeded to some violent acts of despotism, which so exasperated the people as to make its dissolution necessary.

Besides these extraordinary commissions, there was a body of decemviri chosen for judicial purposes, to preside over and summon the centumviri, and to judge certain causes by themselves. There were likewise decemviri appointed from time to time to divide lands among the military.

DECE'PTIVE CA'DENCE. In Music, a cadence in which the final close is avoided by varying the final chord.

DECI'DUOUS. (Lat. decido, *I fall off.*) In Zoology, a term applied to parts which have but a temporary existence, and are shed during the life-time of the animal, as certain kinds of hair, horns, and teeth.

Deci'duous is applied, in Botany, to plants whose leaves fall off in the autumn, in contradistinction to evergreens.

DE'CIMAL ARI'THMETIC, is the common system of arithmetic, in which the scale of numbers proceeds by tens. *See* Arithmetic.

DE'CIMAL FRACTIONS, are fractions which have for their denominator 10, 100, 1000, &c., or in general some power of 10. The use of decimal fractions is merely an extension of the ordinary scale of arithmetical notation. Setting out from the unit's place, the first figure to the left (in the expression of any whole number) denotes so many tens, the second to the left so many hundreds, the third so many thousands, and so on; so that in the number 765, for example, each unit of the 6 is the tenth part of each unit of the 7, and each unit of the 5 a tenth of each unit of the 6. In like manner, in the expression of a decimal fraction, setting out from the unit's place, the first figure to the right expresses so many tenth parts, the second to the right so many hundredth parts, the third so many thousandths, and so on; so that each figure, as before, expresses parts, which are each ten times smaller than those expressed by the figure immediately preceding. By expressing fractions in this manner, the operations of addition, subtraction, multiplication, and division are exactly the same as in integer numbers.

In order to distinguish the integral from the fractional part of a numerical expression, a point or comma is placed between them. Various marks have been used for this purpose at different times; but the point is now most commonly employed, and, according to the practice of Sir Isaac Newton, it should always be placed near the top of the figure, thus 2·46, which prevents it from being confounded with the ordinary marks of punctuation.

Decimal fractions appear to have been introduced by Regiomontanus, about the year 1464; but Stevinus was the first who wrote an express treatise on the subject in his *Practique d'Arithmetique*, published in 1582. They are now universally employed in all arithmetical calculations; and it is much to be regretted that a decimal division of weights, measures, money, &c. has not been adopted in all civilized countries, by which the reduction of fractional parts from one scale to another would be obviated, and all the applications of arithmetic to the ordinary purposes of life greatly simplified. A subdivision of weights and measures on this principle was adopted in France at the time of the Revolution, but has not been imitated by other countries.

DECIMA'TION. (Lat.) In Roman History, the selection by lot of one man out of every ten, who was put to death as an example to, or satisfaction for, the rest. If an army, legion, or century, as the case might happen, had quitted its post, raised a mutiny in the camp, or otherwise failed in its duty, it was assembled before the general; the lots were cast into an urn; as many were drawn as formed the tenth part of the number of the offenders, and the unlucky drawers were put to the sword. This practice has been occasionally recurred to in modern times; as by the Spanish general Cuesta, after the battle of Talavera.

DECLAMA'TION (Lat. declamatio), signified, among the ancients, the art of speaking indifferently upon both sides of a question: a species of intellectual exercise resorted to by the rhetoricians of Greece and Rome, as the best means of acquiring facility in public speaking. In modern times the meaning of *declamation* is different in different countries. In Germany, and in most parts of the Continent, it is often used in a sense nearly synonymous with *recitative*. In France and England, especially the latter, it is sometimes applied to any grand oratorical display, either in the pulpit, at the bar, in the senate, or on the stage, in which the voice, gesticulation, and the whole delivery of the speaker are in perfect keeping with the subject matter of his address. But it is employed most usually in a disparaging sense, to indicate the use of forced emphasis, inflated language, and violent gestures to withdraw the attention of the auditors from the weakness or fallacy of the reasoning. *See* Eloquence.

The Romans employed the term *declamare* only in the sense of *to plead* or *practise at the bar*, as in the verse of Horace (*Epis*. 2. 2.), —

Dum tu declamas Romæ;

but that they at the same time assiduously cultivated the art of declamation in the sense of recitation, is evident from the following couplet, in which Martial has happily illustrated the great importance of a good delivery: —

Quem recitas meus est, O Fidentine, libellus;
Sed male quum recitas, incipit esse tuus.

DECLARA'TION. In Law, a legal specification, on record, of the cause of action, by a plaintiff against a defendant. *See* Pleading.

DECLE'NSION. (Lat. declinatio, from declino, *I deflect.*) In Grammar, the changes of termination in nouns, corresponding to the various relations in which substances are conceived to stand. *See* Case and Grammar.

DECLINA'TION CI'RCLES, are small circles of the sphere, parallel to the equator, in which the stars perform their apparent diurnal revolutions.

DECLINA'TION OF A CELESTIAL BODY, is the angular distance of the body north or south from the equator, and is measured on the great circle which passes through the centre of the body and the two poles, and is consequently perpendicular to the equator. The place of a star in the heavens is determined by means of its *right ascension* and *declination*; the *right ascension* being the angular distance, measured on the equator, between the first point of Aries and the point in which the meridian of the star intersects the equator. Right ascension and declination thus correspond to longitude and latitude on the surface of the earth. In the analytical theory of the planets it is often necessary to define the place of a planet or comet with reference to the ecliptic, or plane of the earth's annual motion; and the early astronomers unfortunately adopted for this purpose the terms *longitude* and *latitude*, which, as the same terms are appropriated to terrestrial objects in a different sense, is the cause of considerable embarrassment to beginners. The student of astronomy must therefore remember that in speaking of celestial objects, declination and right ascension have

reference to the *equinoctial*, or plane of the earth's diurnal rotation; while *latitude* and *longitude* refer to the *ecliptic*.

The declination of a star is said to be *north* when the star is north of the equator, and *south* when the star is south of the equator.

DECLINA'TION OF THE MAGNETIC NEEDLE. The axis of a magnetic needle, that is, the straight line which joins its poles, does not coincide with the astronomical meridian, but deviates from it more or less, sometimes towards the west, and sometimes towards the east. This deviation is called the *Declination of the Needle*.

It was formerly imagined that the magnetic needle, when freely suspended, took a direction exactly north and south at all places on the earth; and Columbus is said to have been greatly astonished when he observed, in his memorable voyage for the disoovery of the New World, in 1492, that the needle of his compass did not point to the true north. The same fact was observed by Sebastian Cabot about the year 1500; but notwithstanding its great importance to mariners, the first tables showing the amount of the declination at various places were only prepared in 1599 by the Dutch navigators at the orders of the Prince of Nassau. In 1622, Gunter, professor of geometry at Gresham College, made the important discovery that the declination is not constant. He found it to be 6° 13′ to the east at London in that year; whereas in 1580 it had been observed by Robert Norman to be 11° 15′ also to the east.

The following table of observations, made at Paris, will be sufficient to give an idea of the changes which the declination of the needle has undergone at different epochs:—

Years.	Declination.	Years.	Declination.
1580	11° 30′ East.	1805	22° 5′ West.
1618	8 0	1813	22 28
1663	0 0	1814	22 34
1678	1 30 West.	1817	22 19
1700	8 10	1819	22 29
1767	19 16	1822	22 11
1780	19 55	1824	22 23
1785	22 0	1825	22 22

From this table it appears that since 1580 the declination has varied more than thirty degrees. In 1663 it vanished. From the date of the first observations till 1820, it has advanced progressively westward; but since that time it appears to have assumed a retrograde movement towards the east. (*Pouillet, Elemens de Physique*, t. i. p. 462.)

DECOLLA'TION. (Lat. de, *off*, and collum, *the neck*.) A word synonymous with *beheading;* used chiefly in reference to the decapitation of John the Baptist, to the festival instituted by the Romish church in his honour, and to the celebrated picture of Mabuse (*Walpole's Anecdotes of Painting*, vol. i. p. 82.), which represents this subject. This word is used by Fabyan so far back as the year 1350.

DECOMPOSITION, CHEMICAL. When compounds are resolved into their elements, or when the chemical constitution of substances is altered, they are said to be decomposed; and when, in this operation, new products are formed, such products are called the *results of decomposition*. Thus, *ammonia* is the result of the decomposition of most animal substances; *carburetted hydrogen gas* is the result of the decomposition of pit-coal, &c.

Chemists use the terms *simple* and *compound*, or *single* and *double* decomposition, to distinguish between the less and more complicated cases. When a compound of two substances is decomposed by the intervention of a third, which is itself simple, or which acts as such, the case is one of simple decomposition: water, for instance, is a compound of oxygen and hydrogen. When the metal potassium, which is a simple body, is thrown into it, it is decomposed; the hydrogen is liberated in the form of gas, and the oxygen combines with the potassium to form potassa. Such a case is often tabularly represented as follows; and the annexed numbers are the *equivalents* of the acting bodies, or the respective weights which are required for perfect decomposition.

Water 9. { Hydrogen 1.
Oxygen 8 + potassium 40. }

Potassa 48.

This shows that when 9 parts by weight of water are decomposed by 40 parts of potassium, 48 parts of potassa (or oxide of potassium) are formed, and 1 part of hydrogen liberated.

When two new compounds are produced, the result is called *double* or *complex* decomposition. Thus, when potassa (composed of potassium and oxygen) and hydrochloric acid (composed of hydrogen and chlorine) react upon each other, chloride of potassium (composed of chlorine and potassium) and water (composed of hydrogen and oxygen) are the results. These, with their respective *equivalents*, are shown in the following diagram.

Water 9.

Hydrochloric acid 37. { Hydrogen 1 + oxygen 8.
Chlorine 36 + potassium 40. } Potassa 48.

Chloride of potassium 76.

This table, therefore, shows that 37 parts by weight of hydrochloric acid and 48 of potassa produce, by mutual decomposition, 76 parts of chloride of potassium and 9 of water.

A knowledge of the mutual decomposing powers of different substances, or, in other words, of their relative affinities, constitutes the skill of the practical chemist. See in reference to this subject the articles AFFINITY, EQUIVALENTS, and the general article on CHEMISTRY.

DECO'MPOSI'TION OF FORCES. In Mechanics, signifies the same thing as the *Revolution of Forces*. Any force whatever may always be decomposed or resolved into several others, the resultant of which is equal to the given force. For example, a force represented in intensity and direction by the diagonal of a parallelogram, may be resolved into two others of which the intensities and directions are respectively represented by the sides of the same parallelogram. *See* COMPOSITION OF FORCES.

DECO'MPOSI'TION OF LIGHT. The separation of a beam of light into the different rays which exhibit the prismatic colours. *See* LIGHT.

DE'CORATION. (Lat. decorare, *to adorn*.) In the Fine Arts, adornment, ornament, embellishment. It is a combination of ornamental objects, which a desire for variety brings together in all sorts of forms for embellishing those subjects which are the objects of art. The decoration of any work should be confined strictly to the development of impressions which the mass itself is intended to create; its object being merely to multiply the relations it has, by presenting new images which spring from the original bare design. Decoration in all the arts, except on particular occasions, should be used with a sparing hand. Once commenced it becomes difficult to know when to cease.

DECOY. A device by which aquatic birds, chiefly ducks, are enticed from a river or lake, up a narrow winding canal or ditch, which, gradually becoming narrower, at last terminates under a cover of net work of several yards in length. The birds are enticed by the smoothness of the turf on the margin of the canal, which tempts them to leave the water, and begin to dress their plumage. When so engaged at some distance up the canal, they are suddenly surprised by the decoy man and his dogs, who have been concealed behind a fence of reeds; and having again taken the water, they are driven up by the dogs till they enter within the net work which terminates the decoy, and are then readily caught.

DECRE'E, *Decretals*. (Lat. decerno, *I decide*.) Decreta or decrees, in the Civil Law, are the decisions of emperors on cases submitted to them, forming a part of their constitutions. Decretals were the decrees of popes, having the same authority in canon law as decrees in civil. They retained this authority in most Catholic countries until the 14th century. Several compilations of them are in existence. The false decretals of Isidore, a spurious collection framed with a view to extend the papal power, profess to contain the decrees of popes during the first three centuries: they were forged in the 9th.

DECREE. In Law, the judgment of a court of equity on any bill preferred. Either party may petition the court for a re-hearing, before it is signed and enrolled. After that form has been gone through, a bill of review may be had upon apparent error in judgment on the face of the decree. It may also be appealed against in the House of Lords. In Scottish law, various legal judgments and sentences are styled *decreets*.

DE'CREMENT. (Lat. decresco, *I decrease*.) The small part by which a variable quantity becomes less and less. It is opposed to *increment;* but these terms are now seldom used by mathematicians.

DECRE'PITATION. (Lat. decrepito, *I crackle*.) The crackling noise which common salt and many other substances make when thrown into the fire.

DECU'RION. The Latin name for the commander of ten men. A military decurion was a cavalry officer, who originally commanded ten soldiers, or one third of a turma; but afterwards the same name was preserved, though the command was extended to the whole turma. Municipal decurions were magistrates in the municipal towns, answering to senators at Rome. In later times also certain officers of the imperial household used this title; as decurions of the chamberlains, &c.

DECUSSA'TUS, *Decussate*. Applied to the arrangement of bodies in pairs that alternately cross each other; as the leaves of many plants.

DEDICA'TION. (Lat.) In Literature, a complimentary address to a particular person, prefixed by an author to his work. Dedications arose out of the dependent situation in which authors have too frequently been placed in reference to their powerful or wealthy patrons; and, at no very distant time, were often rewarded by pecuniary presents. The custom of dedicating works was in use at a very early period. The brightest ornaments of Roman literature, Horace, Virgil, Cicero, and Lucretius, were among the number of those who practised it. At the period of the revival of letters in Europe, few works were published without dedications; many of which are remarkable for their elegance and purity of style, and from the interesting matter which they contain are of far more value than the treatises to which they are prefixed. But the practice became gradually perverted; and many of the authors of the succeeding generations employed them chiefly with the view of securing the patronage of the great. Dedications were most abused in France under Louis XIV., and in England from 1670 to the accession of George III. Dryden was a great dedicator, and Johnson wrote dedications for money. Corneille got 1000 louis d'ors for the dedication of *Cinna*. Some of the most beautiful dedications with which we are acquainted are those prefixed to the different volumes of the *Spectator*, by Addison; and in more recent times the poetical dedications with which each canto of Sir Walter Scott's *Marmion* is prefaced. A complete history of dedications would prove a valuable accession to modern literature, as they would throw a flood of light upon the history, character, and attainments of many distinguished persons which are now involved in obscurity. A few such works are in existence; but they are only accessible to the learned. See *De Dedica. Lib. vet. Lat.* by Walch. (Leip. 1715.) *Commenta. de Dedica. Lib.* by Tacke. (Wolfenbüttel, 1733.)

DE'DIMUS POTESTA'TEM. In Law, a writ or commission given to one or more private persons, for the speeding an act appertaining to a judge or some court. When the commission of the peace is renewed, a writ of dedimus potestatem is issued out of chancery, directed to some ancient justice, to swear in a justice newly inserted.

DEED. A deed, in Law, is a writing sealed and delivered by the parties. If made by one party only, it is termed a deed poll; if by several, an indenture. The formal parts of a deed of conveyance are, first, the date and names of the parties; secondly, the recitals, in which the intention of the parties and former transactions with reference to the same property are recounted, so far as necessary; then the operative part. This expresses, first, the consideration for which the deed is made (which for many sorts of deeds is now merely nominal); then the conveyance by and to the several parties; then the parcels, or description of the tenements and their legal adjuncts; then what is termed the habendum, beginning with the words "to have and to hold," expressing the quantity of estate conveyed; then the declaration of uses, which limits or modifies the enjoyment to one or more parties, according to the stipulations previously made; then the declarations of trusts, if any, that is, of equitable interests created in the property; and lastly, the covenants for title. These covenants stand in the place of the ancient warranty, a clause by which the grantor warranted and secured to the grantee the thing granted; arising out of the feudal custom, whereby if a lord had thus warranted a fief, and the tenant was afterwards evicted, the lord was bound to recompense him with another fief of equal value. The covenants relating to the title secure to the grantee a pecuniary compensation for any damage he may suffer contrary to their stipulations. Besides the covenants for title, such as may be demanded by the peculiar circumstances of the case, — as in a lease the covenants for repairing, payment of rent, &c., — covenants in general, when broken, give the covenantee an action for damages against the covenantor; or if he be dead, against his executor or administrators to the extent of his personal property in their hands; or if the covenant be with him, his heirs and assigns, the remedy extends to the heir or grantee of the covenantee.

Lastly, the conclusion of a deed contains its execution and date. It must be signed and sealed by the grantor; and also by the grantee, if any engagement or covenant is entered into by him. It is usual for witnesses to attest the deed; but this is not necessary, unless where a power having been given to be executed by deed the terms of the power require such attestation. There are several species of deeds; some having effect at common law, others under the Statute of Uses; some creating an estate termed original or primary; some enlarging, restraining, transferring, or extinguishing estates already created, which are called secondary or derivative.

DEER. The English generic name for the ruminating quadrupeds with deciduous horns, or antlers; which appendages form, in fact, the essential character of the genus *Cervus* of Linnæus. (*See* CORNUA.) Deer are anatomically distinguished from other ruminants by the absence of a gall bladder

The species of deer may be primarily divided into two groups, of which one includes those with antlers more or less flattened, the other those with rounded antlers. The elk (*Cervus alces, L.*) is the most characteristic species of the first group, and forms the type of the subgenus *Alces* of modern systems. It equals or exceeds the horse in bulk; has a short body, with a still shorter neck, raised on long stilt-like legs. The muzzle is long, broad, and overhangs the mouth like a square-shaped lapel: it is very muscular, and is of essential service to the animal in detaching the lichens and mosses from the trunks of trees and other places within its easy reach. The long legs of the elk particularly adapt it to the marshy and swampy forests which it chiefly frequents, in the northern parts of both the European and American continents. The antlers of the elk appear first in the form of *dags* or unbranched pointed stems; these are succeeded by a stem or *beam* supporting a few short branches. At five years he puts up antlers in the form of a triangular plate, supported on a pedicle, and notched along the outer margin. Afterwards the bony plate increases in its expanse, and the points between the notches are developed into long branches or *snags*, of which a single antler sometimes sends off as many as fourteen; and the pair will then weigh about fifty pounds. The female elk goes with young rather longer than eight months.

The rein-deer (*Cervus tarandus*) differs from the rest of the genus in the presence of antlers in both sexes, and in the great development of the *brow-antlers*, or branches which extend forwards over the forehead from the base of the beam. The antlers are retained through the winter; and, as it is understood that the brow-antlers are used to detach the frozen snow, which at that season covers the *lichen rangiferinus*, and other species on which the rein-deer feeds, the necessity of the singular exception in favour of the female rein-deer becomes obvious. Her antlers are, however, always smaller than those of the male. The rut takes place in mid-winter, and the period of gestation is about six months: as in most other species of deer, one fawn is produced at a birth. The rein-deer is a native of the most northern parts of Europe and America. To the Laplander it serves all the ordinary offices of the beast of draught, and supplies him with the rich variety of nutriment, clothing, and useful implements, which man in more favoured climes obtains from other species of the valuable order of Ruminantia.

The third species of deer referable to the flat-horned group is that which the ancients termed *platiceros*, and which now forms the ornament of the English park; the fallow deer (*Cervus damas*, Linn.). In the technical language of the hunter, the male fallow deer is called a "buck," the female a "doe," and the young a "fawn." The buck-fawn of the second year, which is characterized by having simple dags, is a "pricket." In the third year a brow-antler is put forth, and the young buck is termed a "sorel." In the fourth year he is a "sore," and the summit of the beam presents a bifid expansion. At the fifth year the expanded summit of the beam is formed, and begins to develop snags, and the fallow deer is then a "buck of the first head." At each subsequent year the branches of the expanded beam increase in length to a certain period, after which they lose their size and regularity. The period of gestation in the fallow doe is eight months.

Of the species of deer of which the beam of the antler gives a rounded form in section, the red deer (*Cervus elaphus*) and the roe-buck (*Cervus capreolus*) are indigenous species.

The male red deer, in the language of "the noble art of venerie," is called a "hart," and the female a "hind." She goes with young about a week longer than the fallow doe; and brings forth in May a single fawn, rarely two. The young of both sexes are at first styled "calves." The male differs from that of the fallow deer in putting up at six months a pair of rudimental antlers, in the form of cylindrical knobs, called "bossets." In the second year they assume the condition of "dags," and the wearer is called a "brocket." In the third year two or three branches or "tynes" are developed, and the young deer becomes a "spayad." In the fourth year the summit of the beam expands into the crown or "surroyal," and the deer is now distinguished by the name of "staggard." In the fifth year the term "stag" is applied to him in a limited and technical sense. At the sixth year he is a "hart," and his designation is not afterwards changed; but at this period he is particularly distinguished as a "hart of ten," and is not considered fair game till his seventh year, when the hart is said to be "palmed" or "crowned," in reference to the full development of his antlers. The antlers or "attire" are shed very soon after pairing; at this period, when the hart has "lost his attire," he retreats to the shadiest or most unfrequented part of his range. New antlers begin to grow very soon after the old ones are shed, and they are completed in the month of August. The skin, or "velvet," which protected the vascular periosteum during their growth now dries, and is rubbed off against trees or any resisting body;

this act is technically called "burnishing." The harts during this period form a peculiar and distinct association. The hinds form another group, and go also into retirement with their calves, to which they attend with a high degree of instinctive maternal solicitude. The "brockets," and the "brockets' sisters," constitute a third association.

The roebuck is the smallest species of European deer; the male is monogamous, and the female brings forth two fawns. In our own island they are now confined to the Scottish mountains.

The largest species of round-antlered deer in America is the *Wapiti* (*Cervus strongyloceros*); that of Asia is the great *Rusa* (*Cervus hippelaphus*), which is noticed in the writings of Aristotle. In South America there is a singular group of small deer, called prickets or brockets, on account of the antlers never being developed beyond the simple condition of "dags," such as characterize the brocket age of the red deer.

DEFÆCA'TION. (Lat. de, and fæx, *dregs*.) The separation of the dregs and impurities of liquors.

DEFAMATION. *See* LIBEL.

DEFAU'LT. (Fr. défaut.) In Law, is in a general sense the omission of any act which a party ought to do in order to entitle himself to a legal remedy. Such is, for example, non-appearance in court on a day assigned. If a plaintiff in an action make default in appearance, he is non-suited; if a defendant, judgment by default passes against him. Suffering judgment by default is taken for an admission of the contract alleged by the plaintiff.

DEFEA'SANCE. In Law—1. A collateral deed, made at the same time with a deed of conveyance, containing conditions on the performance of which the estate created by the deed of conveyance may be defeated. 2. A defeasance on a bond, recognizance, or judgment recovered, is a condition which when performed defeats a bond, &c. (*see* BOND), contained in or indorsed on the instrument itself.

DEFE'CTIVE FIFTH. In Music, an interval containing a semitone less than the perfect fifth. It is also called semidiapente, and flat, lesser, or diminished fifth.

DEFE'NDER OF THE FAITH. (Fidei Defensor.) A title bestowed on Henry VIII. of England by Pope Leo X. on the occasion of that monarch's publishing his writing against Luther. When at the Reformation Henry suppressed all the monasteries and convents in England, the pope deprived him of this title; but in the thirty-fifth year of his reign, it was confirmed by parliament, and it has been since constantly assumed by the sovereigns of England.

DE'FERENT. (Lat. defero, *I carry away*.) In the Ptolemaic system of the universe the planets move in circular orbits, the centres of which are carried round in the circumferences of other circles. These secondary circles are called the *deferents*, as carrying the orbits; those in which the planets move being the epicycles. The system of epicycles and deferents was invented by Hipparchus for the purpose of explaining the eccentricities, perigees, and apogees of the planets. *See* EPICYCLE.

DEFI'CIENT NUMBERS, in Arithmetic, are numbers such that the sum of their aliquot parts is less than the numbers themselves. Thus, 8 is a deficient number; because its aliquot parts, 1, 2, 4, when added together, make only 7. In like manner the number 16 is deficient, its parts being 1, 2, 4, 8, the sum of which is 15.

DEFILADING. *See* FORTIFICATION.

DEFI'LE. In Fortification, a narrow way, through which troops can pass only in *file*, or a small number abreast.

DE'FINITE PROPORTIONALS. In Chemistry. *See* ATOMIC THEORY and EQUIVALENTS.

DEFINI'TION (Lat.), literally laying down a boundary, signifies, in Logic, an expression which explains any term so as to separate it from every thing else, as a boundary separates fields. By the schoolmen definitions are divided into *nominal* and *real*, according to the *object accomplished* by them, whether to explain merely the meaning of the word or the nature of the thing; and, on the other hand, they are divided into accidental, physical, and logical, according to the *means employed* by each for accomplishing their respective objects, whether it be the enumeration of attributes, or of the physical or the metaphysical parts of the essence. (*Whately's Logic*, pp. 141-2.)

DEFLAGRA'TION. (Lat. deflagro, *I burn*.) A chemical term applied to sudden and rapid combustion: when a mixture of charcoal and nitre is thrown into a red hot crucible it burns with a kind of explosion, or *deflagrates*.

DEFLE'CTION OF THE RAYS OF LIGHT. When a luminous ray passes very near an opaque body it is *deflected*, or bent from its rectilinear course, towards the surface of the body, and the deflection is greater in proportion as the distance of the ray from the body is less. This phenomenon was first observed by Grimaldi, and was carefully examined by Newton, who gave it the name of *diffraction*.

DE'FTER-DAR, literally *Book-keeper*. The title given by the Turks to the chancellor of the exchequer and his two coadjutors or deputies in the finance department.

DEGLUTI'TION. (Lat. de, and glutio, *I swallow*.) In Physiology, the act of swallowing food. This operation is performed by mechanism of the most extraordinary and complicated kind, in which the consentaneous actions of the various muscles of the tongue, the soft palate, the pharynx, the larynx, and the œsophagus or gullet, are concerned, partly by voluntary and partly by involuntary impulse.

There are, as it were, four openings at the back part of the mouth, three of which, during deglutition, must be perfectly but temporarily closed; whilst the fourth, namely, that through which the food is to pass towards the stomach, must be open and without impediment. The openings which are to be closed are those which communicate with the nose, with the ears, and with the lungs; but, as far as the latter is concerned, it follows of course that respiration can only be suspended for a very short time, and that therefore the moment the morsel is swallowed, or has passed over the larynx, the communication between it and the nose must again be free.

When food is properly masticated, a sufficient quantity is collected upon the tongue, which is then so pressed against the palate by a muscular action proceeding from the tip of the tongue backwards as to propel it towards the pharynx, or upper end of the gullet; at this moment the soft palate, previously hanging like a pendulous veil at the back of the mouth, is drawn into a horizontal position, so as to form a continuation, as it were, of the bony part of the palate, and at the same time to close the nasal canals. No sooner does the portion to be swallowed reach the pharynx, than it is embraced, as it were; while the base of the tongue, the os hyoides, and the larynx are raised forward to meet it, and hurry it over the opening of the glottis towards the œsophagus. The instant the larynx is raised the glottis is firmly closed; and as soon as the morsel has passed over it the larynx descends, the epiglottis is raised, and the glottis opens again to allow air to enter the lungs. Thus it is, therefore, that the food is limited to the direction of the œsophagus, and neither passes into the nasal canals, nor into the Eustachian tubes, nor into the larynx, all the concurrent actions in this period of the act of deglutition being simultaneously and involuntarily performed. By the contraction of the pharynx the morsel is delivered into the œsophagus, and propelled by the muscular structure of that tube towards the stomach. In the upper part of the œsophagus, the fibres relax immediately after the passing of the food, but the inferior portion remains contracted for some moments after the food has entered the stomach.

The due admixture of saliva with the food, and the lubrication of the various and complicated parts over and through which the food passes, by mucous secretion, tend materially to facilitate the progress of the alimentary pellet.

DEGRE'E. A distinction of rank in universities: in its proper use denoting a certain amount of proficiency in the faculty or science of which it is entitled; but, by modern usage, frequently conferred either of right to members of the university of sufficient standing, or merely as an honorary distinction. The origin of degrees at the universities of Paris and Bologna, the two most ancient in Europe, appears to have been only the necessary distinction between those who taught and those who learnt. The former were styled (such was at least the case at Paris) doctors or teachers, and masters, as a token of respect, indiscriminately. At what time the distinction between these two degrees arose we cannot ascertain; but about the middle of the 13th century we find, at Paris, doctors and masters simply as graduates, and not necessarily connected with the business of teaching; those who were so being called regent masters, or simply regents. (*See* REGENT.) The degree of bachelor, the lowest in the several faculties, is certainly of French origin; from whence it has been argued that the whole system of academical titles is so likewise. Degrees still continue to bear the same names, and, with some variation, the same relative academical rank, in most European countries; but the mode of granting them, and their value at different universities as tokens of proficiency, vary greatly. At Oxford and Cambridge degrees are given in arts, divinity, law, medicine, and music; but among all these the lowest degree in arts, viz. that of bachelor (B. A.), is the only one conferred on a substantial examination, and the only one which is attained by proceeding through a regular academical course of study. The higher degrees in arts, and those in the other faculties, are attained simply by residence and the performance of a few unimportant exercises. Honorary degrees, in the English universities, are generally conferred in civil law.

A considerable difference of opinion exists upon the question how far the possession of degrees forms a valid test of ability to exercise any of the learned professions; and though at first sight nothing might appear more preposterous than to question the necessity of some such test being exacted from those to whom the lives and fortunes of millions of human beings are in a peculiar manner

intrusted,—physicians and lawyers, — still there are many who maintain that "degrees have always been, and must continue to be, utterly worthless." Among those who entertained this opinion may be mentioned Dr. Smith; whose sentiments on this subject, though pretty distinctly indicated in the *Wealth of Nations*, are fully detailed in a letter to Dr. Cullen, which the reader will find in Mr. M'Culloch's edition of that work, 1 vol. 8vo. But those who wish to see this question fully examined in all its bearings, should consult a note, or rather dissertation, "On the Value and proper Mode of conferring Literary and Scientific Degrees," in the same edition of the work now referred to, in which the author contends that it is not against the principle of degrees, so much as the mode of conferring them, that the chief objections may be urged. The value of a degree, it is there contended, must always depend on the disinterested character of the parties who confer it. Now, when it is remembered that, till very recently, in every university, those in whom was vested the privilege of granting degrees are the identical parties engaged in preparing the candidate for receiving them, who are thus, as it were, called upon to form an estimate of their own handiwork, it will be sufficiently obvious that the system hitherto pursued in awarding academical distinctions must be wholly inadequate as a test of literary or scientific merit. This being the case, it might seem almost unaccountable that so little success should have attended the many efforts that have been made to place the granting of degrees on a sounder and more satisfactory footing, were it not matter of notoriety that to divert into a new channel the current of popular feelings or prejudices which has been flowing for ages in a particular direction is almost impracticable, even after the benefits of the change have been clearly and unequivocally demonstrated. Some such ideas as to the inadequacy of degrees appear to have been entertained a few years ago in many of the German states. There the bare possession of a degree was formerly sufficient to authorize members of the legal or medical profession to engage in the exercise of their several duties; but a change has been since effected, which has at once infused new life into the educational establishments of the country, and has been attended with great advantage to all classes of the people. This change consists in the establishment of boards composed of gentlemen eminent for their attainments, and wholly unconnected with the business of education, whose duty it is to ascertain by a rigid examination the qualifications of those who have already obtained degrees in the faculties of law and medicine, and thus to determine whether the degree has been properly conferred; and unless the diploma obtained at the university be stamped with the authority of these different boards, the possessor of it is prohibited from engaging in the exercise of his profession. In this way the degree, which was formerly regarded as the *aim* or *end* of the student's ambition, is now looked upon simply as a *means* of attaining it, inasmuch as it confers no direct privileges, and does not necessarily secure professional honour or emolument, though it form the sole passport to both. A somewhat similar course relative to the granting of degrees was adopted in this country on the establishment of the London University; with this peculiarity, that while in Germany the different faculties of the universities retain the privilege of conferring degrees, which, however, are of little value, unless confirmed by the authority of the boards alluded to, in the London University this right is vested in the board to the entire exclusion of the professors. Whether this system will work well remains yet to be seen; but, to use the words of Mr. M'Culloch, "if we mistake not, its formation will mark the commencement of a new era in the history of education."

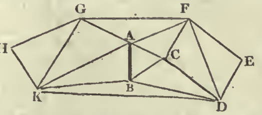
Degree. In Algebra, a term applied to equations to denote the highest power of the unknown quantity. Thus, if the index of the highest power of the unknown quantity is 4, the equation is said to be of the fourth degree.

Degree, in Geometry and Trigonometry, is the 360th part of a circumference, or of four right angles. Every circle, whether great or small, is considered as divided into 360 parts or *degrees*, each degree being subdivided into 60 minutes, and each minute into 60 seconds. This division of the circle has been employed since the most remote ages. It is not certainly known what gave occasion to the adoption of the arbitrary number 360; but it most probably had reference to the space described by the sun in one day in performing his annual revolution in the ecliptic, the number 360 being taken instead of 365, as being more convenient for arithmetical operations on account of its containing a great number of divisions. The Chinese divide the circle into 365¼ equal parts; so that the sun describes daily an arc of one Chinese degree. An attempt was made by the French philosophers, at the period of the Revolution, to introduce into works of science a division of the circle better adapted to our decimal arithmetic (the quadrant or right angle being divided into 100 degrees, the degree into 100 minutes, and so on); but though the system was adopted by some writers of the first order of merit (for example, Laplace in the *Mécanique Céleste*), and extensive tables were computed for the purposes of astronomical calculation, it never came into general use, and now appears to be entirely abandoned. It may be remarked, that a division of this sort was recommended long ago by some of the most eminent mathematicians, Stevinus, Wallis, Briggs, Gellibrand, Newton, and others.

Degree. In Grammar. *See* Comparison.

DEGRE'E OF LATITUDE, on the surface of the earth, is the distance an observer must advance along the meridian, to the north or south, in order to produce a variation of one degree in the altitude of the pole. Ever since it was discovered that the earth is round, the exact measurement of a degree of the terrestrial meridian has been a problem of extraordinary interest, inasmuch as it leads directly to a knowledge of the earth's dimensions. In modern times the problem has acquired a still greater importance, in consequence of the discovery of the earth's ellipticity; for it is by the comparison of the lengths of meridional degrees at different latitudes that we are enabled to ascertain accurately the true figure of the earth, which enters as an element into many of the most interesting inquiries of physical astronomy.

When we consider the great irregularities of the actual surface of the earth, and that the length of a degree depends on the radius of the circle on which it is measured, it will readily appear that terrestrial degrees at different places, if measured on the external surface, must be exceedingly unequal. In order to obviate the effects of superficial irregularities, and to reduce all the degrees to the same radius, the surface of the sea is supposed to be continued all round under the continents, and it is to this surface or level that all the measurements must be referred. This being understood, the general principle on which the measurement of degrees of the terrestrial meridian must be accomplished are readily perceived. Two stations being assumed on the same, or nearly the same meridian, the distance between them must be found with great exactness in feet, yards, or some known linear measure. Having ascertained the itinerary distance, the latitude of each of the stations must be determined; the difference of the two latitudes is the length of the celestial arc intercepted between the two stations; and by comparing this with the terrestrial measure, the number of yards or feet corresponding to a degree becomes known. It is evident that, in order to obtain a result of any value, all these operations must be executed with the greatest care and precision. An error of a single second in the celestial arc corresponds to about 100 feet on the ground, and a long series of astronomical observations must be made to obtain the latitude of any place true to a second. On this account it is necessary to measure an arc of considerable length, two or three degrees at least; because the error in the determination of the latitudes is the same, whether the arc be long or short, and in the case of a long arc its influence becomes less sensible. But the exact measurement of a line extending two or three degrees on the surface of the earth, by the direct application of rods or chains, is perhaps altogether impracticable, on account of the irregularities of the ground and many other circumstances which render an operation of this sort, when carried on even for a few miles, an affair of great difficulty. Hence it becomes necessary to have recourse to other methods. A level piece of ground is selected near the meridional arc proposed to be measured. On this a straight line A B is traced in any direction, and its length accurately found by the application of rods of metal, or sometimes of wood or of glass. The ground adjoining the arc to be measured is then formed into triangles by means of signals, C,D,E,F,K, erected at convenient distances, or on remarkable points of the country; and the angles which the signals make with each other determined by a theodolite or other appropriate instrument. The sides A C and B C are then deduced from the measured base A B, and thence successively the sides of the other triangles; and in this manner the whole distance between the stations which form the terminal points of the arc is determined by a series of trigonometrical calculations. The reductions for differences in the levels of the signals must next be applied, and also for their altitude above the level of the sea; and it is obvious that these reductions cannot be made without having at least an approximate knowledge of the dimensions of the earth, and without making some hypothesis respecting its figure, though the dimensions and figure of the earth are elements that can only be deduced from the measurement and comparison of degrees.



From this general description it will be readily inferred that the measurement of terrestrial degrees depends on astronomical operations of very great nicety, and that the

attempts made in ancient times could lead only to rude approximations with respect to the dimensions of the earth, supposing its figure to be spherical. Eratosthenes, who lived in the 3d century before Christ, is the first with the detail of whose operations we are acquainted who undertook to determine the length of a meridional arc on correct principles. Having observed the difference of the sun's altitude at the summer solstice at Alexandria and Syene in Upper Egypt, and having found, by means with which we are unacquainted, the itinerary distance between the two places, he inferred the circumference of the earth to be 250,000 stadia, and consequently the length of a degree 694⅓ stadia. Posidonius, some time after, measured in a similar manner the arc between Alexandria and Rhodes, and inferred the length of the degree to be 666⅔ stadia. Ptolemy, in his Geography, assigns 500 stadia as the length of a degree of the meridian; but as we are unacquainted with the precise value of the stadium, we cannot form any correct idea of the approximation attained in these ancient measures. In the 9th century, the Arabian caliph Almamoun ordered a degree to be measured on the plains of Mesopotamia. His mathematicians arrived at the exact value given by Ptolemy; a circumstance which, as it could scarcely have happened if they had operated independently, has led to the suspicion that they merely adopted the conclusion of the Greek astronomers. In modern times the measurement of terrestrial degrees has been justly regarded as of the greatest scientific importance. About the middle of the 16th century, Fernel made a rough measurement of the distance between Paris and Amiens by counting the revolutions made by his coach wheel, and concluded the length of the meridional degree to be 364,960 English feet. Norwood, in 1635, measured the distance between London and York, and found the length of the degree to be 367,176 feet. But the first who employed the method of triangulation for obtaining the length of a terrestrial arc was Snell, a native of Holland. The application of the telescope to instruments for measuring angles, by Picard, was an invention which gave a far greater accuracy and certainty to operations of this kind than could before be attained; and the discovery by Richer of the flattened form of the earth at the poles, and the consequent inequality of the meridional degrees, invested the subject with a new and unexpected interest. In the year 1735, the Academy of Sciences of Paris, to decide the important question of the spheroidal form of the earth, resolved that two arcs of meridian, the one at the equator and the other as near the pole as possible, should be measured with all the accuracy which the improved state of astronomy admitted of. Accordingly, Bouguer, Godin, and Condamine were despatched to Peru; Maupertuis, Clairaut, Lemonnier, and some other associates, to Lapland,— for the execution of this purpose. The latter party accomplished their mission, and returned to Paris within 16 months; Bouguer and his companions had to contend with great difficulties and hardships, and were detained not less than ten years. The result was, that the length of the degree of the meridian at the equator, reduced to the level of the sea, was found to be 56,753 toises, or 362,912 English feet; and in Lapland, under the parallel of 65½°, to be 57,437 toises, or 36,729 feet, exceeding the former by 684 toises.

Since these memorable expeditions several arcs of meridian have been measured in different countries, and all the results concur in proving that the degrees increase in length as we proceed from the equator to the pole, agreeably to the theory of hydrostatic equilibrium, which requires an accumulation of matter in the equatorial regions of the earth, in order to counterbalance, by its attraction, the effect of the centrifugal force of rotation. Lacaille, in 1751, measured a degree at the Cape of Good Hope; and the result is interesting on account of the locality, as no other operation of the kind has yet been undertaken in the southern hemisphere. In the same year an arc was measured in the Roman states by Maire and Boscovich; another by Liesganig in Hungary in 1762; one in North America by Mason and Dixon in 1764; and one by Beccaria in Piedmont in 1777; but the results cannot be regarded as entitled to much confidence in comparison of those obtained from the more extensive and accurate operations that have been since executed in France and England, and also in India. The French philosophers, in 1792, having chosen for the unit of their new system of weights and measures a fractional part of the terrestrial meridian, it was resolved to measure the arc extending through the whole of France from Dunkirk to Barcelona. This splendid undertaking was confided to two astronomers of the highest eminence, Mechain and Delambre, by whose spirited exertions it was carried through in the face of obstacles of the most formidable kind, arising from the political state of the country at that time. Every precaution that profound theory or eminent practical skill could suggest was adopted to secure the accuracy of the results. In 1806 the triangulation was extended from Barcelona through Spain to the coasts of the Mediterranean; and subsequently, after the death of Mechain, who fell a victim to his exertions, by Biot and Arago to the Balearic Isles. The whole, thus extended from Dunkirk on the north to Formentera on the south, comprehends 12° 22′. The English arc, connected with the trigonometrical survey of the kingdom, which has been carried on since 1790 under the direction of the Board of Ordnance, reaches from Dunnose in the Isle of Wight to Burleigh Moor in Yorkshire; nearly 4 degrees. Though no doubt is entertained that the result of this measurement is of a high degree of accuracy, it must be confessed that our confidence arises rather from the great excellence of the instruments employed than the science or skill of those to whom the operations were entrusted. It is deserving of remark that both the French and English arcs present this anomaly, that when portions of them taken at particular places are considered separately, the length of the degrees appears to increase on going southward. Two arcs of meridian have been measured in India. The first extends only a degree and a half; but the second is the longest which has been measured in any country, and includes about 16 degrees. It was begun, and about 10° executed, by Colonel Lambton; and the remainder was conducted by Captain Everest. The details of Colonel Lambton's operations are given in the *Asiatic Researches* (vols. viii. to xiii.); those of Captain Everest, in his *Account of the Measurement of an Arc of the Meridian between the Parallels of* 18° 3′ *and* 24° 7′. London, 1830.

Some portions of meridional arcs have more recently been measured in Europe; but as our limits will not permit us to enter into further details, we shall content ourselves with giving the following table of the results of those which appear to be deserving of confidence:—

No.	Meridional Arcs.	Amplitude or length of Arc.	Latitude of middle point.	Length of Degree in English feet.
1.	Arc measured by Bouguer, recomputed by Delambre - - -	3° 7′ 3′	1° 31′ 0″ S.	362,809
2.	First Arc measured in India by Col. Lambton, from Trivandeporum to Paudree - -	1 34 56	12 32 21 N.	362,988
3.	Second Indian Arc by Col. Lambton and Captain Everest, from Punnae to Kulliampoor -	15 57 59	16 8 22	363,040
4.	French Arc from Dunkirk to Formentera by Mechain and Delambre -	12 22 12	44 51 ·	364,644
5.	English Arc from Dunnose to Burleigh Moor -	3 57 13	52 35 45	365,032
6.	Arc measured in Hanover by Gauss, from Gottingen to Altona - -	2 0 57	52 32 17	365,301
7.	Arc measured in Lithuania by Struve, from Jacobstadt to Hockland	3 35 5	58 17 37	365,377
8.	Arc measured in Sweden by Svanberg, from Maltorn to Pahtawara -	1 37 20	66 20 11	365,697

In the above table the numbers are exhibited as if the whole arcs had been measured at once, and the latitudes only observed at each extremity; but in fact, in the three long arcs, latitudes were observed at several intermediate stations, and consequently so many more independent measures obtained. Thus the second Indian arc consisted of five partial arcs, the French of six, the English of three, and Struve's of two; so that there are in the whole *twenty* independent determinations of the meridional degree. Combining the results of these twenty measurements by methods well known to mathematicians so as to deduce the most probable mean values, the dimensions and ellipticity of the earth are found to be as follows:—

	English feet.		Miles.
Equatorial diameter - -	41,843,330	=	7924·87
Polar diameter - -	41,704,788	=	7898·63
Difference of diameters - -	138,542	=	26·24
Ellipticity, or difference of diameters divided by greater - -	$\frac{1}{302{\cdot}026}$		

Assuming these as the true elements of the earth's magnitude and figure, the following table is calculated, showing the length of a degree of the meridian at every 10th degree of latitude. The formula from which the calculation is made is the following:— Let a be the equatorial semidiameter of the earth, e the ellipticity, l the latitude of the place, and d the length of a degree at the latitude l; then $d = a\,(1 - e + 3\,e \sin^2 l)\ 3600 \sin.\ 1''$.

Latitude.	Length of Degree in English feet.	Latitude.	Length of Degree in English feet.
0	362,734	50	364,862
10	362,843	60	365,454
20	363,158	70	365,937
30	363,641	80	366,252
40	361,233	90	366,361

DEGREE OF LONGITUDE, on the earth, is a degree of the equator, or of any of its parallel circles. If the earth is a regular spheroid of revolution, the circles parallel to the equator, and consequently the degrees of those circles, must diminish regularly as their distance from the equator increases, according to a law derived from the nature of the ellipse. Hence, if we know the measured lengths of a degree of two or more small circles in different latitudes, we are in possession of data sufficient to determine the diameters and ellipticity of the earth. The measurement of degrees of longitude, therefore, in reference to the determination of the earth's figure, is of equal importance with the measurement of degrees of the meridian, and has accordingly been executed in various instances. The geodetical operations required in the one case are the same as in the other; but on account of the great difficulty of determining the astronomical longitudes with the necessary accuracy, the results have never been regarded as equally satisfactory. Supposing the equatorial diameter of the earth, as indicated by the meridional degrees, to be 41,843,330 English feet, and the ellipticity $= \frac{1}{302{\cdot}026}$, the following table shows the length of a degree of longitude at every tenth degree of latitude.

Latitude.	Degree of Longitude in English feet.	Latitude.	Degree of Longitude in English feet.
0	365,152	50	235,171
10	359,640	60	183,029
20	343,263	70	125,254
30	316,493	80	63,612
40	280,106	90	0

DEGRE'ES. In Music, the small intervals of which the concords or harmonical intervals are composed.

DEHI'SCENT. (Lat. dehisco, *I gape.*) A term applied to those fruits which separate regularly round their axes, either wholly or partially, into several pieces.

DEIFICATION. *See* APOTHEOSIS.

DEI GRATIA (*by the grace of God*). A Latin formula, usually inserted in the ceremonial description of the title of a sovereign. It was used originally by the clergy.

DEILE'PHILA. (Gr. δειλη, *evening*, and φιλεω, *I love.*) A subgenus of hawk-moths (*Sphingidæ*) belonging to the crepuscular or evening tribe of Lepidopterous insects. They are characterized by wings entire and acute; antlia rather elongated; antennæ short, and clubbed in the male. One species, *Deil. celerio*, feeds upon the vine.

DEINOTHE'RIUM. (Gr. δεινος, *terrible*, θηριον, *wild beast.*) The name of a fossil genus of gigantic Pachyderms, chiefly remarkable on account of its enormous tusks, which projected downwards from the lower jaw instead of the upper, as in the elephant and walrus.

DE'ISM, or THEISM. (Lat. Deus; Gr. Θεος, *God.*) Belief in the existence and attributes of God, coupled with disbelief in any express revelation of his will. There exist various shades of opinion among Deists, which the reader will find pointed out in Clarke's learned work on the *Attributes*; but general usage has assigned this word a meaning synonymous with *sceptic* or *freethinker:* hence it is regarded as a term of reproach. In its original acceptation, *theist* was directly opposed in meaning to *atheist;* but these terms are now frequently, though very incorrectly, employed without distinction to designate an *unbeliever in Christianity.*

DEJEUNER. (Fr. *breakfast.*) A term wholly naturalized in almost all the languages of modern Europe, not excepting the English, signifying the morning meal. The materials of which it is composed vary of course with the climate and usages of different countries; but it is worthy of remark that in France itself this term is rapidly losing, if indeed it has not already lost, its original acceptation, being used, particularly by the fashionable world, as synonymous with the English *luncheon.*

DEL CREDERE COMMISSION. In Mercantile Law, a term derived from the Italian (credere, *to trust*), which denotes a commission granted by a merchant to a factor to dispose of goods; the factor, for the consideration of an additional per-centage, agreeing to guarantee the solvency of the purchaser. *See* FACTOR.

DE'LEGATES, COURT OF. Formerly the highest ecclesiastical court of appeal in England: in ordinary cases composed of three common law judges and three civilians; in special cases a fuller commission is sometimes issued. In case of a division of opinion, or where no common law judge is in the majority, a commission of adjuncts was issued. Appeal lay to it from the archiepiscopal courts. Its powers are transferred by 2 & 3 W. 4. c. 92. to the privy council.

DELEGA'TION. In the Civil Law, the act by which a debtor transfers to another person the duty to pay, or a creditor makes over to a third party the right to receive payment.

DELFT WARE. A coarse species of porcelain, originally manufactured at Delft in Holland, whence its name.

DE'LIAN PROBLEM. *See* DUPLICATION OF THE CUBE.

DE'LICACY. (Lat. deliciæ.) In the Fine Arts, minute accuracy as opposed to strength or force: slenderness of proportion, great finish, and softness are its characteristics.

DELIQUE'SCENCE. (Lat. deliquesco, *to melt down.*) When certain saline substances are exposed to air, they absorb so large a quantity of moisture as to run down into a liquid state, or *deliquesce.*

DELI'RIUM TRE'MENS. A disease of the brain, resulting from the excessive and protracted use of spirituous liquors; it is therefore almost peculiar to drunkards. It begins with excessive irritability, loss of sleep, frightful dreams and visions, and a multiplicity of the ordinary delusions of insane persons, ending in furious madness. The hands are usually, but not always, tremulous. By careful treatment, and more especially by the judicious use of opium, patients have recovered from this disease; but, for obvious reasons, it is difficult to manage, and subject to relapses. Bleeding should in almost all cases be, if possible, avoided.

DE'LITE'SCENCE. (Lat. delitescere, *to lie hid.*) In Surgery, when a tumour very suddenly and unexpectedly subsides, it is said to terminate in *delitescence.*

DE'LPHI, ORACLE OF; so called from Delphi, the capital of Phocis, the most famous of all the oracles of antiquity, sacred to Apollo. The origin of the oracle at Delphi is wrapt in obscurity. By some authors it is ascribed to chance; but many incline to believe that it owed its origin to certain exhalations, which, issuing from a cavern on which it was situated, threw all who approached it into convulsions, and during their continuance communicated the power of predicting the future. Be this as it may, these exhalations were soon invested with a sacred character; and as their reputation extended, the town of Delphi insensibly arose around the cavity from which they issued. The responses were delivered by a priestess, called Pythia, who sat upon a tripod placed over the mouth of the cavern; and after having inhaled the vapour, by which she was thrown into violent convulsions, gave utterance to the wished-for predictions, either in verse or prose, which were then interpreted by the priests. Originally the consultation of the oracle was a matter of great simplicity; but in process of time, when the accuracy of the predictions became known, a series of temples, each more magnificent than its predecessor, was erected on the spot. Immense multitudes of priests and domestics were connected with the oracle; and to such a height of celebrity did it attain, that it wholly eclipsed all the other oracles of Greece.

The position of the oracle was the most favourable that could well be imagined. Delphi formed at once the seat of the Amphictyonic Council and the centre of Greece, and, as was universally believed, of the earth. Hence, in every case of emergency, if a new form of government was to be instituted, war to be proclaimed, peace concluded, or laws enacted, it came to be consulted, not only by the Greeks, but even by the neighbouring nations; and thus the temple was enriched by an incredible number of the most valuable presents and the most splendid monuments, and the town of Delphi rose to be one of the most wealthy and important of the cities of Greece.

As it was well known that the riches of all Greece were concentrated in the temple at Delphi, this sacred repository became frequently an object of plunder. But in spite of all the rapacity to which it was exposed, the oracle continued to utter its responses long after the seat of empire had been transferred from Greece to Rome; and it was only when Constantine the Great removed the sacred tripods to adorn the hippodrome of his new city, that the responses of the oracle ceased to be delivered. For a view of the characteristics of oracles in general, and the influence which they exercised over the nations of antiquity, see the article ORACLE.

DE'LPHIN. In Literary History, a name given to the edition of the Latin classics, prepared and commented upon by thirty-nine of the most famous scholars of the day, at the suggestion of Louis XIV., for the benefit of the young prince (in usum Delphini) under the superintendence of Montausier his governor, and his preceptors Bossuet and Huet.

DELPHI'NIA. A vegetable alkaline base, obtained from the seeds of the *Delphinium staphisagria*, or stavesacre.

DELPHI'NUS. (Lat. *a dolphin.*) The *Dolphin*, one of the ancient constellations of the northern hemisphere.

DELPHINUS. This term is restricted in modern Zoology to those species of Cetacea which have teeth in both jaws, all simple, and almost all conical. They are the most carnivorous in proportion to their size. The Linnæan genus *Delphinus* is now subdivided into *Hyperoodon*, of which the great bottle-nose dolphin is the type; *Delphinapterus*, represented by the beluga; *Phocæna*, represented by the common porpesse; and *Delphinus* proper.

DE'LTA. The Greek letter Δ; and, in antiquity, the lower portion of Egypt, comprised between the E. and W. branches of the Nile and the sea, was from its resemblance to the above letter called the Delta. And hence if any large river, before it enters the sea, diverges and forms two sides of a triangle, the sea being the base, the strand or alluvial land included by the three lines is called a *delta;* as the delta of the Rhone, the Danube, Ganges, &c.

DELTO'ID. Of the shape of the Greek letter delta, Δ. The term is used in anatomy and botany.

DE'LUGE. (Lat. diluvium.) In the 1656th year after the creation (according to ordinary chronology), in the 600th year of the life of Noah, and on the 17th day of the second month (November, according to some commentators), the waters began to rise upon the earth. They appear to be represented as swelling upwards by some upheaving force (the fountains of the great deep were broken up), and descending also in continual rain for forty days and nights. All the mountains "that were under the whole heaven" were covered; "all flesh perished that moved on the earth," with the exception of Noah and his family, and the animals which entered with him into the Ark. The waters remained 150 days; and then "returned from off the earth continually:" and the Ark rested on Ararat on the seventeenth day of the seventh month; and on the first day of the first month of the following year "the face of the ground was dry," but not completely drained of the water for nearly two months longer. Such is a very concise abridgment of the account of this great catastrophe contained in the 7th and 8th chapters of Genesis. Two subjects connected with it require a brief discussion:—the parallel traditions of ancient mythology; and the confirmation which the Mosaic account has been supposed by some to receive from the discoveries of modern geological science, which others have represented as directly opposed to it.

As to the first, the belief in the destruction of mankind by a deluge in the earliest times, and of the escape of one individual and family under circumstances resembling those recorded in sacred history respecting Noah, is a remarkable feature in the traditions of a great variety of nations. The Fo-ki of the Chinese, the Satyavrata of the Indians, Xisuthrus or Seisithrus among the Assyrians, Deucalion and Ogyges among the Greeks,—all present striking features of analogy to the patriarch of scripture: even the Mexicans had their traditional deluge. These fragments of early belief are collected very copiously in the third volume of *Bryant's Ancient Mythology*. (See also *Russell's Connexion of Sacred and Profane History*, vol. ii.) It is undoubtedly true that some of these deluges may have been local inundations only; as, for example, the natural features of the Thessalian plain seem to account conclusively for the tale of Deucalion. Still the universality of these traditions, and their general agreement as to circumstances, seem to point to some common source of information.

With regard to geological theories of the deluge, it is perhaps the safest and wisest course to acquiesce in the general principle, that as scripture was given for a very different purpose than that of conveying physical knowledge, so the endeavour to torture its brief language into exact accordance with our discoveries, real or imaginary, in that branch of inquiry, is both vain and unreasonable. But since much controversy has been expended on the subject, it may be worth while to observe, that in the instance of the deluge, the chief difficulties have arisen not from any endeavour of infidel writers to confute scripture by the aid of geology, but through the over eagerness of the advocates of religion to seize on each hasty generalization made in the progress of an advancing science, in order to press it into the service of their own opinions. Thus the cause of revelation has been defended by physical arguments where no defence was called for; and these arguments have been necessarily abandoned afterwards by those who advanced them. We need not here speak of the notions which have been propounded by speculative geologists respecting the proximate causes of the deluge; such as Burnet (*Telluris Theoria Sacra*), Newton, &c.; and Dr. Geddes, whose ingenious theory is, that it was produced by a sudden increase of the central heat expanding the volumes of water supposed to be contained in cavities of the globe, breaking up its surface from within, and then submerging it under an inundation of *hot* water. More general interest has been excited by the imaginary proofs which from time to time geology has been supposed to furnish of the *fact* of a universal deluge. Thus the discovery of fossil shells in inland strata, and near the summits of the highest mountains, was at one time offered as conclusive evidence; and some infidel writers were reduced to the absurd shift of representing them as *lusus naturæ*, or accounting, like Voltaire, for those found on the Alps by supposing them to have been thrown away by pilgrims on their journey! But when, in the course of discovery, it was known that these fossil relics are to be found scattered through an infinite variety of solid strata formed apparently by partial deposition, one reposing beneath another, so as to form the whole superficial crust of the globe, the impossibility of considering them as the results of any great convulsion became evident, and the argument founded on them fell to the ground. A similar instance of over hasty conclusion has been exhibited in more recent times. Some geologists imagined themselves to have discovered proofs of a general convulsion, attended by a rapid passage of water over the surface of the whole earth, at a period subsequent to the deposition of the last tertiary strata. This notion is to a certain extent countenanced by Cuvier (*Theory of the Earth*, Dr. Jameson's translation, pp. 11. 13. &c.), and by Dr. Buckland (*Reliquiæ Diluvianæ*, 1823.); and it is unfortunate that Dr. Sumner (*Records of the Creation*) should have adopted it as the foundation of an argument in favour of revelation. For more recent investigations have shown that it is impossible to distinguish these supposed traces from those of local disturbance.

On the whole, the question may perhaps be summed up thus: many writers (Cramer, Von Hoff, &c.) have contended that the scriptural deluge was local only, extending over the then inhabited portion of the earth; but if it is to be regarded as universal, and the expressions of the Bible taken in their literal sense, geology (in its present very imperfect state) affords us no insight into the possible *causes* of such a convulsion. But on the supposition of its having been produced by a sudden miraculous interference with the order of nature, no such information was to be expected from science. Neither does geology afford any distinct *evidence* of a universal deluge; but, looking at the manner in which that deluge is recorded to have taken place, and the short period of its duration, it is difficult to see how any permanent results which it may have produced *could* be distinguished from those of the innumerable local inundations of which the surface of the earth furnishes such manifest testimony. The points of contact between natural science and revelation are in reality few or none; it is the jealousy of believers on the one hand, and the cavils of scepticism on the other, which have given rise to the very unmeaning controversies which exist upon the subject.

DE'MAGOGUE. (Gr. δημος, *people*, and αγωγος, *leader*.) One who directs or leads the people in political matters. In its original acceptation it was considered as a most honourable designation, having been applied to Solon, Demosthenes, and in fact to many of the most illustrious characters of antiquity; but it is now almost invariably used in a bad sense. The oldest and most satirical of all portraits of the demagogue is traced by Aristophanes in his play of the *Knights*, in the character of Cleon.

DEMA'ND. In Political Economy. *See* SUPPLY AND DEMAND.

DEMARCA'TION. (Fr.) A term used to designate the line or boundary by which one object is separated from another. The word was first introduced in 1493, when Pope Alexander VI., in order to put an end to the disputes which prevailed between the crowns of Spain and Portugal relative to their Indian discoveries and conquests by virtue of his pontifical authority drew through the ocean an imaginary line, by which the dominions of both parties were defined; and thus originated the expression *line of demarcation*. It is only in this phrase that the word is employed to this day in all the languages of Europe.

DEMES'NE. (Lat. terra dominicalis.) In Law, originally that portion of the lands belonging to a lord which was held in his own occupation. Hence it is sometimes used to distinguish those parts of a manor which the lord has in his own hands, or those of lessees at rack-rent, from those which are in the hands of freeholders and copyholders. *See* ANCIENT DEMESNE.

DEME'TER. (Doric Gr. δα, *the earth*, and μητηρ, *a mother*.) The Greek appellation for Ceres (quod vide).

DE'MI. (Fr.) A word signifying *half*, frequently used in the composition of English words, being equivalent to the Latin *semi*.

DE'MIDITO'NE. (Gr. διτονος.) In Music, a minor third. *See* THIRD

DE'MIGODS. A general appellation of the inferior divinities of Greece and Rome, more particularly of such of the mixed offspring of divinities and mortals as were afterwards deified. Of these the number was almost incredible; and though their worship was not cultivated with such veneration or solemnity as that of the superior gods, it prevailed to a greater or less extent in every quarter of the ancient world, and formed a large part of the heathen mythology.

DE'MILUNE, in Fortification, is a work placed before the curtain.

DE'MIQUAVER. In Music, a note equal in duration to half a quaver.

DE'MITINT. In Painting, a tint representing the mean or medium between light and shade; by some called a *half tint*.

DEMIU'RGUS, *Demiurge*. (Gr. δημιουργος, from δημος, *people*, εργον, *work*.) In the original sense of the word, as used by classical authors, an artificer employed

in ordinary handicraft. In the language of Platonist writers, it denotes an exalted and mysterious agent, by whose means God is supposed to have created the universe. Hence the Demiurgus, or Logos, as the same imaginary agent is termed in the *Timæus* of Plato, is identified by the Platonizing Christians with the second person in the Trinity.

DEMO'CRACY. (Gr. δημος, *people*, and κρατεω, *I govern.*) A government is usually termed a democracy in which the whole of the people, or a large proportion of it, exercises sovereignty either directly or by representatives. According to some political writers, the term is strictly appropriate only where "a majority of the adult males" share in the government. In Aristotle's view of governments, democracy is a perversion of the imaginary system, which he terms Politeia, or commonwealth par excellence; in which the majority are supposed to govern for the good of the whole, while in democracy they govern for their own. *See* REPUBLIC.

DE'MOGO'RGON. (Gr. δαιμων, *a demon*, and γοργος, *terrible.*) In Mythology, a mysterious divinity of antiquity, of whose origin, attributes, and history no satisfactory account can be given, in consequence of the obscurity in which they are enveloped. By some writers he is regarded as the author of creation; others consider him to have been a famous magician, to whose spell all the inhabitants of Hades were subjected; but all concur in viewing him as an object rather of terror than of worship: hence in the *Paradise Lost* (Book 2.), Milton speaks of

> ——— the dreaded name
> Of Demogorgon.

For further information the reader is referred to one of the most learned works of any age or country, the *Dictionnaire de Trevoux*.

DE'MOISELLE. In Zoology. *See* GRINDAE.

DE'MON. (Gr. δαιμων, *a spirit.*) The existence of invisible beings of superior powers and intelligence to mankind, though inferior to the Deity, has been an article of belief among all heathen nations. They have varied, however, in the dispositions they have assigned to them. The Greeks, from whom we derive the term in Scriptural language, applied it originally to the deified spirits of departed heroes, whom they supposed to have some influence in promoting the good of mankind, and considered therefore as objects of adoration. The manner, however, in which demons are represented in Scripture as evil spirits inflicting injury on men at the suggestion of the Father of Evil, is conformable to the oriental notion upon such points; except, indeed, that in the Scriptures the general supremacy of God, who suffers evil to exist, is maintained, in opposition to the eastern dogma of the eternal and equal conflict of the good and the evil principles. The early fathers indulged in much speculation upon these subjects; but in modern times the literal interpretation of the agency of demons as referred to in Scripture has been frequently called in question. The demons, like the fairies and goblins of other mythologies, are represented with various characters of beneficence, malice, and wanton mischief. They were sometimes distinguished by the names Cacodemon and Agathodemon (from κακος, *bad*, and αγαθος, *good*), according as their influence was evil or beneficent.

DEMO'NIACS. Persons possessed by or under the influence of demons or devils, of whom mention is made in some passages in the New Testament. Some divines have supposed that such influence was permitted to the powers of evil at one particular time for the greater manifestation of our Lord's authority in rebuking them: but it is certain that the idea of demoniacal possession was very ancient among the oriental nations; and those to whom it seems incredible that it should have been grounded on fact, must be content with interpreting such passages of Scripture as a concession to the opinions and feelings of the Jewish people.

DEMONO'LOGY. (Gr. δαιμων, *deity* or *dæmon*, and λογος, *discourse.*) The belief in an intermediate race of beings, between deity and humanity, has been a prevalent feature in almost every popular creed; and all tradition or speculation respecting it may be said to fall under the general term of Demonology. Among the early oriental nations, especially the Persians and Egyptians, the science of astronomy appears to have been essentially connected with this branch of superstition; the heavenly bodies were honoured as dæmons or celestial intelligences. This ancient belief appears to have had much influence on the Jewish rabbinical writers; and out of it, connected with what is revealed to us in the Old Testament of the existence and attributes of angels, they framed their peculiar mythology.

The Greek word δαιμων, *dæmon*, is said to be derived from δαημων, *knowing* or *intelligent*. In the earliest monuments of the language, its signification is vague and uncertain. In Homer it generally signifies a deity: δαιμονιον is anything godlike, wonderful, which may have been communicated or inspired by a deity; but, in the *Odyssey*, some traces are to be found of the meaning "fortunate" or "unfortunate" attached to the word. In Hesiod, however, we have an express mythological account of the dæmons,—as spirits, in a state between mortality and divinity, peaceful and favourable to man: he describes them as of different orders. The mortals who lived in the golden age have become dæmons of the first rank; those of the silver age have inferior honours, and are mortal, although their life is prolonged to a length of many hundreds of human generations. The heroes form a still inferior class of intermediate spirits. In popular language, when hero-worship became widely spread in Greece, the word hero and dæmon were used without much distinction; but the more recondite difference appears to have been this,—the hero was the departed worthy himself, such as he had once lived on earth; the dæmon was his immaterial part, converted into a sort of abstract principle,—a spiritual agent of good or evil, favourable or unfriendly to mankind. It is in this sense also that the inferior deities themselves are designated as dæmons. Thales is said to have defined more accurately the difference between gods, heroes as the souls of deceased mortals, and dæmons properly so called; and in Plato's theology the dæmons occupy an important place—as intermediate spirits, closely watching over, directing, and recording the actions of mortals. By later writers they were divided into many classes: some ministers of punishment and revenge, some freeing from evils already befallen (λυσιοι), some warding off their approach (αλεξικακοι), &c. It was in Egypt and Syria, under the Ptolemies and Seleucidæ, that the Grecian philosophy and mythology came in contact with those of the Rabbis; and from that union a new mixed system of dæmonology took its origin. Hence, in the Greek of the New Testament, the word δαιμονιον is taken, without addition or qualification, as an evil spirit, and rendered by our translators "devil."

Analogous to the dæmons of the Greeks were the genii of the Romans; but there were peculiar and characteristic features about the belief in the latter which show it to be of a different origin, probably derived from the Etruscans, who, as some antiquarians believe, drew their mythology from the ancient source of Samothrace. The genii of the Romans were an innumerable host of spirits: every man, house, or city had an attendant genius. The genius of every mortal is mortal as himself; accompanies him into life, and conducts him in all its vicissitudes. In this sense, the genius was a favourable companion: to enjoy the good things of life is represented as "indulging" or gratifying the genius; abstaining from them, as "defrauding" him. Wine and flowers are appropriate offerings to him. But he is also "vultu mutabilis, albus et ater:" he is the companion of the mischances as well as the pleasures of life; unless, as the difficulty appears sometimes to have been solved, the individual had his *pair* of genii, good and bad. And this latter should appear to have been the popular belief among the Etruscans, as far as we can collect it, in a subject where all is vague and indistinct; and it is impossible accurately to separate the abstract creations of philosophers and poets from the substantive objects of general belief. The Etruscans represented the evil genius as a dark and frightful figure, attending a mortal on one side, who is protected or followed on the other by a child or youth—the usual emblem of the good genius. The genius is often represented on vases and in ancient paintings as a winged figure; and a genius holding a torch downwards is the emblem of death.

The dæmons of the middle ages were simply fallen angels or devils, according to the sense of the word in the New Testament; and hence demonology, in the language of modern writers, generally signifies the history of the supposed nature and properties of such evil spirits, and of the modern superstition respecting compacts between them and mankind. *See* MAGIC, WITCHCRAFT.

DEMONSTRA'TION (Lat. demonstro, *I show*), was used by the old writers to signify "any manner of showing either the connection of a conclusion with its premises, or that of a phenomenon with the asserted cause; but it now means, in philosophical language, only that process by which a result is shown to be a necessary consequence of the premises from which it is asserted to follow, on the supposition that those premises are admitted, either as matter of fact, or of intuitive evidence, or of previous demonstration." Demonstration is also used in ordinary language as synonymous with *proof:* thus it is often said that "evidence amounts to demonstration."

DEMONSTRATIONS, in a Military sense, are manœuvres practised for the purpose of misleading the enemy.

DE'MOS. (Gr. δημος.) In Ancient History, a borough or ward; an Attic word, denoting one of the districts into which Attica was divided, and which in early times were bound together by the ties of common blood, but were not united closely into one nation till the time of Theseus, who fixed on Athens as the nucleus of the state.

DEMU'RRAGE. In Mercantile Law, the delay which a merchant makes in loading or unloading a ship, beyond the time specified in his charter-party, or other agreement with the owners; in which it is usually stipulated that

he shall pay at a certain rate per diem for such extra time, which payment is also termed demurrage.

DEMU'LCENTS. (Lat. demulceo, *I soothe.*) Medicines which sheathe and defend sensible parts from the action of irritating matters; they are chiefly mucilaginous substances, such as gum, starch, &c.

DEMU'RRER. (From the Lat. demoror, *I delay.*) In Law, an issue between plaintiff and defendant on matter of law. It confesses that the facts are true as stated by the opposite party, but denies the legal consequences inferred by the opposite party from these facts. Demurrers are either general or special. (*See* PLEADING.) Demurrers in equity are of the same nature with those at law. Demurrer may be also to an indictment in criminal cases.

DEMY. *See* PAPER.

DENA'RIUS. A Roman silver coin worth ten asses originally, and afterwards considered equal to eighteen asses, when the weight of the latter coin was reduced to one ounce.

Originally the denarius was $\frac{1}{100}$ of a pound of silver, but its weight varied. Its value is considered equal to $7\frac{3}{4}d.$ of English money.

There was also a gold denarius equal in value to wenty-five silver ones.

DENDRO'DOA. (Gr. δενδρον, *a tree*, and ωον, *an egg.*) The name of a subgenus of Ascidians, or fixed tunicated Mollusks, suggested by the ramified form of the ovarium; but this structure is not peculiar to the species included in the genus so designated.

DE'NDROMYS. (Gr. δενδρον, and μυς, *a mouse.*) A South African genus of Rodentia, nearly allied to the true mice, but differing in the habits of the species, which frequent the branches of trees, in which they construct their nest and bring forth their young.

DE'NDROPHIS. (Gr. δενδρον, and οφις, *a serpent.*) A genus of harmless serpents of the great family of Colubers, remarkable for their long and slender body.

DE'NIZEN. (Welsh dinassdyn, *man of the city.*) In Law, an alien born, who has received ex donatione regis letters patent to make him an English subject. He may take lands by purchase and devise; but cannot enjoy offices and trusts, &c., or receive a grant of lands from the crown.

DENOMINA'TOR. A term used in Arithmetic, in speaking of fractions, to denote the number of parts into which the unit or whole is divided. Thus, for example, in the fraction $\frac{7}{12}$ (seven twelfths) of a foot, 12 is the denominator, and indicates that the unit or one foot is divided into 12 equal parts; and 7, the numerator, shows how many of these parts are to be taken. The denominator always indicates unity, for the whole is equal to all its parts. A fraction may always be regarded as a whole number, whose unit is a part of the primitive unit, which part is expressed by the denominator. Thus, in the fraction $\frac{7}{12}$ of a foot, the foot is supposed to be divided into *twelfths* or inches; and $\frac{7}{12}$ expresses the same thing as 7 inches, or the particular unit, an inch, taken seven times.

DENOU'EMENT. (Fr.) A term completely naturalized in England; used to designate the development of the plot or story in a novel or play, and in short in every department of literature.

DE'NSITY (Lat. densus, *thick*), is used in Physics to denote the quantity of matter which a body contains under a given or determinate surface; for example, a cubic foot. The quantity of matter in any body is called its mass, and is measured by the weight of the body, to which it is always proportional. Hence the density of any body is great in proportion as its weight is great and its volume small; or, the density of bodies are directly as their masses, and inversely as their volumes. It follows also from the definition, that if two bodies have the same volume, their densities are directly as their masses or weights; and that if two bodies have the same mass or weight, their densities are respectively in the inverse ratio of their volumes. The density of a body is also proportional to its specific gravity.

DE'NTAL FO'RMULA. (Lat. dens, *a tooth.*) A notation used to signify the number and kind of teeth of a mammiferous animal, and usually forming the main element in its generic character. Thus the cats, or genus *Felis*, are characterized by incis. $\frac{6}{6}$; canin. $\frac{1}{1},\frac{1}{1}$; præmol. $\frac{2}{2},\frac{2}{2}$; mol. $\frac{2}{1},\frac{2}{1} = 30$; which signifies that they have six incisores in both the upper and the lower jaw; one canine tooth on each side of both jaws; two præmolares, or false molares, on each side of each jaw; two true molares on each side of the upper, and two on each side of the lower jaw. The dental formula of man is — incis. $\frac{4}{4}$; canin. $\frac{1}{1}$; præmol. $\frac{2}{2},\frac{2}{2}$; molares, $\frac{3}{3},\frac{3}{3} = 32$.

DENTA'LIUM. A genus of Mollusks inhabiting elongated univalve shells, resembling an elephant's tusk in miniature, whence the name.

DE'NTATE. (Lat. dens.) In Zoology, the margin of a part of an animal is so termed when it is cut into teeth whose sides are equal, or nearly so.

DENTA'TUS. (Lat. dens.) Toothed; applied to the margins of bodies furnished with sharp teeth with concave edges.

DE'NTES (Lat. *the teeth*), properly so called, are parts peculiar to the vertebrate animals, composed of gelatin, hardened principally by the phosphate of lime, and are fixed to the bones of the mouth. They serve to catch, kill, hold, pierce, cut, or crush the objects of food, and are variously shaped accordingly. Substances composed of softer material, generally horn, perform the analogous offices in the invertebrate animals, and are generally called teeth; horny material is substituted for teeth in a few fishes, in chelonians, birds, whales, and the *Ornithorhynchus paradoxus*.

In fishes the teeth may be situated on the intermaxillary, maxillary, mandibular, palatine, vomerine, pterygoid, hyoid, or pharyngeal bones; in a few instances they are implanted in sockets or "alveoli," or they may be fixed to an osseous base which is attached by ligamentous substance to the oral bones; but most commonly they are immediately anchylosed, or joined by a direct continuation of bony substance, to the bones themselves which encompass the mouth.

In reptiles the teeth may be found on the palatine, pterygoid, or vomerine, as well as on the maxillary and intermaxillary bones. They are generally anchylosed, or confluent with the substance of the jaws; but in the plesiosaurs and crocodiles are implanted in sockets.

In mammals the teeth are confined to the maxillary and intermaxillary bones, are always implanted in sockets, and in this class only may be so fixed by more than one fang or root.

Teeth generally consist of three distinct substances; viz. ivory, enamel, and bone, or cæmentum, also called crusta petrosa.

The texture of the ivory is minutely tubular, that of the cæmentum of combined tubules and cells; and the earthy material is arranged principally in these cavities, which have definite arrangement and proportions in each species of animal. The enamel consits of hexagonal filamentary crystals.

In the human subject the teeth are called, according to their figure, "incisors," "canines," "bicuspids," and "molars;" the same terms have been transferred to the teeth of the mammalia generally, except that those which are analogous to the bicuspids in man are called "præmolars," or spurious molars. A tooth is divided into a crown, a neck, and a fang or fangs.

The vascular bodies concerned in their development are called "pulp" and "capsule:" the ivory or body of the tooth is formed by the former, the enamel and cement are due to the latter organ.

In most cases when the pulp has secreted as much ivory as forms the full-sized crown of the tooth, it begins to diminish in size; and as it continues to exercise its function during the progress of its absorption, a gradually decreasing fang is the result: when the absorption of the pulp, instead of being general, proceeds from two or three parts, a corresponding number of fangs are extended from the crown. But sometimes the pulp retains its full size and activity during the lifetime of the animal, in which case the part of the tooth lodged in the socket presents the same size and form as the protruded crown, of which it is a direct continuation. The fore teeth of the rat, beaver, and other rodents are familiar examples of these constantly growing teeth. But this is not the only mode in which excessive wear and tear of the teeth is provided for. In the elephant when one grinder is worn down it is pushed out, and replaced by a second of subsequent formation; these successional teeth, or "dents de remplacement," as they are termed by the French anatomists, are formed in the elephant, each in a cavity at the back part of the jaw, behind the tooth which they are destined to succeed. In other animals again, the teeth which suit the size of the jaws when young are pushed out by others which are proportioned to the size of the full-grown jaws; these, which are termed "permanent teeth," succeed the "deciduous teeth" in the vertical direction, being developed in the substance of the jaws above the deciduous teeth in the upper, and below the deciduous teeth in the lower jaw. As the deciduous series of teeth are generally developed in the mammalia at the period when the young animal is suckling, they are commonly called "milk" teeth; but as in some rodents deciduous teeth are formed and shed before birth, they might be termed "uterine" teeth. Thus teeth may succeed each other in the horizontal or vertical direction. In the human subject all the deciduous teeth are succeeded vertically; but the additional teeth follow each other from behind forwards. In mammalia a tooth has not more than one successor in the vertical direction, but in reptiles and fishes there may be many such.

It is a singular but constant fact, that in mammalia the permanent molar always presents a more simple crown

than the deciduous one which it has replaced; thus, in man, the quadricuspid milk grinders are succeeded by the permanent bicuspides.

DE'NTILS. (Lat. dentes, *teeth.*) In Architecture, small square blocks or projections in the bed mouldings of the cornices in the Ionic, Corinthian, Composite, and occasionally Doric orders. Their breadth should be half their height; and, according to Vitruvius, the intervals between them should be two thirds of their breadth. In the Grecian orders they are not used under modillions.

DE'NTIRO'STRES. (Lat. dens, and rostrum, *a beak.*) The name of a tribe of Insessorial birds, characterized by having a notch and tooth-like process on each side of the margin of the upper mandible. In connection with this organization the Dentirostral birds manifest rapacious habits, and prey on smaller and weaker birds. The butcher-birds belong to this tribe.

DENTI'TION. (Lat. dens.) The cutting of the teeth. At birth the teeth consist of pulpy rudiments buried in the gum; and it is not till the third or fourth month that they begin to assume shape and hardness. At this period children generally become fretful; the saliva flows copiously, and they are fond of biting upon any thing hard and cold; the gums become turgid; there is more or less fever, frequently a cough; and a rash appears, commonly called the *red gum.* These symptoms generally subside in the course of a fortnight or three weeks, and the child remains tolerably free from uneasiness till the seventh or eighth month, when the gums become tender; and often so much so, at some particular spot, that the slightest touch or pressure produces extreme pain: the gums become more red and swollen, but paler at the upper part, which, just before the tooth appears, becomes blistered. During these periods an increased flow of saliva and a lax state of bowels are favourable symptoms; but where the local irritation is considerable, the gums should be freely lanced, and any excessive diarrhœa should be very cautiously checked: small doses of magnesia, or of chalk julap with dill water, and occasionally with a little powdered rhubarb, will generally be sufficient for this purpose. When involuntary motions of the jaws and face, or more general convulsions ensue, and are not relieved by the loss of blood which generally follows proper lancing of the gums, or where there is drowsiness and oppressed respiration, a leech or two to the temples, and a small blister to the back of the neck, or behind the ear, must be promptly resorted to; and any sluggishness of bowels prevented, or even anticipated, by a little calomel and rhubarb, or some other active purge. Very mild opiates, very cautiously administered, may afterwards prove necessary; but the administration of these in any form to young children requires the utmost caution, and syrup of poppies and other soothing remedies should never be entrusted to the nurse. The period of teething in children cannot be too scrupulously watched over, as the irritation which then ensues seems not unfrequently to lay the foundation of water in the head, especially where there is a predisposition to that disease.

DENUDA'TION. (Lat. denudo, *I lay bare.*) In Geology, the removal of part of the land, so as to lay bare inferior strata.

DENUDA'TUS. (Lat.) Naked. In Botany, applied to the polish or texture of bodies, and denoting the reverse of hairy, downy, or any similar term.

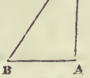
DEO'BSTRUENTS. Medicines which remove obstructions. The term is often used in reference to the removal of glandular complaints.

DE'ODAND. (Lat. Deo dandum, *to be given to God.*) At Common Law, every personal chattel which has been the immediate occasion of the death of a human being is forfeited to the king on the finding of a coroner's inquest; to be applied as alms by his almoner. Where a thing not in motion is the cause of death, it has been held that the part only which was the immediate cause is forfeited; as the wheel of a cart, where a man meets his death by climbing on the wheel at rest and falling from it: if in motion, the whole; as, the whole cart, where the wheel goes over him. However, juries have for a long time past taken on themselves to assess a sum of money, as the value of the thing forfeited; which has become in practice very arbitrary, and usually, but not always, trifling. In this way coroners' juries have to a certain extent usurped a power which the principle of the law by no means entrusts to them; viz. of imposing a fine where they believe negligence to have caused death. By 3 & 4 W. 4. c. 99. s. 29. coroners are to make out and transmit to the treasury an account of deodands.

DEONTO'LOGY. (Gr. δέον, *due*, and λόγος, *discourse.*) The science of duty; a term assigned by the followers of Jeremy Bentham to their own doctrine of ethics, which is founded on the tendency of actions to promote happiness. (See *Bentham's Deontology, init.*; also Mr. Whewell's Preface to *Sir James Macintosh's Dissertation on Ethics*, Edinb. 1836; and art. ETHICS in this work.)

DEPA'RTMENT. (Fr. departir, *to divide.*) In Geography, a territorial division of the kingdom of France. Before the first revolution, France was divided into 37 generalities, or governments, each of which was subdivided according to local custom into districts, bearing various names; and the laws regulating property in each were subject to extremely complicated varieties. The plan of a new division into more convenient portions was first conceived by the Constituent Assembly in 1787, and carried into effect in 1790. Mirabeau proposed the formation of 120 departments; but the actual number formed was 80, afterwards increased by subdivision to 83. M. Belleyme, geographical engineer, was the chief agent in the work. In tracing the limits of the departments, the subsisting divisions of provinces and generalities were maintained to a certain extent; but the chief object was to render them nearly equal on an average repartition of size and population, so that the more populous departments are in general smaller; but the division is by no means uniform. The names of the departments are chiefly taken from rivers, mountains, or other well-known geographical objects. In 1808, the number was increased by conquest to 127, including 12 for the colonies. These last were subsequently retrenched; but in 1811, when the empire extended from Rome to Hamburg, the total number was 130. At present France has 86 departments. Each is administered by an officer named by the government with the title of Prefect, and subdivided into *arrondissments* and *cantons.*

DEPA'RTURE. A nautical term, used to denote the distance a ship has gone to the east or west of the meridian from which she departed. The difference of meridians being first found in degrees, the departure must be estimated by the number of miles in a degree of the parallel of latitude where the ship is. In *Mercator's Sailing*, the departure is represented by the base A B of a right-angled plane triangle, A B C; of which the angle at C opposite the base is called the *course*, and the hypothenuse B C is the *distance sailed.* Hence the theorem for finding the departure: — As radius is to the sine of the course, so is the distance run to the departure.



DEPHLEGMA'TION. The operation of freeing spirit of wine and certain other fluids from the water which they usually contain. A very strong and pure spirit is often said to be highly *dephlegmated.*

DEPHLOGISTICA'TION. (Lat. de, *down*; and Gr. φλογιστος, lit. *burned up.*) A term applied by the older chemists to certain processes by which they imagined that phlogiston was separated from bodies. They regarded oxygen as common air deprived of phlogiston, and hence called it *dephlogisticated air.*

DEPI'LATORY. (Lat. de, *from*, and pilus, *hair.*) Any application which removes hair from any part of the body. The celebrated Turkish Depilatory is a mixture of 7 parts of quicklime and 1 of orpiment. The latter ingredient is probably useless; for when powdered quicklime is made into a thin paste with water, and applied by a camel-hair pencil to any part till it produces a tingling or burning sensation, on wiping it off with a wet sponge the hair, especially if it be soft and delicate, is removed with it.

DEPLOY. (Fr. deployer, *to expand.*) In the art Military, the expansion of a body of troops previously compacted in column, so as to present a larger front; generally for the purpose of performing some evolution, or of forming into line, or of directing an attack in some quarter least expected by the enemy.

DEPORTA'TION. In French law, a punishment equivalent to transportation in English. It is ranked as third in degree; after capital punishment, and condemnation to the galleys or public labour (travaux forcés) for life. Deportation for political offences was a common punishment at one period during the French revolution; especially after the fall of Robespierre and his party. It was then usually executed by conveying the criminals to Cayenne in South America.

DEPOSI'TION. In Law, the testimony of a witness, put down in writing, in answer to interrogatories legally exhibited for that purpose. In the court of chancery such depositions form the established medium of proof; and the interrogatories are exhibited, in London by the examiners, in the country by commissioners appointed for that purpose. Depositions in civil actions, in the courts of common law, are regulated by the stat. 1 W. 4. c. 22. By 7 G. 4. c. 64. the examination of the prisoner and witnesses before a magistrate on a charge of felony must be taken down in writing, and returned to the court. If duly taken, these depositions are evidence at the trial under certain restrictions.

DEPO'T (Fr.), is used to designate a place where all sorts of military stores and provisions are kept, or where recruits are received and trained. It is also applied to that portion of a regiment which remains at home when the rest is ordered upon foreign service.

DEPRE'SSED. (Lat. deprimo, *I depress.*) In Zoology, the whole or part of an animal body is so called when its vertical section is shorter than the transverse.

DEPRE′SSION OF EQUATIONS, in Algebra, is the reduction of equations to a lower degree, by dividing them by one or more of their component factors. It is only in a few cases that equations, whose roots are unknown, can be thus depressed. 1st, When some particular relation subsists between two (or more) of the roots; for example, if an equation contain equal roots these may be found, and the equation reduced as many dimensions lower as there are equal roots. 2d, If two roots of an equation be of the form $+a$, $-a$, differing only in their signs, they may be found, and the equation depressed. 3d, If the equation is reciprocal, that is to say, such that its form is not changed by changing x into $\frac{1}{x}$, then it is susceptible of depression. The methods by which these classes of equations are depressed are to a certain point to be regarded as a branch of the transformation of equations, since the general object of the theory is to make the solution of an equation depend on the solution of another more simple. (See *Bourdon's Algebra.*)

DEPRE′SSION OF THE HORIZON, or DIP OF THE HORIZON, in Nautical Astronomy, denotes the depression or dipping of the visible horizon below the true horizontal plane, and which arises from the circumstance that the eye of the observer is not placed on the same level with the surface of the sea, but at some distance above it. Hence in observing the altitude of the sun or a star above the horizon with the sextant, the altitude appears greater than it really is. Let $a =$ the radius of the earth, and $x =$ the height of the eye above the horizon; then the cosine of the angle of depression $= \dfrac{a}{a+x}$. At the height of 10 feet this amounts to about three minutes of a degree.

DEPUTA′TION (Lat.), is applied to a certain number of persons selected from a company or body, and appointed to lay before a sovereign, an assembly, a minister, or other public functionary, a statement of the views of the selecting party relative to any question, or to prosecute any affair in their name.

DE′PUTIES, CHAMBER OF. The lower of the two legislative chambers in France. The right of election to the Chamber of Deputies is in persons of 25 years of age, paying 200 francs of direct contributions; *i. e.* the land tax, personal tax, door and window tax, and a few others: officers in the army and navy, and members and correspondents of the Institute, are only required to pay 100 francs. The list of electors is made out by the mayors of the communes annually, and revised by the prefect; subsequent claims are judged by the prefect in council, and, in the last resort, by the Cour Royale. There are 459 members of the chamber, each elected by a separate electoral college: the election is by ballot. To be eligible to the chamber, the candidate must be thirty years of age, and pay 500 francs of direct taxes. The total number of electors in 1838-39 amounted to 197,598. The duration of the chamber is triennial.

The Chamber of Deputies is divided into nine bureaux; which are renewed every month. To these bureaux questions are referred by the chamber; as well laws proposed by the king or the house of peers as propositions of individual members. The bureaux report on the question, after separate discussion in each, before the general discussion in the chamber begins. Except in case of dissolution, measures commenced in one section pass on to the next in the same stage in which they have been left. The vote on a proposed law is secret, on any other proposition open.

The "coté droit," "coté gauche," and the "centres," form the three grand divisions of which the Chamber of Deputies is composed. When the three chambers of the States-General of 1789 were consolidated into one by the designation of the National Assembly, the most distinguished members of the aristocratic and republican parties were in the habit of sitting together, for the purpose of communicating more easily with one another: the former occupied the benches to the right, the latter those to the left of the president's chair; while the centre benches, or those fronting the president's chair, were filled by those who held various intermediate shades and modifications of opinion. This custom remains in force at the present day, and nothing can exceed the nicety with which each variety of political opinion is grouped in the French representative assembly. The coté droit, or the side to the right of the president's chair, is occupied by those members who incline to favour the royal prerogative; the coté gauche, on the other hand, is set apart for those who are more in favour of popular ascendency; while those members who, with considerable difference of opinion among themselves, generally support the ministers, occupy the "centres" (centre droit et centre gauche), which may thus be termed the ministerial benches. But, it has been judiciously remarked, "as in every great political party there are shades of opinion, some being more warm and violent, and others more moderate, discriminating, or cautious, so both the coté droit and the coté gauche are generally subdivided into three sections each. The more zealous royalists take their seats at the outer extremity of their side of the house towards the president, and are styled the "extrême droit;" the ultra liberals sit on the corresponding seats on the opposite or left side, and are styled the "extrême gauche." For a more minute view of this arrangement, and an account of the various changes which these different divisions have undergone, see the *Encyclopédie des Gens du Monde*, and the *Penny Cyclop.* art. "Coté Droit."

DE′RBYSHIRE SPAR, *Fluor Spar*. It is of various colours; and the large nodules, which are peculiar to Derbyshire, are often beautifully veined, and admit of being turned in the lathe into vases and small columns. A fine variety of this spar occurs in Cumberland, in cubic crystals of a pale sea-green colour. The cube is the most common form of the crystals of fluor; but it also occurs in octohedra, some fine specimens of which have been found associated with galena in the mine of Beer Alston upon the Tamar. It consists of fluorine and calcium.

DERM. (Gr. δερμα, *skin.*) The true or organized layer of the tegumentary covering of animals. It is composed of a close and irregular network of whitish fibres, consisting of condensed cellular tissue, whence it is also termed "corium," and is every where traversed by capillary arteries and veins, absorbents and nerves; and, in the mammalia, with the roots of the hairs and the ducts of the sudorific follicles: it is covered with the "rete mucosum" and "epiderm." The derm is of considerable thickness in the rhinoceros, hippopotamus, elephant, &c.; whence the name "Pachyderma," applied to the order containing these and allied quadrupeds.

DERMA′PTERANS, *Dermaptera.* (Gr. δερμα, and πτερον, *a wing; skin-winged.*) An order of insects dismembered from the *Orthoptera* of Latreille, and including those which have the elytra wholly coriaceous, and always horizontal; the two membranous wings are folded longitudinally, and the tail is armed with a forceps. This order is represented by a single Linnæan genus, — viz. *Forficula*, or earwig; insects which are common in damp places, and often found in numbers under stones, and beneath the bark of trees: they do much damage in gardens by preying upon the fruit. The English common name, and also the French, "pierce-oreille," relate to a habit absurdly attributed to these insects of penetrating the ears.

DE′RMATOBRA′NCHUS. (Gr. δερμα, and βραγχια, *gills.*) A genus of Gastropods, or snails, in which the branchiæ consist, as in *Scyllæa*, of ramified productions of skin.

DERMATO′LOGY. (Gr. δερμα, and λογος, *a discourse.*) A treatise or history of the skin and its diseases.

DERME′STES. (Gr. δερμα, and εσθιω, *I eat; skin-devourers.*) The name of a Linnæan genus of Clavicorn Coleopterous insects, noted for their ravages on dead animal substances, especially the preserved skins of animals, and which are consequently the pests of a museum. The old genus *Dermestes* is subdivided in modern entomology into several subgenera. The "bacon-beetle" (*Dermestes lardarius*) is the type of that to which the term *Dermestes* is now confined.

DE′RMOBRA′NCHIATES, *Dermobranchiata.* (Gr. δερμα, and βραγχια, *gills on the skin.*) The name of a family of Gastropods, comprehending those which respire by means of external branchiæ or gills, having the form of membranous plates, filaments, or tufts.

DE′RMOSKE′LETON. (Gr. δερμα, and σκελετόν, *the dried remains of a body, or the skeleton; skin-skeleton.*) A term applied to the coriaceous, crustaceous, testaceous, or osseous integument, such as covers most invertebrate and some vertebrate animals; it serves more or less completely the offices of protecting the soft parts of the body, and as a fixed point of attachment to the moving powers.

DE′RRICK, in Nautical language, used in a variety of meanings, but chiefly for a tackle used at the outer quarters of a mizen-yard, consisting of a double and single block connected by a fall.

DE′RVISE. (From a Persian word signifying *poor.*) The name of certain classes of religious persons among the Mohammedans of Turkey and Asia. They live partly in monasteries, partly alone, either stationary or wandering; and belong to a great variety of orders, of which there are thirty-two (it is said) within the Turkish empire only. It is impossible to determine the period to which the origin of the dervises is to be referred. As in most other countries, there has existed in Persia from time immemorial a class of enthusiasts, who, impressed with the conviction that poverty is the only passport to virtue, and that the privations of this world will be commensurately compensated in the world to come, have voluntarily renounced all the comforts, luxuries, and charities of this life, and devoted themselves entirely to religious exercises. In most instances, however, such enthusiasts have been more famed for the theory than the practice of sanctity; and the dervises do not appear to form an exception to the rule. Their public religious

exercises are disfigured by the grossest fanaticism and buffoonery; and their private life is said to be marked by great hypocrisy and licentiousness. (*D'Herbelot, Bibl. Crit.*)

DESCANT. (It. descanto.) In Music, composition in several parts. It is either *plain*, which consists in the orderly placing of many concords answering to simple counterpoint; *figurate* or *florid*, wherein discords are employed; or *double*, where the parts are so contrived that the treble or any high part may be made the bass, and the contrary.

DESCE'NT. In Law, if a person die seised in fee-simple, otherwise than as a joint tenant (see *post*), of lands or tenements which he has not disposed of by will, they will descend to his heir. Such seisin is either actual possession or virtual; as, possession by the tenant of a chattel interest, whose possession is always held to be the same with that of the remainderman, or reversioner, who is to succeed him. If a person have become possessed by purchase of lands or tenements in fee-simple, of which, from the nature of the estate, he cannot obtain seisin (as a remainder expectant on a particular estate of freehold), these likewise descend to the heir in case of his intestacy. It is well known that by the common law of England the rules of descent were different from those obtaining in other countries; that a direct lineal ancestor could in no case inherit from his descendant; that brothers and sisters of the half blood, *i. e.* sprung from another mother, or from another father, were also excluded from the succession. These rules have now (by 3 & 4 W. 4. c. 106.) been wholly removed or modified; so that the law of descent recognizes in succession the following heirs: — 1. The eldest or only son, or his issue. 2. The younger son, or his issue. 3. The daughter, or, if more than one, all the daughters as *coparceners* (see *post*) and their issue; such issue claiming *per stirpes*, not *per capita*, *i. e.* claiming only the share of their respective mothers. 4. In default of lineal descendants, the nearest lineal ancestor now succeeds, in preference to any person who would have been entitled to inherit either by tracing his descent through such lineal ancestor, or in consequence of there being no descendant of such lineal ancestor; *e. g.* a father inherits before a brother, a grandfather before an uncle, &c. 5. In default of father, brothers, or sisters of the whole blood and their issue, then the inheritance devolves on the eldest brother or sister of the half blood by a different mother, the half blood following the same rule where the inheritance devolves on the descendant of any other ancestor. 7. On failure of male ancestors on the paternal side and their descendants, female paternal ancestors and their descendants. 8. On failure of these, the mother, her ancestors, — first male, then female, — and their respective descendants. 9. The half blood follow always next after any relation in the same degree of the whole blood and his issue, if the common ancestor be a male; next after the common ancestor, if a female: so that the brother by the half blood on the part of the mother inherits next after the mother. Descent is always traced from the first purchaser; but the last owner is presumed to be the first purchaser unless the contrary can be proved. In some particular localities the custom of gavelkind prevails, by which all the sons inherit equally from the father. By the custom of borough English, the youngest son is heir. Bastards cannot inherit, nor can an alien; but a natural-born subject may derive his title (under certain restrictions) through alien ancestors.

DESCENT, in Mechanics, is the motion of a body towards the centre of the earth caused by the attraction of gravity. The following are the laws of *descent* of bodies: —

1st. Heavy bodies, in an unresisting medium, fall with a uniformly accelerated velocity.

2d. When the action of gravity is uniform, the space passed over in a given time is exactly half that which would be passed over in the same time by the velocity acquired at the end of the time if continued uniformly.

3d. The spaces passed over in different times are proportioned to the squares of the velocities, or the squares of the times.

4th. The time of the oblique descent of a body down any chord of a circle, drawn from the uppermost or lowermost point of the circle, is equal to the time of descent through the diameter of the circle.

5th. The times of descent through all arcs of the same cycloid are equal.

6th. It is found by experiment that a heavy body near the surface of the earth, when allowed to descend by its own gravity, falls through $16\frac{1}{12}$ feet in the first second of time; consequently, by the 2d law, it acquires a velocity in that time which would carry it through 32 feet in a second, if gravity ceased to act. See ATTRACTION, ACCELERATION.

DESCRI'PTION (Lat. descriptio), in Rhetoric, is used to designate such a strong and lively representation of any object as places it before the reader in a clear and satisfactory light. The execution of this task, as is universally admitted, is attended with great difficulty, and requires no ordinary powers. Indeed, such is the importance which some critics of eminence attach to the possession of this quality, that they have erected it into a standard whereby to estimate the productions of genius in every department of literature; and though such a test may seem somewhat arbitrary, yet when we consider the powers indispensably requisite to form a good description, we shall not be surprised to find that amid the galaxy of brilliant productions in other departments with which our literature is adorned, there are so few authors who have attained eminence in this. A good description, according to Dr. Blair, is simple and concise; it sets before us such features of an object as on the first view strike and warm the fancy; it gives us ideas which a statuary or a painter could lay hold of and work after them — one of the strongest and most decisive trials of the real merits of description. Hence among the qualities essentially necessary, and without which, indeed, even mediocrity is unattainable in this walk of literature, are an eye conversant with nature in all her aspects, a strong imagination wherewith to catch her grand and prominent features, and great simplicity and clearness of style to transmit the impression unimpaired to the imagination of others.

There is no species of composition, prose or poetical, into which description does not enter in some shape; but the term has been borrowed from literature generally, and applied more particularly to those poetical productions which are devoted exclusively to the description of nature, such as Milton's *Allegro* and Thomson's *Seasons*. Hence, although Shakespeare may with great justice be styled a descriptive poet, from the exquisite descriptions of nature with which his unrivalled plays are interspersed; yet as his chief excellence lies in pourtraying the character and passions of man, he does not fall, properly speaking, within this category. By no writer, either of antiquity or modern times, was the faculty of description possessed in a more eminent degree than by Sir Walter Scott. All his delineations of natural scenery are executed with an unrivalled fervour of imagination; while at the same time they are marked by such traits of character and truth that every object is brought distinctly before the mind, and might without difficulty be transferred to canvass by the artist's pencil. Under the head "Descriptive Poetry," in *Blair's Lectures on the Belles Lettres*, the reader will find an admirable account of the characteristics of this species of composition, with a critical notice of the most celebrated descriptive poets of all ages and countries.

DESCRI'PTIVE GEO'METRY. A term first employed by Monge, and subsequently by other French geometers, to express that part of science which consists in the application of geometrical rules to the representation of the figures, and the various relations of the forms of bodies, according to certain conventional methods. It differs from ordinary perspective, inasmuch as the design or representation is made in such a manner that the exact distance between the different points of the body represented can always be found, and consequently all the mathematical relations resulting from the form and position of the body may be deduced from the representation.

In the descriptive geometry, the situation of points in space is represented by their orthographical projections on two planes, at right angles to each other, called the *planes of projection*. It is usual to suppose one of the planes of projection to be horizontal, in which case the other is vertical; and the projections are called horizontal or vertical, according as they are on the one or the other of these planes.

According to this system, any point whatever in space is represented by drawing a perpendicular from it to each of the planes of projection: the point on which the perpendicular falls is the projection of the proposed point. As contiguous points in space form a line, so the projections of those points, which are also contiguous, form a line in the same manner, which is the projection of the given line. Hence as two projections only are required for the determination of a point in space, they are also sufficient for the determination of any curve whatever, whether of single or double curvature.

The same mode of representation cannot be employed with regard to surfaces; for as the projections of the contiguous points of a surface cover a continuous area on both planes of projection, there is nothing to indicate that any particular point on one of the planes of projection corresponds to one point more than another on the second plane, and consequently that it belongs to one point more than another in space. But if we conceive the surface which is to be represented to be covered with a system of lines succeeding one another according to a determinate law, then, by projecting these lines on each of the two planes, and marking the correspondence of the one projection with the other, the projections of all the different points of the surface will have an evident dependence on

each other, and the surface will be rigorously and completely determined.

Some elemenatry surfaces may, however, be represented in a much more simple way. The plane, for example, is completely defined by the straight lines in which it intersects the two planes of projection. These lines are denominated the *traces* of the plane. A sphere is also completely defined by the two projections of its centre, and the great circle which limits the projections of its points. A cylinder is defined by its intersection (or trace) with one of the planes of projection, and by the two projections of one of its ends. A cone is represented by its intersection with one of the planes of projection and the two projections of its summit.

The most immediate application of descriptive geometry is the representation of bodies, of which the forms are susceptible of a rigorous geometrical definition. Sculpture, architecture, painting, and all the mechanical arts, the object of which is to give to matter certain determinate forms, borrow from descriptive geometry their graphical procedures, by the aid of which all the parts of an object are faithfully represented in relief before the object itself is executed. But it was chiefly in consequence of its application to civil and military engineering, and to fortification, that this branch of geometry received a distinctive appellation, and was considered of so much importance as to form one of the principal departments of study in the Polytechnic school of France. The best systematic works written on the subject are those of Monge, Hachette, Vallée, and Leroi. A good general idea of the methods of procedure may be obtained from the small work of Lacroix, *Complément des Elémens de Géométrie.*

DE'SERT. (Lat. desertum.) A term generally used to designate an uninhabited place or solitude; in which sense, as has been judiciously remarked, it is equally applicable to the fertile plains watered by the Maranon, and the sandy wastes of Lybia, but applied more particularly to the vast sandy and stony plains of Africa and Asia. In every region of the globe plains are to be found of greater or less extent, which, though marked by strong features of resemblance in their grand outlines, exhibit with the different latitudes in which they are placed a corresponding variety of character, and according to the distinguishing peculiarities of each are known by different appellations. Thus we have the *steppes* of Europe, the *deserts* of Asia and Africa, the *savannahs* of the Mississippi and the Missouri, and the *pampas* and *llanos* of South America. (See these different articles.)

The most striking feature of Africa consists of its immense deserts, which have in all ages presented to the speculations of the geographer objects highly worthy of attention. Of these the chief is the *Sahara*, or *the Desert*, so called by way of eminence. This prodigious zone of sand stretches, with few interruptions, from the shores of the Atlantic to the confines of Egypt, and comprehends in its length and breadth a superficies of about 2,200,000 square miles. The sand raised by the burning wind called the simoom is frequently in a state of motion, and as it sweeps along in its career of desolation bears a strong resemblance to the waves of a tempestuous sea. This immense expanse, however, is by no means a uniform surface of loose sand. In many parts the dreary waste is broken by low hills of naked sandstone, or by tracts of arid clay, and occasionally it is enlivened by verdant isles or *oases*, which serve as resting places for the caravans that traverse these dismal regions. (*Traill's Physical Geog.*) But for these *oases*, indeed, the Sahara would be wholly impassable. It presents, says Malte Brun, no traces of a beaten path; and the caravans that traverse it, directing their way by the polar star, describe a tortuous road in order to profit by the oases, which are represented as brilliant with vegetation, but which probably owe a great part of their reputation to the contrast they form with the absolute barrenness of the desert.

As we have elsewhere remarked (*see* CAMEL and CARAVAN), the camel is the sole medium of the communication between those countries which are separated by extensive deserts. In the beautiful and expressive metaphor of eastern speech, it is "the ship of the desert;" and in truth it is the only ship by which the wilderness can be navigated with certainty and safety.

The great deserts of Africa are only separated from those of Asia by the valley of the river Nile and the Red Sea. But upon this subject we cannot refrain from transferring to our columns the remarks of Dr. Traill, who has sketched with a masterly hand the grand outlines of the Asiatic deserts. "Soon after quitting the Nile, the traveller by the route of Suez encounters sand, which is continued into the centre of Arabia, where it forms the desert of Nedsjed, extending to the valley of the Euphrates. The sandy zone then inclines northward, enters Persia, and forms the saline deserts of Adjemi, Kerman, and Mekran; it is turned north-east by the valley of the Indus, passes through Caubul and Little Bukharia, till it joins the vast deserts of Cobi and Shamoo, which occupy so large a portion of Central Asia between the Altalan and Mustag chains, and reach to the confines of China. The sandy zone, thus traced throughout the breadth of the ancient continent from Western Africa to the 120° of east longitude, has been computed to cover an area of 6,500,000 square miles; but the Asiatic portion of this tract includes many chains of mountains and fertile valleys. It is characterized by the occurrence of arid wastes of sand or clay, sometimes with saline incrustations on the surface, and is remarkably deficient in considerable rivers: except the Nile, the Euphrates, the Indus, and the Oxus, there are no large rivers in a region which embraces almost a fourth part of both Africa and Asia. This portion of Central Asia forms a series of elevated plains 6000 miles in length from east to west. Some of these plains, says Humboldt, are covered with herbage; others produce only evergreen saliferous plants, with fleshy and jointed stems; but a great number glitter from afar with a saline efflorescence that crystallizes in the semblance of lichens, and covers the clayey soil with scattered patches like new-fallen snow." (*Physical Geog.* pp. 21, 22.) Under the head MIRAGE will be found some account of the so called singular optical illusion so often seen in the desert.

In Scripture, the term desert bears a wholly different interpretation from that usually attached to it in profane writings. It has been fully shown by Reland (*Palest.* l. i. p. 375.) that the Hebrew מדבר (midbar), the ἐρῆμος of the Greeks, and the *desertum* or *solitudo* of the Latins bear no analogy to each other; the first being appropriated almost exclusively to those thinly peopled districts of the Holy Land which yielded pasturage for cattle, and were remarkable at once for their beauty and the luxuriance of their vegetation.

DESE'RTER. (Lat.) An officer, soldier, or sailor, who absents himself from his post without permission, and with the intention not to return. The crime of desertion has in all ages and countries been regarded with peculiar detestation. In Greece and Rome, the deserter, during war, suffered death; during peace, was deprived only of civil rights: a sound and enlightened distinction. The military code of Great Britain inflicts "death or such other punishments as may be adjudged by a general court-martial" on deserters; thus leaving a proper discretionary power for the exercise of lenity in cases where the motives to the crime may bear the most favourable construction.

DESICCA'TIVES. (Lat. de, and siccus, *dry*.) In Materia Medica, applications which dry up the secretion of membranes, ulcers, &c.

DESIDERA'TUM (Lat. *wished for*), is used to signify something wanted to improve or perfect any art or science, or to promote the advancement of any object or study whatsoever.

DESI'GN. (Fr. dessin.) In all the Arts, the idea formed in the mind of an artist on any particular subject, which he endeavours to transfer to some medium for the purpose of making it known to others. It is sometimes loosely and improperly used synonymously with drawing.

Every work of design is to be considered either in relation to the art that produced it, to the nature of its adaptation to the end sought, or to the nature of the end it is destined to serve; thus its beauty is dependent on the wisdom or excellence displayed in the design, on the fitness or propriety of the adaptation, and upon the utility of the end. The considerations of design, fitness, and utility, have become the three great sources of beauty of form. This beauty frequently arises from the combined power of these expressions.

Every work of art supposes unity of design, or some particular end proposed by the artist in its structure or composition. In forms considered simply as expressive of design, the only possible sign of unity of design is uniformity or regularity, by which the productions of chance are distinguished from those of design; and without the appearance of this, variety becomes confusion. In every beautiful work of art, we are not satisfied with mere design, — we must have elegant design, of which the grand feature is variety; it is this which in general distinguishes beautiful from plain forms, and without it uniformity is dull and insipid.

The arts of design are usually considered those of Painting, Sculpture, and Architecture; to which, under their several heads, the reader is referred for further information.

DESI'GNA'TOR. (Lat.) In Roman Antiquities, a species of master of the ceremonies, whose duty it was to assign to each person his proper place in the theatres and at the other public spectacles. Officers with this appellation were employed among the Romans on every occasion of public display, and in all domestic solemnities whether of a joyful or mournful character. But the chief occupation of the *designator* consisted in arranging and marshalling the funerals of distinguished persons; and in this capacity he was attended by a troop of inferior officers, all arrayed in black, whose part it was, among other duties, to keep off the crowd, like the lictors of the magistrates. In his brief and elegant description of the

insalubrity of Rome during the autumnal season (*Epis.* i. 7.), Horace thus graphically introduces the designator and his attendants: —

—— dum ficus prima calorque
Designatorem decorat lictoribus atris.

DE'SPOT. (Gr. δεσπότης, *master*.) A name applied to sovereign princes possessing absolute authority. The well-known address of the slave to Hippolytus, in *Euripides* — "O king, for it is fitting to call only the gods despots" (*masters*) — shows the distinction which the republican spirit of the Greeks took between the two titles. The later Greek emperors took the title of despot: which was afterwards, about the eleventh century, given to the son or nearest relation of the reigning prince.

DE'SPOTISM. In Politics, absolute and irresponsible government by a single individual or despot. In popular language, all governments are called despotical that are administered by one individual whose decisions are not controlled by any representative assembly or recognized subordinate authorities. Thus, we are in the habit of saying that the emperors of Austria and Russia and the king of Prussia are despotical or absolute sovereigns; meaning by this, that all legislative and executive measures seem to proceed from their free will. But the abstract idea of despotism goes farther than this; and means a government by a single individual with unlimited power over the lives and fortunes of his subjects. The prophet Daniel, in his description of the Babylonian monarch Nebuchadnezzar, has given what is perhaps the best account of this species of government. "All people, nations, and languages, trembled and feared before him: whom he would he slew, and whom he would he kept alive: whom he would he set up, and whom he would he put down." (Chap. v. 19.)

But though this gives a vivid idea of what is understood by a pure depotism, it can be regarded only as a popular, or rather poetical account, of a government where the sovereign is possessed of great power. The truth is, that a purely despotical government never had, and never can have, any existence in fact. How absolute or despotical soever, all sovereigns must conduct their government so as to procure the concurrence and support of a large, or, at all events, a powerful portion of their subjects. A despot is, after all, merely an individual, and becomes quite powerless when those masses of individuals, in whom the ability to coerce others really resides, disapprove of his proceedings. The prætorian bands in antiquity, the janissaries of Constantinople, and the grenadiers of Petersburg, must, at least, be led by opinion. But though the sanction of the instruments employed in his government be indispensable to the existence of a despot, it is but seldom that he dares trust to it only. The most absolute and tyrannical of the Roman emperors, when they wished to get rid of any obnoxious individual, dared not to order him to be executed, but were obliged to suborn false evidence, and to proceed against him according to legal forms: and so it is in all countries. Were the most absolute sovereign of whom we have any certain accounts openly to seize on the property of any individual in his dominions, or to put him to death without being able to assign some apparently satisfactory grounds for doing so, the foundations of his power would be shaken to the very centre; and the repetition of such conduct would most likely occasion his deposition. The strength of absolute governments, when they embark in oppressive courses, depends on their being able to conceal or pervert the real facts of the case, so that the victims of their tyranny may be made to appear to be the victims of their justice. We may be assured that no ruler of any country emerged from the merest barbarism ever could, for any considerable period, openly commit on his own responsibility any gross injustice towards any considerable portion of his subjects. Those who have done so have rarely, if ever, failed to expiate their folly and tyranny by some signal punishment.

Neither the government of Prussia nor Austria, nor even that of Russia, can be justly called despotical. Their rulers are controlled to a very great extent by the force of public opinion; and are influenced by a much more lively feeling of responsibility than the sovereigns of limited monarchies, or of countries in which the legislative functions are divided. It is this fear of their subjects that makes them so anxious, by laying restrictions on the freedom of the press, to conceal their conduct, or to obtain a favourable judgment upon it. There can be no despotism, nor any considerable approach towards despotical government, where the press is free and the people instructed; and it is to their influence in securing the freedom of the press, and consequently in enlightening public opinion, and making the bulk of the people acquainted with their *real* interests, that the advantage of representative assemblies and of a popular form of government is mainly to be found.

DESQUAMA'TION. (Lat. squama, *scale*.) The separation of layers or scales from the skin or bones.

DESSE'RT. A word of doubtful etymology, signifying the last service at dinner, consisting of fruits and confections, &c. The modern dessert is probably equivalent to the *mensæ secundæ* of the Romans. If we believe Congreve, the term came into use among the French about the commencement of the 17th century, and was soon adopted into and naturalized in most of the European languages. In all the countries of Europe the splendour of the dessert has ever since the period of its introduction kept pace with the progress of refinement and civilization, and by many *gastronomes* the qualities and arrangement of a dessert are looked upon as the most valid test of all that is Attic in taste and refined in elegance.

DESTE'MPER. (Fr. détrempe.) In Painting, a preparation of opaque colour ground up with size and water, used in scene painting. This species of painting is also called, when practised on a small scale, *body colour painting*. Destemper painting differs from fresco painting in that the latter is performed while the walls are still wet, whilst the former requires that they should be dry.

DE'STINY. (Lat. destinare, *to appoint*.) An inevitable necessity depending upon a superior cause. This doctrine has, under a variety of names, been embodied in almost all the religious systems of antiquity; and even in modern times, with a few modifications, it has been largely adopted by many sects of the Christian church. (*See* PREDESTINATION, NECESSITY.) Destiny was called by the Romans *Fatum* (*see* FATES), and by the Greeks Αναγκη, *Necessity*, or Μοιρα, *a Part*, as if it were a chain or necessary series of things indissolubly linked together. According to many of the heathen philosophers, destiny was a secret and invisible power or virtue, which with incomprehensible wisdom regulated all the occurrences of this world which to human eyes appear irregular and fortuitous. The Stoics, on the other hand, understood by destiny a certain concatenation of things, which from all eternity follow each other of absolute necessity, there being no power able to interrupt their connection. (*Rees's Cyclo.*) To this invisible power even the gods were compelled to succumb. Jupiter and Venus are represented by the poets as vainly attempting to withdraw Cæsar from his impending fate; but, as Seneca observes, it is thus that the Ruler of all things, in writing the book of destiny, has prescribed the limitation of his own power: "Scripsit fata; sed sequitur, semper paret."

DESTRU'CTIVE DISTILLA'TION. A term applied to the distillation of organic products at high temperatures, by which the ultimate elements are separated or evolved in new combinations. The destructive distillation of coal is resorted to for the production of gas, and that of bone for the production of ammonia, and of wood for the formation of vinegar.

DETA'CHED. (Fr. detaché.) In Painting, a term applied to all objects in a picture which appear to stand out from those by which they are surrounded. It arises from a due knowledge of aërial and linear perspective.

DETA'CHMENT (Fr. detachement), in Military language, is a certain number of squadrons of cavalry and battalions of infantry, selected from the main body of an army for the purpose of being employed in some particular duty, such as in *foraging*, *escorting*, &c.

DETA'ILS. (Fr. detail.) In the Fine Arts, the parts of a work as distinguished from the whole as a mass. They must always be so kept under as not to interfere with the general effect of the work; neither must they be overlaboured, lest, instead of aiding, they embarrass the work of which they form parts.

DETE'NTS, in Clock-work, are the stops which lock and unlock the machinery in striking.

DETE'RGENTS. (Lat. detergo, *I wipe away*.) Medicines which remove viscidity, and cleanse sores.

DETE'RMINATE PRO'BLEM. In Geometry, is a problem which admits of one solution only, or a limited number of solutions; and is opposed to an *indeterminate problem*, which admits of an indefinite number of solutions.

DETERMINA'TION OF BLOOD. In Medicine and Surgery, when there is apparently a more copious and rapid flow of blood to any part, it is said to suffer under a determination of blood; as to the brain, liver, &c.

DE'TINUE, in Law, is a personal action of contract, and lies where a party seeks to recover goods and chattels, or deeds and writings, detained from him.

DE'TONATING TUBE. A stout glass tube used in the chemical laboratory for the detonation of gaseous bodies. It is generally, as represented in the annexed cut, graduated into centesimal parts, and perforated by two opposed wires, for the purpose of passing an electric spark through the gases which are introduced into it, and which are confined within it over water or mercury. When a detonating tube is used over either of these fluids, the smallest possible quantity of explosive gas should be introduced into it, as in consequence of the expansion which ensues, a portion is apt to be forced out at the moment of the explosion. The tube, when used, should be firmly held; a spring is sometimes substituted for the grasp of the hand, but it is inconvenient.

DETONA'TING POWDER. A term applied in

Chemistry to fulminating mercury and silver, and to other compounds which suddenly explode when struck or heated. Some of these compounds have lately been much used for the ignition of gunpowder in percussion locks.

DETONA'TION. When chemical combination or decomposition is sudden and attended by flame and explosion, it is often said to be effected by *detonation*. If a mixture of hydrogen gas and oxygen be inflamed by the electric spark or by a taper, it burns rapidly and with explosion, and is said to *detonate*. When a grain or two of phosphorus is mixed with chlorate of potassa and struck with a hammer, the mixture detonates.

DETRI'TUS. A geological term applied to deposits composed of various substances which have been comminuted by attrition. The larger fragments are usually termed *debris;* those which are pulverized, as it were, constitute *detritus*. Sand is the detritus of siliceous rocks.

DEUCA'LION. One of the most famous personages of antiquity, the son of Prometheus, and king of Thessaly. The story of the deluge with which Thessaly was inundated during his reign, the preservation of Deucalion with his wife Pyrrha, and the mode by which, in compliance with the injunction of the oracle, they repeopled the world, are too well known to require being dwelt upon in this place. The grand features of the flood of Deucalion, which, as recorded by Ovid and other writers of antiquity, bear so striking a resemblance to the scriptural account of the deluge, are common to the history or the traditions of almost all nations, how remote or barbarous soever. The great Indian poem, *Mahabarada*, for instance, contains a graphic description of a flood, by which, with two exceptions, the whole human race was overwhelmed; and M. Humboldt found on the banks of the Orinooko a similar tradition, which had prevailed among the barbarous natives from time immemorial. In that beautiful ode dedicated to Augustus (Book 1, 2.), in which richness of imagery and elegance of language vie with the loftiest tone of morality, Horace thus alludes to the flood of Deucalion: —

> Terruit gentes, grave ne rediret
> Sæculum Pyrrhæ nova monstra quæstæ,
> Omne cum Proteus pecus egit altos
> Visere montes, &c.

The date assigned to Deucalion by Eusebius is 1541 B.C., by the Parian marbles seven years earlier; but many of the statements concerning him are so obscure, while others are so manifestly mythological, as to leave considerable doubts of his having ever existed. *See* DELUGE.

DEUS EX MACHINA. A scholastic expression, borrowed from the stage. In conformity with the mythological belief of the age, the tragic poets of Greece, and especially Euripides, instead of bringing about their catastrophe by natural means, often resorted to a more convenient expedient — the intervention of a divinity. But when any such intervention, contrary to the maxim ot Horace,

> Nec deus intersit nisi dignus vindice nodus,

took place without an adequate cause, it was injurious to scenic effect; and hence the expression *deus ex machina* originated, the divinity in such a case being nothing more than a *machine*. This expression has also been applied by analogy to those philosophers who, unable to solve a difficulty by ordinary means, have immediate recourse to the aid of a supernatural power.

DEU'TERONOMY. The name given to the last book of the Pentateuch. The term is composed of two Greek words, δευτερος, *second*, and νομος, *law;* and is equivalent to the *Mischna* of the Hebrews, who thus designated the book of Deuteronomy, from its containing a recapitulation of the laws and ordinances scattered over the other books of Moses. *See* PENTATEUCH.

DEUTEROPA'THIA. (Gr. δευτερον, *second*, and παθος, *disease*.) A sympathetic affection of any part; as a headache from an overloaded stomach, or sickness from an injury of the head.

DEU'TOXIDE. A term applied in Chemistry to certain compounds containing *one* atom or prime equivalent of base in combination with *two* of oxygen; in this sense the word is synonymous with *binoxide*. It is sometimes indiscriminately applied to the second degree of oxidizement of which bases are susceptible.

DE'VIL. (Gr. διαβολος, *an accuser*), lit. one "who accuseth us before God day and night." (Rev. xii. 10.) The word bears the same sense as Satan, and is applied in the New Test. to the evil principle, the adversary of man referred to throughout the books of the Old and New Test. under various names and titles, as Satan, Lucifer, Belial, Apollyon, Abaddon, the Man of Sin, the Tempter; and described as an angel who fell from heaven with many inferior spirits, being cast down from thence by God for his pride and rebellious spirit. From that time he is said to have had permission to try and tempt mankind, in which he succeeded in the persons of our first parents, thereby introducing sin and sorrow into the world. He is represented in Job and Zechariah as standing in the presence of the Lord, seeking permission to tempt men. It is manifest that the character herein attributed to the Devil is identical with that of the Evil Principle in the Gnostic and Manichean philosophy, and in the oriental system of religion generally; excepting, indeed, that the scriptures always maintain the inferiority of the evil to the good; but it may also be reasonably inferred that it was held by the Jews anterior to their captivity in Babylon, and the contact into which they then came with the Magian superstitions. Although the serpent who tempted Eve in Paradise is not expressly said to be this Satan or Devil, nor is he at all mentioned by name by Moses, yet the character of the Evil Principle is there vividly delineated; he is also characteristically mentioned in the Psalms, the Book of Job, and the Chronicles.

DEVI'SE, or DEVICE. (Fr. deviser, *to invent, will*, or *imagine*.) In Heraldry, the term Devise is popularly used in the same sense as armorial bearings (which see); but it is more strictly employed to signify a symbol, consisting of a representation of some visible object, and in many instances a motto appropriate to it, used, not by way of heraldic bearing, but according to the fancy of the inventor: sometimes for the motto alone. Monograms are also a species of device. From the word *deviser*, in its ancient signification of *to will*, is derived the Norman French *devise*, a bequest of real property by testament, which is still retained in our law.

DEVISE, in Law, is a gift of lands by a last will and testament. Lands held in fee-simple became devisable, where not so by special custom, by the statute 34 & 35 H. 8. c. 5. By 3 & 4 W. & M. c. 14. devises were made void against specialty creditors. Estates pur auter vie are devisable by stat. 29 C. 2. c. 3. A will of lands formerly only operated on those lands of which the testator was possessed at the time of publishing it. (*See* WILL.) In a devise, the words are, in general, more liberally construed than in alienation by deed. But by the recent Statute of Wills (1 Vic. c. 26.) every will is held to speak, both as to real and personal property, as if executed immediately before the death of the testator.

DEW. (Germ. thau, *moisture*.) The deposition of water from the atmosphere, occasioned by cold. The phenomena of dew have been considered by all writers on meteorology, from Aristotle downwards; but they were first successfully investigated by the late Dr. Wells, who gave the true theory of the meteor in an admirable essay on the subject, first published in 1814.

The circumstances which influence the production of dew are the following: — Dew is never abundant except during calm and serene nights. It is, however, frequently observed in small quantities both on windy nights, if the sky is clear, and on cloudy nights, if there is no wind; but it is never seen on nights both cloudy and windy at the same time. If, in the course of the night, the weather, from being calm and serene, should happen to become windy and cloudy, not only will no more dew be formed, but that which has been already formed will disappear, or at least diminish considerably. In calm weather, if the sky be partially covered with clouds, more dew will appear than if it were entirely covered, but less than if it were entirely clear. A slight motion of the air is rather favourable than otherwise to the formation of dew. On two nights equally calm and serene, the quantities of dew deposited may be very unequal. If rain has fallen recently, it will be formed in abundance; on the contrary, very little will be formed in nights otherwise favourable, if the weather has been dry for some time previously. In general, whatever tends to increase the quantity of moisture in the atmosphere will contribute to render the deposition of dew more abundant. Dew is commonly more plentiful in spring and autumn than in summer; the reason is, that the differences of the temperatures of the day and night are greater in the former seasons of the year than in the latter. It is always most copious on those clear and calm nights which are followed by misty or foggy mornings; the formation of the fog showing that the atmosphere had previously contained much moisture. Dew has been observed to be unusually plentiful on a clear morning succeeding a cloudy night. The notion that dew is only formed in the morning and evening is incorrect; bodies are covered with dew at all hours of the night, provided the sky be serene. In this country dew probably begins to appear upon grass, in places shaded from the sun during clear and calm weather, soon after the heat of the atmosphere has declined; that is, three or four hours after midday. Grass is frequently felt to be moist, in dry weather, several hours before sunset; but, on the other hand, dew is scarcely ever known to be present in such quantity upon grass as to exhibit visible drops before the sun is very near the horizon, or to be very copious till some time after sunset. Other circumstances being equal, less dew is formed during the first half of the night than during the second, although the air at midnight has already lost a certain portion of its moisture.

Polished metals are, of all bodies, those which attract the least quantity of dew. This property of metals is sufficiently remarkable to have led some respectable philosophers to affirm that they are never wetted by dew.

Dr. Wells, however, observed it to form on gold, silver, copper, tin, platina, iron, steel, zinc, and lead; but when dew does form on these metals, it commonly only sullies the lustre of their surfaces; and even when it is sufficiently abundant to gather into drops, these are almost always small and indistinct. Dew which has been formed upon a metal will often disappear, while other substances in the neighbourhood remain wet; and a metal which has been purposely wetted will often become dry, though similarly exposed with bodies that are contracting dew. This inaptitude of the metals to attract dew is communicated to bodies of a very different nature which touch or are near them: for example, wool laid upon a metal will acquire much less dew than an equal quantity laid upon grass in the immediate vicinity; and, conversely, bodies on which the metals are laid have an influence on the quantity of dew which the latter will attract. The metals do not all resist the formation of dew with the same force. Dr. Wells one night saw platina distinctly dewed, while gold, silver, copper, and tin, though similarly situated, were entirely dry; and he several times saw these four metals free from dew, while iron, steel, zinc, and lead were covered with it.

Difference in the mechanical state of bodies, though the other circumstances be similar, has an effect on the quantity of dew which they attract. Thus, more dew is formed upon fine shavings of wood, than upon a thick piece of the same substance. It is chiefly for a similar reason that fine raw silk, fine unwrought cotton and flax, were found by Dr. Wells to attract somewhat more dew than the wool he employed, the fibres of which were thicker than those of the other substances just mentioned.

The quantity of dew which is precipitated on bodies does not depend solely on their nature and constitution, but also on the situation in which they are placed with regard to surrounding objects. As a general principle, it may be affirmed that whatever tends to diminish the portion of the sky which can be seen from the place which the body occupies, diminishes the quantity of dew with which the body will be covered.

Of the Cold connected with the Formation of Dew.—The temperature of grass covered with dew is always lower than that of the surrounding air. On calm and clear nights, Dr. Wells very frequently found the grass 7, 8, or 9 degrees, and on one occasion 14 degrees, colder than the air about 4 feet above the ground. He also observed that in places sheltered from the afternoon sun, but still open to a considerable portion of the sky, the difference between the temperature of the grass and the air begins to be sensible as soon as the heat of the atmosphere begins to diminish. In analogous circumstances, a similar coldness continues on grass, in still and serene mornings, for some time after the rising of the sun. In cloudy nights, particularly if there was wind, the grass was never much colder than the air; sometimes it was even warmer: but in calm weather, very high clouds, though sufficiently extensive and dense to conceal the sky, would yet frequently allow of the grass being several degrees colder than the air. If the night became cloudy, after being very clear, the temperature of the grass immediately became higher. The temperature of metals sometimes falls from 2 to 4 degrees below that of the surrounding air; when this takes place, other bodies, such as wool, swan-down, the leaves of plants, &c., are considerably colder than the atmosphere. The substances which are most easily covered with dew are those which are cooled down the quickest when exposed to a clear sky. Of all substances tried by Dr. Wells, swan-down exhibited the greatest cold; in general, the most productive of cold are the filamentous and downy. Snow, also, is one of those bodies which acquires a temperature very considerably lower than the atmosphere.

Theory of Dew.—Dr. Wells's experiments show that the most perfect analogy subsists between the faculty which bodies possess of attracting moisture from the atmosphere, and the other property which they have of acquiring, in calm and clear nights, a temperature much below that of the surrounding air. But is the cold which is observed on bodies covered with dew the cause or the consequence of the precipitation of the fluid? The latter opinion was maintained by Dr. Wilson of Glasgow, in a paper on hoar-frost inserted in the first volume of the *Transactions of the Royal Society of Edinburgh*. But it has been clearly established by Dr. Wells that the cold is the cause of the dew; for he found, 1st, that in certain circumstances bodies would become colder than the air without being dewed, whence it is obvious that the cold could not be the effect of the dew; and, 2d, that when dew was formed, its quantity and the degree of cold that appeared with it, at different times, were very far from being always in the same proportion to each other. He also invariably found that bodies became colder before dew began to appear on them. The formation of dew is therefore a phenomenon precisely of the same kind as the precipitation of moisture which takes place on the outside of a vase into which a liquid colder than the air is poured. But this is a phenomenon of which the most complete and satisfactory explanation has been given. It is well known that atmospheric air, at every different degree of temperature, can contain only a determinate quantity of water, and that the quantity is greater as the temperature is higher. Conceive then a stratum of air coming into contact with a solid body colder than itself: the contact cools it down to a lower temperature, and immediately a portion of its water is precipitated. A second stratum of air succeeds the first, is cooled down in its turn, and abandons that portion of its moisture which its decreased temperature does not permit it to retain. The phenomenon is repeated with great rapidity, and in a short time the *cooling* body is covered with small drops, or even a continuous sheet of moisture. As soon as it was proved that bodies exposed to the clear sky acquire a temperature lower than that of the atmosphere, the origin of the moisture with which their surfaces become covered could not be mistaken.

In order to render this theory complete, it only remains to explain the cause why bodies, when exposed to the sky in clear and calm nights, become colder than the surrounding atmosphere. Since the laws of the radiation of heat were established by the experiments of Sir John Leslie and Count Rumford, the rationale of this phenomenon has been well understood. During calm and serene nights, the upper parts of the grass radiate their heat into the regions of empty space, from which they receive back no heat in return; its lower parts, from the smallness of their conducting power, transmit little of the earth's heat to the upper parts, which at the same time receiving only a small quantity from the atmosphere, and none from any other lateral body, must remain colder than the air, and condense into dew its watery vapour, if this be sufficiently abundant, in respect of the decreased temperature of the grass.

This explanation is grounded on the hypothesis of M. Prevost of Geneva respecting the constant radiation of heat by bodies in contact with the atmosphere, even at the time when they are exposed to the influence of bodies warmer than themselves: but the hypothesis has not been universally admitted; and Sir J. Leslie, on the contrary, ascribes the effect to the descent of cold air from the upper regions of the atmosphere. "The application of the æthrioscope," he remarks, "has not only ascertained the existence, but measured the intensity, of the cold pulses which are at all times darted downwards from the successive strata of air, though often partially intercepted by clouds, or more completely obstructed by low fogs. It may be computed that in fine bright evenings those cold pulses, rained from the sky, are sufficient alone to depress the temperature of the ground, according to the seasons, sometimes eight degrees, but generally about three degrees of Fahrenheit's scale. The blades of grass, thus chilled from exposure, cool in their turn the damp air which touches them, and cause it to drop its moisture." (*Ency. Brit.*, art. "Dew.") The theory of Dr. Wells has also been examined by Mr. Blackadder, in the *Edinburgh Philos. Journal*, Nos. XXI., XXVII., and XXVIII.; and more recently by Van Roosbroek of Leyden in his *Théorie de la Rosée*, Rotterdam, 1836.

It may be added, that among all the phenomena connected with the formation of dew, there is not one which does not admit of a satisfactory explanation on the principle established by Dr. Wells; namely, that dew is never deposited on the surface of bodies till they have been previously cooled down by their radiation towards space.

DEW'BERRY. The fruit of the *Rubus cæsius*, so termed from the resemblance of the bloom or waxy secretion upon it to dew.

DEW POINT. The degree indicated by the thermometer when dew begins to be deposited. It varies with the degree of the humidity of the atmosphere.

DEXIA'RIÆ. A family of Dipterous insects, which subsist chiefly on the juices of flowers. The typical genus is *Dexia*, Mirgen; the other genera included in the family are *Zeuxia, Dinera, Scotiptera, Rutila Gymnostyla, Omalogaster*, and *Prosena*.

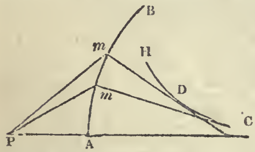
DE'XTRINE, in Chemistry, means the soluble or gummy matter into which the interior substance of starch globules is convertible by *diastase*, or by certain acids. It is remarkable for the extent to which it turns the plane of polarization to the *right* hand, whence its name. The term is also applied to starch which by exposure to heat has been rendered soluble in cold water.

DEY. (Derived by some from the Turkish daï, *a maternal uncle.*) A Turkish title of dignity, given to the governors of Algiers (before the French conquest), Tunis, and Tripoli. The dey is chosen for life from among the chief authorities of the place, with the approbation of the Turkish soldiery. At Tunis the equivalent title of *bey* is more usually substituted for *dey*. This term is admitted by all philologists to be of very great antiquity; though it is impossible to assign any precise date to its introduction. The reader will find in *Ersch and Gruber's Encyclop.* much valuable information respecting this title, and the regencies in which it is in use.

DIABE'TES. (Gr. δια, *through*, and βαινομαι, *I pass.*)

An immoderate flow of urine. There are two varieties of this disorder: the one is merely a superabundant discharge of ordinary urine, and is termed *diabetes insipidus;* in the other the urine has a sweet taste, and contains abundance of a peculiar saccharine matter: it is called *diabetes mellitus.* This disease usually attacks persons of a debilitated constitution towards the decline of life, and generally without any obvious cause. Thirst and a voracious appetite are its first symptoms; the urine gradually increases in quantity; and then there is a sense of weight and uneasiness in the loins, emaciation, œdematous legs, and hectic fever. The quantity of urine which is voided sometimes far exceeds that of liquid and solid food taken together; so that it has been supposed that the solids of the body are, as it were, melted down, and flow off in the form of water and sugar. In diabetes mellitus the quantity of saccharine matter is generally such, especially where the disorder has been of long standing, as materially to increase the specific gravity of the urine; and this accordingly forms a useful criterion of the state of the disease, for whatever tends to diminish the specific gravity of the urine is at the same time diminishing its saccharine contents: an hydrometer therefore is useful in determining this point. The specific gravity of healthy urine does not exceed 1020, and contains about 380 grains of solid matter in the pint; that of diabetic urine sometimes attains a specific gravity of 1040 to 1050; in which case, as appears from Dr. Henry's table (*Medico-Chirurgical Transactions*, vol. ii.), it contains from 766 to 960 grains of solid matter in the pint. The cause of this disease is unknown; but it has been shown that there are no traces of sugar in the blood of persons who are voiding it abundantly by urine; so that the idea of its formation in the stomach, and subsequent separation in the kidneys, is untenable. Nor has dissection thrown much light upon the subject, for in some cases no morbid state of the viscera is observed; in others, however, the kidneys are flabby, pale, and enlarged, or more vascular than they should be: the lacteals are also sometimes thickened, and the mesenteric glands enlarged. There are very few cases on record of the cure, or even of the relief, of confirmed diabetes. Where it is symptomatic of hysteria, dyspepsia, or hypochondriasis, the usual remedies for those affections are useful; but where it is *idiopathic*, and saccharine, nothing has proved decidedly serviceable. Strict abstinence from vegetable food of every kind, and the free exhibition of opium, are the only plans which have held out hopes of success; but there are very few cases upon record in which these seem to have been permanently successful.

DIACAU'STIC CURVE (Gr. δια, *through*, and καιω, *I burn*), in the higher Geometry, is the *caustic by refraction.* It is generated as follows:—If rays Pm issuing from a luminous point P be refracted by the curve A m B, so that the sines of incidence are to the sines of refraction in a given ratio, the curve C D H, which touches all the refracted rays, is called the *diacaustic.* or caustic by refraction. *See* CAUSTIC.



DIA'CHYLUM, or DIACHYLON. (Gr. δια, and χυλος, *juice.*) A celebrated plaister of former days made of the juices of several plants; the term is still retained, and applied to common plaister, made by boiling hydrated oxide of lead with olive oil.

DIACO'DIUM. (Gr. δια, and κωδια, *a poppy.*) A preparation of the poppy. Syrup of white poppies was formerly called *syrup of diacodium.*

DIA'COPE. (Gr. δια, and κοπτω, *I cut.*) A genus of spiny-finned fishes of the perch tribe, allied to *Serranus;* but distinguished by a notch at the lower part of the preoperculum, to which a projecting tubercle is adapted.

DIACOU'STICS. (Gr. δια, and ακουω, *I hear.*) That branch of physics which treats of the properties of sound refracted in passing through media of different densities. *See* SOUND

DIACRI'TIC MARKS. (Gr. διακρινω, *I distinguish.*) In Palæography, marks used to distinguish letters between the forms of which much similarity exists. Thus *n* and *u* are distinguished in German running hand by the mark ◡ over the latter letter.

DIADE'LPHOUS. (Gr. δια, and δελφυς, *a womb.*) A term applied to stamens the filaments of which have coalesced into two masses, as in Fumaria and many leguminous plants.

DI'ADEM. (Gr. διάδημα, from δεω, *I bind.*) Originally a fillet wound round the temples, probably imported into Greek costume from the East. It was the symbol of royalty among various oriental nations. The diadem of Bacchus, from the representation in ancient statues, &c., was a broad band, which might be unfolded so as to form a veil. Constantine the Great was the first Roman emperor who used the diadem; after his time, it was set with rows of pearls or precious stones.

DIÆ'RESIS. (Gr. διαιρεω, *I divide.*) In Grammar, the resolution of a diphthong, or a contracted syllable, into two syllables: as, in Latin, auraï for auræ, &c.; and, in English, the resolution of the last syllable of participles by giving a sound to the final *e:* belovëd, cursëd. &c. *See* METAPLASM.

DIAGNO'SIS. (Gr. διαγιγνωσκω, *I distinguish.*) The art of distinguishing one disease from another. The characteristic symptoms of diseases, by which they are recognized, are termed their diagnostic symptoms.

DIA'GONAL. (Gr. δια, *through*, and γωνια, *angle.*) A straight line drawn through a figure, joining two opposite angles. The term is chiefly used in geometry, in speaking of four-sided figures; but it is also properly applied with reference to all polygons of which the number of sides is not less than four. Euclid uses the term *diameter* in the same sense; but modern geometers use *diameter* only when speaking of curve lines, and *diagonal* when speaking of angular figures.

DI'AGRAM. (Gr. διαγραμμα; from δια, through, and γραφω, *I write.*) The figure or scheme drawn for the illustration of a mathematical proposition, or the demonstration of any of its properties. It is also used in other branches of science, and in the fine arts, for the general purposes of illustration.

DI'AGRAPH. (Gr. δια, and γραφω, *I describe.*) A name given by the French artists to a recently invented instrument used in perspective. For a minute description of its properties we beg to refer the reader to the *Encyclopédie des Gens du Monde*, and to the paper of M. Gavard, the inventor, recently published at Paris.

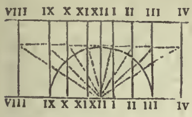
DI'AL, or SUN-DIAL. (Lat. dies, *day.*) An instrument for showing the hour of the day by means of the sun's shadow. The invention and use of sun-dials are of the highest antiquity. According to Herodotus, the Greeks learned the use of them from the Chaldeans; and the first of which history makes mention is the hemisphere of Berosus, who is supposed to have lived about 540 years before Christ. The sun-dial and the clepsydra were the only instruments known to the ancients for the measurement of time.

In constructing a sun-dial, the object is to find, by means of his shadow, the sun's distance at any time from the meridian. When this distance is known, the hour is also known, provided we suppose the sun's apparent motion to be uniform, and that during the whole course of a day he moves in a circle parallel to the equator. Neither of these conditions is, in fact, accurately fulfilled, but the error which this gives rise to is of small amount; and it is, moreover, sufficiently obvious that the use of a dial is not to indicate the hour with astronomical precision, but merely to give such an approximation as is necessary for the purposes of civil life.

Dials are usually constructed on an immoveable surface, and admit of an infinite number of different constructions, all depending on the nature of the surface and its position with regard to the equator of the earth. The general principles, however, are the same in all, and depend on the simplest elements of geometry and astronomy. The first part that claims attention is the *style* or *gnomon*, or axis of the dial, which is usually a cylindrical rod, or the edge of a thin plate of metal. The style must be directed perpendicularly to the terrestrial equator; in which direction it may be considered, on account of the smallness of the earth's diameter in comparison of the distance of the sun, as coinciding with the axis of the diurnal rotation; consequently the plane which passes through the style and its shadow on the surrounding surfaces, and which always passes through the centre of the sun, will be an hour plane, and turn with the sun as the sun turns round the style by the effect of the diurnal motion. All that remains to be done, in addition, is to discover, and describe, for the different hours of the day, the intersections of this variable hour plane with the surface on which the dial is to be constructed. On these intersections the shadow of the style will be projected every day at the same hour; because at the same hour the sun must have returned to the same hour-plane, although his distance from the equator may be different.

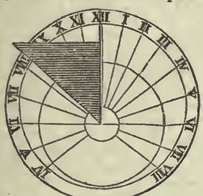
From these considerations it is manifest that the whole theory of dialling is comprehended in the solution of this general problem:—"Twelve planes all intersecting each other in the same straight line, and making with each other equal angles of 15°, being given in position; to find the intersections of those planes with any surface whatever, also given in form and position." The surface which intersects the hour planes may be of any kind whatever, but for obvious reasons it is generally a plane; and when its position with respect to the common intersection of the hour planes (which is the style of the dial) and to any one of those planes is given, the *traces* or intersections, which are in this case all straight lines, are the hour lines on the dial, and easily calculated by the ordinary rules of trigonometry or geometry.

According to the position of the plane of the dial with respect to the horizon of the place, the dial is *horizontal*, *vertical*, or *inclined*. The simplest case of all is that in which the plane of the dial is parallel to the axis of the earth (or passes through the poles) and perpendicular to the meridian of the place. In this case the style is also parallel to the plane of the dial, and the hour lines are parallel straight lines, whose distances from the meridian, or twelve hour line, are respectively proportional to the tangents of the angles which the hour planes make with the plane of the meridian.



Let d be the shortest distance of the style from the plane of the dial; then the distance of the hour line of XI and I from the hour line of XII is equal to $d \times \tan. 15^\circ$. The distance of the hour line of X and II from XII is $d \times \tan. 30^\circ$; the distance of IX and III is $d \times \tan. 45^\circ$; and so on, the hour line of XII being the intersection of the plane of the meridian in which the style is with the plane of the dial. This is called a *Polar Dial*.

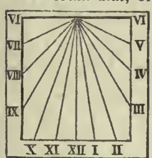
The most common construction is the *Horizontal Dial*, or that in which the plane of the dial is parallel to the horizon, and consequently makes with the style an angle equal to the latitude of the place. At the equator, this is the same as the polar dial, which has just been described; but at all other places, the hour lines intersect each other in the point in which the style intersects the plane of the dial, which point is called the centre, and the angles they make with one another, or with the XII hour line, depend on the latitude.



Their respective positions are computed from this theorem: — As is the radius to the sine of the latitude, so is the tangent of the hour from noon (reckoning 15° to the hour) to the tangent of the hour angle at the centre. Or, putting $h =$ the hour from noon, $l =$ latitude of the place, and $x =$ the hour angle at the centre of the dial; then the formula for computing the hour lines is $\tan. x = \tan. h \sin. l$, the radius being unit. From this formula the following table is computed, showing the angles which the different hour lines of a horizontal dial make with the meridional line, at the latitude of London, or $51\frac{1}{2}^\circ$.

MORNING.	AFTERNOON.		
XI	I.	11°	51′
X.	II.	24	19
IX.	III.	38	3
VIII.	IV.	53	35
VII.	V.	71	6
VI.	VI.	90	0

After the horizontal dials, the construction most frequently employed is that in which the plane of the dial is vertical; for example, when fixed on the wall of a house. In this case, the positions of the different hour lines depend on the latitude of the place and on the aspect of the dial; that is to say, its position with respect to the meridian. If the dial is perpendicular to the meridian, it is a *south dial*, or *north dial*, according as it faces the south or north. (The vertical south dial is represented in the annexed figure.) When not perpendicular to the meridian, the vertical dial is said to be *declined*. The formula for the hour lines of a south vertical dial differs from that for a horizontal dial in no respect excepting that the sine of the latitude is changed into the cosine, the cause of which will be obvious, when it is considered that the plane of the dial in passing from the horizontal to the south vertical direction preserves its inclination to the different hour planes unaltered; while the angle which it makes with the style, or the axis of the earth, is the complement of the angle it made with the same line in its former position.



Let y, therefore, be the hour angle at the centre of the dial; and putting, as before, $h =$ the hour from noon, and $l =$ the latitude, the formula for the south vertical dial is $\tan. y = \tan. h \cos. l$; whence it follows that a horizontal dial constructed for any given latitude will be a south vertical dial for any place of which the latitude is the complement of the latitude of the former place, — a property which was discovered by the Arabians. The hour lines of the vertical north dial are found exactly in the same way as those of the south dial.

When the face of the vertical dial is exactly east or exactly west, its plane is in the meridian, and consequently parallel to the vertical plane in which the style is. The hour lines, therefore, as in the polar dial, are all parallel to each other. Let d be the height of the style above the plane of the dial, h' the hour from 6 o'clock, and x the distance of that hour line from the hour line of VI, which is the intersection of the prime vertical with the plane of the dial; then $x = d \tan. h'$: the same formula as was given for the polar dial.

When the vertical dial does not face directly one of the four cardinal points, it is called a declining vertical dial, and the investigation of the hour lines is somewhat more complicated.

Let l denote the latitude of the place,
d the declination of the dial, reckoned from the east towards the south,
h the hour angle from noon,
y the hour line angle on the dial.

Find these two auxiliary quantities, viz. an angle P, and the tangent of an angle Q (of which only the logarithm is required), such that

$$\tan. P = \frac{\sin. l \tan. d}{\text{rad.}}; \quad \tan. Q = \frac{\cot. l \sin. P}{\sin. d};$$

then, the forenoon hours on the west declining dial, and the afternoon hours on the east, will be found from the formula

$$\tan. y = \frac{\tan. Q \sin. h}{\cos. (x + P)};$$

and the morning hours on the east declining dial, and the afternoon hours on the west, by the formula

$$\tan. y = \frac{\tan. Q \sin. h}{\cos. (x - P)}.$$

The formulæ which have now been given are sufficient to enable any one who has a slight knowledge of logarithmic computation to trace the hour lines of any one of the dials which has been described with great facility. It is therefore unnecessary to explain the *geometrical* methods of construction by the rule and compasses, which are besides less accurate, and more liable to be misunderstood. Of the mechanical operations necessary to be executed, such as fixing the style and placing the plane of the dial in the true vertical or horizontal position, it is unnecessary to speak, as they will readily suggest themselves to any one who has a clear conception of what is required to be done. The only thing that requires explanation is the method of finding the meridian line without having recourse to any of the more delicate operations of astronomy. The method generally practised is as follows: — Assume a point in the plane of the dial through which it is intended the meridian line shall pass. With this point as a centre, describe several concentric circles; then fix a pin or wire in the same point, perpendicular to the plane, and of such a length that the extremity of the shadow shall fall within the circles (or some of them) at midday. Observe the time when the extremity of the shadow reaches some one of the circles in the forenoon, and mark the point where it crosses the circle. In the afternoon mark the point where it again crosses the same circle, and divide the arc between the two points thus marked into two equal parts; the straight line which joins the point of bisection with the centre is the meridian line required. For greater security, the passage of the shadow over several circles may be marked; and if the points of bisection of the different arcs do not lie in the same straight line with the centre, a point must be chosen which occupies a mean position among all the others, and the straight line passing through it may be regarded as the true meridian. This method is sufficiently accurate for the purposes of a dial. Two plummets suspended over the meridian line will indicate the plane of the meridian in space. Its intersection with any vertical plane may be found by the eye.

It will be observed that the time indicated by a dial is *solar* time or *true* time, and agrees with *mean* time, or that which is shown by a well-regulated clock, only on four different days of the year. In order to find the mean time from the dial, it is necessary to apply a correction called the *Equation of Time*. (See the term.)

It has been supposed that the style is formed by a wire, or the straight edge of a thin plate; but a slit in a plate properly placed, allowing a line of light to pass, will evidently answer the purpose. Sometimes a small hole is preferred; and the hour lines, instead of being described on a plane surface, are sometimes described on the surface of a sphere, or a cylinder or a cone. The reader may find a description of some curious dials in Brewster's edition of *Ferguson's Lectures*. For the history of dialling, see *Delambre*, *Astronomie Ancienne*, tome ii.; *Montucla*, *Histoire des Mathematiques*, tome i. The writers on the subject are very numerous. For a concise and perspicuous treatise we may refer to the article in the *Encyclopedia Britannica*.

DI'ALECT. (Gr. διαλεκτος, from διὰ, signifying *division*, and λέγω, *I speak*.) In the philosophical sense of the word, any variety of a common language. Hence German, English, Swedish, &c. are all strictly said to be dialects, as coming all of them from the same original

stock. Commonly, however, we limit the application of the term dialect to the varieties of a national language; and speak of the dialects of English, French, &c. In Greek the four dialects (Doric, Ionic, Æolic, Attic) were the four written varieties of the language, each possessing a literature of its own. In this respect no modern tongue presents a parallel to the Greek; inasmuch as, in all, one dialect has been arbitrarily adopted as the standard of polite writing and conversation, and the written works which are extant in the other dialects are regarded merely as exceptions to the general rule.

DIALE'CTICS. (Gr. διαλέγομαι, *I converse or debate.*) This name was originally used by Plato as synonymous with metaphysics, or the highest philosophy. Strictly speaking, it can only be regarded as a preparatory discipline for such investigations, or at most as a scientific method of prosecuting them. The most splendid examples of dialectical subtilty that exist are to be found in the *Dialogues* of Plato, especially in those entitled *Parmenides, the Statesman and Sophist.* Aristotle expresses himself with some contempt of dialectics. It is certain, however, that its own logic owes its existence to the dialectical exercises of the Platonic schools; and that it may, in one point of view, be regarded as a body of canons and directions for their legitimate use. (*See* PLATONIC PHILOSOPHY.) In modern times various systems of dialectics have been propounded in different countries; but by no philosophers, either ancient or modern, has this science been more successfully cultivated than by the Germans, who, among a host of other names more or less distinguished, can boast of a Fichte, Kant, Leibnitz, Hegel, Schelling, and Schlegel, as the propounders each of a peculiar dialectical system.

DIA'LLAGE. (Gr. διαλλαγη, *difference.*) A mineral of a foliated structure easily divisible in *one* direction, its natural joints and fractures exhibiting a very *different* lustre and appearance.

DI'ALLING LINES, or SCALES. Graduated lines on rules or circles to facilitate the construction of dials. They usually consist of two lines of tangents and a line of latitudes. Such contrivances are of no great use; the readiest and best method is to compute the angles of the hour lines from the trigonometrical formulæ: when the angles are known, they can be set off by means of a scale of chords, or by any of the other methods employed in practical geometry.

DIA'LOGISM. (Gr. διαλογος, from δια, *through*, and λογος, *speech.*) In Rhetoric, a mode of writing which consists in the narration of a dialogue; *i.e.* in which the conversation of two or more persons is reported, without their being actually introduced as personages speaking; in which, therefore, the sentence is framed or governed by the third person instead of the first. A speech by a single person, or the species of conversation held by a person with himself (thinking aloud), when reduced into the narrative form, is also, although somewhat incorrectly, termed by French literary writers dialogism.

DI'ALOGUE. (Gr. διάλογος.) In Literature, a composition or part of a composition in the form of a conversation between two or more persons. The dialogue was the form most generally adopted by the ancients for the conveyance of instruction, and was considered equally applicable to the most grave and philosophical, and to the most ludicrous and comical subjects. Thus it was adopted by Plato, Cicero, and Lucian, with equal success. Plato chose this form for the conveyance of his philosophical sentiments; because real conversation had been the mode by which his master, Socrates (who left no writing), gave instruction to the Athenians. In the *Dialogues* of Plato, Socrates is himself introduced as the chief interlocutor. Among modern writers the philosophical dialogue has been frequently employed for the same purpose, more especially by the French, to whose language and mode of thought it should seem to be peculiarly suited. Among other eminent persons of that country who have enriched its literature with this species of composition are, Fenelon; Paschal, in his *Provincial Letters;* Bouhours, in his *Entretiens d'Ariste et d'Eugène;* Fontenelle, in his *Dialogues of the Dead*, and *Plurality of Worlds;* Galiani, *Sur le Commerce des Grains*, &c. In England this method of composition has been less frequently practised; and, perhaps, with the exception of Berkeley and Hurd, has rarely succeeded in the hands of those who attempted it. Both the Germans and Italians have attempted to impart a knowledge of their different philosophical systems in this manner. Among the latter may be mentioned Machiavelli and Algarotti; and among the former Lessing, Mendelssohn, Schelling, and Herder; though the labours of none of these distinguished persons in this department of literature are so important as to require any particular notice in this place. It has long been a question of dispute as to the class of subjects for the discussion of which this mode of writing is chiefly adapted, and upon this point various opinions have been entertained. Upon this question it is not our intention to enter; but we cannot refrain from citing here the opinion of a gentleman as to its peculiar fitness for conveying philosophical instruction, whom few will venture to gainsay on such subjects. "There are some subjects," says Mr. Hume, "to which dialogue writing is peculiarly adapted, and where it is preferable to the direct and simple method of composition. Any point of doctrine which is so *obvious* that it scarcely admits of dispute, but at the same time so *important* that it cannot be too often inculcated, seems to require some such method of handling it; where the novelty of the manner may compensate the triteness of the subject, where the vivacity of conversation may enforce the precept, and where the variety of lights presented by various personages and characters may appear neither tedious nor redundant. Any question of philosophy, on the other hand, which is so *obscure* and *uncertain* that human reason can reach no fixed determination with regard to it, if it should be treated at all, seems to lead us naturally into the style of dialogue and conversation. Reasonable men may be allowed to differ where no one can reasonably be positive; opposite sentiments, even without any decision, afford an agreeable amusement; and if the subject be curious and interesting, the book carries us in a manner into company, and unites the two greatest and purest pleasures of human life, study and society."

The dramatic dialogue differs from the philosophical, inasmuch as its subject is one of action. The whole of modern dramas is dialogue, with the exception of occasional monologue or soliloquy. (For a learned account of the *dialogue*, see the *Encyclo. des Gens du Monde.*)

DIA'METER. (Gr. δια, *through*, and μετρον, *a measure.*) A straight line passing through the centre of a geometrical figure, as that of a circle, ellipse, or hyperbola. Many figures have diameters, though they have, properly speaking, no centres; in this case, the diameter is the straight line which bisects all the parallel chords. Some geometers extend this definition, and apply the term diameter to the curve lines which pass through the points of bisection of all the parallel chords of other curves. In this sense every curve has a diameter. In astronomy the *apparent diameters* of the celestial bodies are estimated by the number of seconds in the angles they subtend at the eye. The apparent diameter (which is measured by the micrometer), compared with the distance of the body, gives its *real* diameter; for the distance of the sun or a planet is to its real diameter, as radius to the sine of the angle subtended by the apparent diameter of the body.

DIAMETER. In Architecture, the measure across the lower part of the shaft of a column, which is usually divided into sixty parts, called minutes, and forms a scale for the measurement of all the parts of an order.

DI'AMOND. (A corruption of *adamant;* from Gr. α priv., and δαμαω, *I conquer*, from its extreme hardness and difficulty of fracture.) The most valuable of the precious stones. Diamonds were originally discovered in Bengal, and in the Island of Borneo. About the year 1720 they were found in Brazil. They always occur in a detached state in alluvial soil. The primitive crystalline form of the diamond is a regular octahedron, of which there are numerous modifications. Diamonds are found of all colours: those which are colourless, or which have some very decided tint, are most esteemed; the latter, however, are rare. Those which are slightly discoloured are the least valuable. The diamond is the hardest known substance, and can only be polished by its own dust or powder. The art of splitting or cutting and polishing this gem, though probably of remote antiquity in Asia, was first introduced into Europe in 1486 by Louis Berghem of Bruges, who accidentally discovered that by rubbing two diamonds together their surfaces might be abraded. They are cut chiefly into two forms, *rose* and *brilliant:* the latter have the finest effect, but require the sacrifice of a larger portion of the gem; so that the weight of an ordinary polished diamond often does not exceed half that of the rough gem. The largest known diamond is probably that mentioned by Tavernier, in possession of the great mogul: it was found in Golconda in 1550; is of the size of half a hen's egg, and said to weigh 900 carats. Among the crown jewels of Russia is a magnificent diamond, weighing 195 carats: it is of the size of a pigeon's egg, and was purloined from a brahminical idol by a French soldier; it passed through several hands, and was ultimately purchased by the Empress Catherine for the sum of 90,000*l.* and an annuity of 4000*l.* Perhaps the most perfect and beautiful diamond hitherto found is a brilliant brought from India by a gentleman of the name of Pitt, who sold it to the regent Duke of Orleans for the sum of 100,000*l.* It weighs about 136 carats, or 544 grains.

That the diamond is combustible, was first proved by the Florentine academicians in 1694, who found that when exposed to the heat of the sun concentrated in the focus of a large lens, it burned away with a blue lambent flame. The *products* of its combustion were first examined by Lavoisier in 1772, who showed that when it was burned in air or oxygen it produced carbonic acid: subsequent experiments have shown that nothing but carbonic acid is thus formed; and hence it is proved that the diamond is charcoal or carbon in a pure and crystalline form.

DIA'NA. In Mythology, the Latin name of the goddess known to the Greeks by the name of Artemis (Ἄρτεμις), the daughter of Jupiter and Latona, and sister of Apollo. She was the virgin goddess of the chase, and also presided over health. The sudden deaths of women were attributed to her darts, as those of men were to the arrows of Apollo. In later times she was confounded with various other goddesses, as Hecate, Lucina, Proserpina, and Luna. In the two last of these characters she was said to appear in the nether world and in heaven respectively, while on earth she assumed the character of Artemis; whence she was called the three-formed goddess. Her power and functions in these characters have been happily expressed in the couplet —

> Terret, lustrat, agit, Proserpina, Luna, Diana,
> Ima, suprema, feras, sceptro, fulgore, sagitta.

She was generally represented as a healthy active maiden in a huntress's dress, with a handsome but ungentle expression of countenance. The homage rendered to Diana was so extensive that the silversmith who remarked that she was worshipped in all Asia and the world, can scarcely be accused of exaggeration. A catalogue of the various places where temples were erected in her honour would comprise every city of note in the ancient world. Among others may be mentioned Ephesus, Abydos, Heraclea, Aulis, Eretria, Samos, Bubastus in Egypt, Delos (whence she was termed Delia), and Mount Aventine at Rome. But of all her temples, that at Ephesus was the most celebrated. It was erected at the joint expense of all the states of Asia; and according to the accounts of ancient authors, it must have surpassed in splendour all the structures of antiquity, and fully deserved to be regarded as one of the wonders of the world. A small statue of the goddess, or, as she was termed by her votaries, the "Great Diana of the Ephesians," which was commonly supposed to have been sent from heaven, was here enshrined and adorned with all that wealth and genius could contribute. The fate of this temple is well known. On the day that Alexander the Great was born, it was set on fire by Eratostratus (*Val. Max.* 8. 14.), from a morbid desire to transmit his name even with infamy to posterity. This edifice was afterwards rebuilt on a plan of similar magnificence; and it remained in full possession of its wealth and reputation till the year 260 A. D., when it was completely destroyed during an invasion of the Goths.

DIA'NA, TREE OF. A name given by the old chemists to the crystallized silver which is separated when mercury is put into a solution of nitrate of silver.

DIA'NDROUS. (Gr. δις, *double*, and ανηρ, *a man*.) A term applied to any plant having but two stamens.

DIAPA'SON. (Gr. δια, *through*, and πας, *all*.) In Music, an interval used by most authors to express the octave of the Greeks. By one of the boldest metaphors with which we are acquainted, Dryden has beautifully availed himself of this expression in the well-known stanza of his first Ode to St. Cecilia's Day: —

> From harmony, from heavenly harmony,
> This universal frame began;
> From harmony to harmony
> Through all the compass of the notes it ran,
> The diapason closing full in man.

For an account of the diapason in the organ pipes, see ORGAN.

DIAPE'NTE. (Gr. δια, and πεντε, *five*.) In Music, an ancient term signifying a fifth.

DI'APER. A woven linen ornamented with patterns, and used for towels and table linen; it sometimes resembles an inferior kind of damask. It is said to have been originally manufactured at Ypres in Flanders; whence the term d'Ypres, corrupted into diaper.

DIA'PHANOUS. (Gr. δια, and φαινω, *I shine*.) A term applied to bodies which permit the light to pass through their substances. It is the synonyme of translucent. A body which allows the forms of objects to be seen through it is transparent.

DIAPHO'NICS. (Gr. δια, and φωνη, *sound*.) The doctrine of refracted sound. *See* SOUND.

DIAPHORE'SIS. (Gr. διαφορεω, *I carry through*.) A perspiration; hence also *diaphoretics*, medicines which promote perspiration.

DI'APHRAGM. (Gr. δια, and φραττω, *I divide*.) This term is applied to the straight calcareous plate which divides the cavity of certain shells into two parts only; its more common signification relates to the muscular and tendinous partition which separates the chest from the abdomen in mammalia.

DI'APHRAGMATI'TIS. Inflammation of the diaphragm, or of its peritonæal coats. The treatment is the same as that of pleurisy and peritonitis.

DIARRHŒ'A. (Gr. διαῤῥεω, *I flow through*.) A purging or looseness of the bowels. There are several varieties of diarrhœa, depending upon different causes, and consequently requiring in many instances distinct modes of treatment. In general it is necessary first to remove offending and irritating matters from the bowels by means of aperients; rhubarb, from its astringent tendency, is the purgative usually employed; afterwards astringents with warm aromatics, and the occasional addition of some form of opium, are prescribed and continued till the inordinate laxity of the bowels is quelled. Where diarrhœa is connected, as it often is, with excess of acidity in the stomach, magnesia, chalk, or carbonated alkalis are united to the other remedies.

DIARTHRO'SIS. (Gr. *articulation*.) The moveable connection of bones.

DI'ARY. (Lat. diarium, literally *a daily allowance;* from dies, *a day*), signifies properly a note-book or register of daily occurrences, in which the writer has a principal share, or which have come under his own observation, or have happened in his own time. The term *diary* is equivalent to the French *journal*, the Italian *diario* and *giornale*, and the German *Tagebuch*.

DIASCHI'SMA. (Gr. διασχιζω, *I cleave*.) In Music, an interval consisting of two commas.

DI'ASPORE. A laminated mineral, composed of 80 alumina, 18 water, 3 oxide of iron. A small fragment decrepitates when heated, and is dispersed in numerous fragments; hence its name, from the Gr. διασπειρω, *I scatter*.

DI'ASTASE. (Gr. δια, and ιστημι, *I set*.) A peculiar substance generated during the germination of barley, wheat, &c., which tends to accelerate the formation of sugar during the fermentation of worts. It is precipitated from infusions of bruised malt by alcohol. It is the principle which by its reaction on starch tends to develop sugar in the processes of germination and malting.

DI'ASTEM. (Gr. διαστημα.) In Ancient Music, a simple interval as distinguished from a compound one; to which latter was given the name of a *system*.

DIASTE'MA. (Gr.) In Zoology, the vacant space occurring in the dental series by the absence of the canine or laniary teeth.

DIA'STOLE. (Gr. δια, and στελλω, *I stretch*.) The dilatation of the heart and arteries.

DI'ASTYLE. (Gr. δια, and στυλος, *a column*.) In Architecture, that mode of arranging columns in which the intercolumniation or space between the columns consists of three diameters, or according to some of four diameters.

DIATE'SSARON. (Gr. δια, and τεσσαρα, *four*.) In Ancient Music, the interval of a fourth.

DI'ATHE'RMAL, or DIATHERMANOUS. (Gr. δια, and θερμη, *warmth*.) A term applied to certain substances, such as transparent pieces of rock salt, &c., which suffer radiant heat to pass through them, much in the same way as transparent or *diaphanous* bodies allow of the passage of light.

DIA'THESIS. (Gr. διατιθημι, *I dispose*.) A particular state of constitution predisposing to certain diseases: such as inflammatory, nervous, and putrid diathesis; uric diathesis, in which there is excess of uric acid thrown off by the kidneys; gouty diathesis, &c.

DIA'TONI. (Gr. δια, and τονος, *an extension*.) In Ancient Architecture, the angle stones of a wall, which were wrought on two faces, and which, from stretching beyond the stones above and below them, made a good bond or tye to the work.

DIATO'NIC. (Gr. δια, and τονος, *a tone*.) In Music, a term denoting the natural scale of music, which proceeding by degrees includes both tones and semitones. It includes the intervals formed by the natural notes, as well as those produced in transposing the natural.

DIAZENE'TIC. (Gr. διαζευγνυμι, *I separate*.) In the Ancient Greek Music, a term applied to the tone disjoining two fourths, one on each side of it, and which joined to either made a fifth.

DIAZO'MA. (Gr. δια, *through*, and ζωμα, *a cincture*.) In Ancient Architecture, the landings or resting places which encircled the amphitheatre at different heights, like so many bands or cinctures; whence the name.

DI'BBLE. In Agr. and Hort., a cylindrical piece of wood from one to two inches in diameter, and from 1 ft. to 2 ft. in length, having a cross handle at one end, and brought to a conical point at the other, for the purpose of making holes in the ground to receive plants or seeds. Dibbles which are used for planting potatoes or beans are commonly from two to two and a half feet in length, with a peg inserted near the ground in order that the operator may press it in with his foot.

DIBO'THRIANS, *Dibothri*. (Gr. δις, *twice*, βοθριον, *a pit; two-pitted*.) The name of a division of tape-worms, including those *Bothriocephalans* which have not more than two pits or fossæ on the head.

DIBRA'NCHIATES, *Dibranchiata*. (Gr. δις, and βραγχια, *gills; two-gilled*.) The name of the order of Cephalopods which includes those with two gills, and which are also characterized by having three distinct hearts; an apparatus for secreting and emitting an inky fluid; cephalic arms, never exceeding ten in number, solid, and supporting acetabulæ; and in short all the chief characteristics which are usually ascribed to the entire class of Cephalopods. The same term (*Dibranches*) is applied

by Latreille to an order of the class *Cirripedia*, comprehending those species which are similarly characterized by having two gills.

DICASTE'RIUM. (Gr. δικη, *justice*.) In Ancient Architecture, the name of a tribunal or hall of justice in Athens.

DICE COAL. A species of coal easily splitting into cubical fragments.

DICERA'TES, *Dicerata*. (Gr. δις, *double*, and κερας, *horn; two-horned*.) A name applied by De Blainville to a family of the order *Paracephalophora Polybranchiata*, comprehending all such Gastropodous Mollusks as have two tentacles on the head. The term *Diceras* was previously applied by Lamarck to a fossil genus of Bivalves.

DICHO'TOMOUS, *Dichotomus*. (Gr. διχοτομος.) Signifies the division of an object by repeated bifurcation, so that the branches are always in pairs.

DICHO'TOMY. An artificial system, in which natural objects are arranged according to the above mode of division.

DI'CHROISM. (Gr. δις, *double*, and χρωμα, *colour*.) A term in Optics, used to designate a property possessed by several crystallized bodies of appearing under two distinct colours according to the direction in which light is transmitted through them. Thus the muriate of palladium appears of a deep red colour along the axis, and of a vivid green when viewed in a transverse direction. Sir D. Brewster states (*Optics*, *Cab. Cyclopedia*) that in examining this class of phenomena, he found them to depend on the absorption of light, being regulated by the inclination of the incident ray to the axis of double refraction, and on a difference of colour in the two pencils formed by double refraction.

DICO'LOPHUS. (Gr. διχα, *separately*, and λοφος, *a crest*.) The name of the genus of wading birds (*Grallatores*), including the *cariama*, which is characterized by a tuft of feathers projecting from the crown of the head in two directions.

DICOTYLE'DONS. (Gr. δις, *double*, and κοτυληδων, *a seed-leaf*.) One of the primary classes of the vegetable world, consisting of all those plants that have their embryo furnished with two cotyledons, or with a greater number arranged on the same plane. These plants are also called Exogens.

DICTA'TOR. In Ancient History, a Roman magistrate appointed on special occasions to supersede the consuls. The first dictator was elected some years after the expulsion of the kings, on the occasion of a war with the Latins, while a dangerous sedition was feared at home; but the period is very uncertain. Dictators were appointed also for mere ceremonial objects, as for holding comitia. But the purposes for which the dictator was appointed differed so materially at different times, and the opinions of later historians respecting the extent of his authority are so conflicting and unsatisfactory, that more obscurity still exists upon this subject than almost any other within the compass of Roman antiquities. According to Niebuhr, the object aimed at in the institution of the dictatorship was to evade the Valerian laws, and to re-establish the unlimited authority of the patricians over the plebeians; for the appeal to the commonalty granted by these laws was from the sentence of the consuls, and not from that of this new magistrate. But this unlimited power did not extend over the patricians. The form of their election was precisely similar to that of the kings, who were appointed by the senate, while their authority was confirmed by a decree of the curies. Originally the dictator continued in office only six months; but at a later period this salutary rule was neglected. Sylla and Julius Cæsar, the last dictators, were nominated perpetual dictators; the former in the year 81 B.C., the latter after the battle of Pharsalia. The title was subsequently offered to Augustus by the people, but declined; and it was never afterwards assumed by the Roman emperors. An officer called magister equitum, appointed sometimes by the dictator, sometimes by the senate, and sometimes by the people, was always in attendance on the dictator. (See *Niebuhr's Rom. History*, and *Ersch and Gruber's Encyclo.*)

DI'CTIONARY (Mod. Lat. dictionarium), either signifies a collection of words in one or more languages, with their peculiar significations, arranged in alphabetical order; or it may be applied in a more extended sense to any work which professes to communicate information on an entire subject, or an entire branch of a subject, under words or heads digested in order of the alphabet. Hence dictionaries may be said to be of two sorts, — of *words*, and of *facts* or *things*; in the former sense the term *dictionary* being equivalent to *lexicon*, in the latter to *encyclopædia*.

Dictionary of words. — The ancients have left us no monuments of this species of literature; and, with a few brilliant exceptions, all the attempts that took place at the early period of the Christian era, and during the middle ages, are comparatively incomplete. It was not till after the invention of printing, when a taste for the classic literature of antiquity became general, that some laborious men, in the view of elucidating the Greek and Roman authors, and of facilitating the investigations of others, undertook the task of compiling dictionaries. Under the head LEXICON will be found a succinct notice of the chief performances in this department of literature; and we shall here restrict ourselves to the remark, that the history of ancient, and, with a few modifications, of modern lexicography, presents the singular phenomenon, that it is only when the language of a country is on the decline, or at all events has attained such a degree of perfection as to be apparently unsusceptible of further improvement, that dictionaries begin to be compiled. "No one," says an able writer, "thinks of writing a dictionary till the language he intends to illustrate has become a study;" and this is seldom the case till the age of its purity and vigour has gone by, till the phraseology of its original authors has become in some degree obsolete, and the caprice or ignorance of later writers has diversified or corrupted the significations of words. In modern times the honour of possessing the best dictionaries belongs to Italy, France, and England. These are the *Vocabulario degli Academici della Crusca*, extended in the latest editions to 6 vols. fol.; the *Dictionnaire de l'Académie Française*, 2 vols. 4to., to which a supplementary volume has been recently added; and *Johnson's Dictionary*, 2 vols. fol. 1755; — works unrivalled in plan and execution, and which, notwithstanding the cavillings of certain philologists, will long remain standards in their respective languages. The Spaniards also possess a dictionary of considerable reputation, entitled *Diccionario de la Lengua Castellana, compuesto por la Real Academia Espanola*, 6 vols. fol. 1726; but the Germans, perhaps from the cause above adverted to, that the resources of their language have, as is universally admitted, not yet been adequately developed, do not possess any dictionary of acknowledged authority.

Dictionaries of facts or things are of two species; being either devoted to separate or single branches of science, art, or literature, or embracing the whole circle of the arts and sciences. Of the former, the *Historical and Critical Dictionary* of Bayle, and the *Dictionnaire de la Bible*, by Dom Calmet, may serve as specimens; and of the latter, the *Encyclopédie Française*, and the *Encyclopædia Britannica*. That the idea of comprising all the sciences in a single work was not unknown in antiquity is evident from the expression εγκυκλιος παιδεια, which was used to signify such a course of instruction as should embrace all the sciences. The earliest approximation to this species of literature is to be found in the work of Varro, *Rerum Hum. et Divin. Antiquitates*, of which nothing remains but the title; and in the *Historia Naturalis* of Pliny, who has embodied in that work all the results of his multifarious studies and vast erudition. But the term *Encyclopædia* is said to have been first applied to works of this description by some of the Arabian writers of the middle ages, and particularly by Alfarabius, whose general treatise on the sciences is still preserved under this designation. Towards the close of the 16th and the commencement of the 17th centuries, there appeared in Europe several similar treatises with the same title, of which the most celebrated was that of Alstedius, in 2 vols. fol.; but none of these productions can be properly termed dictionaries or encyclopædias, being merely collections of treatises resembling rather such works as *Kett's Elements of General Knowledge*, &c., than corresponding to the modern notion of an encyclopædia. The strongest resemblance to the works in question is presented by the *Lexicon Universale Historicum Sacrum et Profanum* of Hofmann, 1677, in 2 vols. fol., and followed in 1683 by a supplement of equal extent; the form of which, at least, has served for a model to nearly all succeeding dictionaries or encyclopædias. (*Penny Cyc.*) It might perhaps be preposterous to assert that Hofmann borrowed the notion of his *Lexicon* from Bacon's theory of the *Encyclopædian Tree*, as set forth in the *Novum Organon* (Leyden, 1650); but, as M. Guizot has observed, there can be little doubt that the great abundance of dictionaries and encyclopædias which the whole of Europe has since witnessed is in some degree owing to that eminent philosopher's *Classification Complete et Raisonnée* of human knowledge.

The subjoined list contains a selection of the most valuable productions in this department of literature which have appeared since that time, arranged according to the place and date of their publication.

Great Britain.

1. Lexicon Technicum, or Universal Dictionary of the Arts and Sciences, 2 vols. fol.; the first published 1704, the second in 1710. A supplementary vol. was afterwards added.
2. Chambers's Cyclopædia, 2 vols. fol. 1728. This work was extended in a 7th edit. to 4 vols. fol. 1778-85, by Dr. Rees, who afterwards re-edited the work in 45 vols. 4to. (See *infrà*.)
3. An Univ. History of Arts and Sciences, &c., by Dr. De Coetlogon, 2 vols. fol. 1745.

4. Barrow's New and Universal Dictionary of Arts and Sciences, 1 vol. fol. 1751; with a suppl. vol. 1754.
5. A New and Complete Dict. of Arts and Sciences, by a Society of Gentlemen (commonly called Owen's Dictionary, from the name of the publisher), 4 vols. 8vo. 1754.
6. The Complete Dict. of Arts and Sciences, 3 vols. fol. 1766, by the Rev. Ben. Croker, Dr. Thos. Williams, and Sam. Clark.
7. Encyclopædia Britannica, 3 vols. 4to. 1771. The fifth edition of this work, completed in 1814, was extended to 20 vols.; and a supplement in 6 vols., under the editorship of Mr. Napier, added in 1824. A seventh edition of this work, in which the supplement is incorporated, is now in course of publication under the same editor; and will be completed during the present year.
8. The English Encyclopædia, 10 vols. 4to. 1795-1803.
9. The Cyclopædia, commonly known by the name of Rees's Cyclopædia, 1802-19. 45 vols. 4to.
10. British Encyclopædia, 6 vols. 8vo. 1807-9.
11. Encyclopædia Londinensis, 24 vols. 4to. 1810-29, by John Wilkes.
12. Brewster's Edin. Encyclop. 18 vols. 4to. 1810-30.
13. Pantalogia, or New Dict. of Arts and Sciences, 12 vols. 8vo. 1813-16. By Mason Good, Gregory, and Bosworth.
14. Burrowe's Modern Encyclopædia, 10 vols. 4to. 1816.
15. Encyclopædia Edinensis, 6 vols. 4to. 1816.
16. Encyclopædia Perthensis, 23 vols. roy. 8vo.; completed in 1816.
17. Encyclopædia Metropolitana, 1818. Not yet completed.
18. Oxford Encyclopædia, 6 vols. 4to. 1828; to which a supplement in 1 vol. was added in 1831.
19. The London Encyclopædia, 24 vols. 8vo. 1826.
20. Partington's British Cyclopædia, 10 vols. 8vo. 1833-36.
21. Penny Cyclopædia, large 8vo. 1833, now in course of publication.

France.

1. Dictionnaire Universel Français et Latin, known by the name Dictionnaire de Trévoux, 1704. 3 vols. fol. The fifth and last edition, Paris, 1771, was augmented to 8 vols. fol.
2. Encyclopédie, ou Dictionnaire raisonnée des Sciences, des Arts, et des Métiers, par Diderot et d'Alembert, 35 vols. fol. 1751-80. The original series consisted of 28 vols., of which 11 were plates. A supplement of 5 vols. was afterwards added, one of which consisted of plates; besides a "Table Analytique" of the whole work, compiled by M. Monchon, in 2 vols. A variety of encyclopædias of more or less reputation was published in France immediately after the "Encyclopédie" of Diderot and D'Alembert; but as they are all, to a greater or less extent, mere abridgments of, or compilations from, this great work, we do not think them worthy of notice in this catalogue.
3. Encyclopédie, ou Dictionnaire Universel raisonnée des Connaissances humaines, par le Professeur de Felici. Yverdun, 1770-75. 42 vols. 4to.; besides a sup. of 6 vols. 4to.
4. Encyclopédie Méthodique, &c., 1782, 1832, 201 vols. 4to., including 47 vols. of plates. In this work every art or science is treated of in a separate volume or series of volumes; so that it forms in fact a collection of dictionaries.
5. Dictionnaire des Sciences et des Arts, par Lumier, 3 vols. 8vo. 1805.
6. Encyclopédie Moderne, &c., par M. Courtin, 1823, &c. 24 vols. 8vo.
7. Encyclopédie des Dames, par une Société des Dames, Paris, 1821, &c.
8. Dictionnaire de la Conversation et de la Lecture. Paris, 1834-9. 52 vols. 8vo. or 104 livraisons.
9. Encyclopédie des Gens du Monde. Paris, 1833, &c. Of this valuable and popular work 30 parts or 15 vols. 8vo. have already appeared, bringing it down to letter I.

Germany.

1. Grosse vollständige Universal Lexicon, von Zedler, 1732-50, 64 vols. 8vo.; with a sup. Another edition was published 1751-54 in 4 vols. fol. Halle and Leipsig.
2. Deutsche Encyclopedie, &c., 1778-1804, by Koester and Roos. Of this work 23 vols. 4to. appeared, bringing it down to letter K.
3. Economische Encyclopedie, by Krunitz, Floerke, and Korte, 1774, 1828. 148 vols. 8vo. Berlin.
4. Conversations Lexicon, 1796-1809, 6 vols. 8vo.; besides a sup. of 2 vols. The 6th edition was completed at Leipsig, 1824, in 10 vols., with 2 of a sup.; since that time there have appeared several editions of this work materially augmented. An English translation of it, with the addition of much valuable information, was completed at Philadelphia, in 13 vols. 8vo. 1820-33, under the superintendence of Dr. Liebner; and a republication of this American work, with considerable improvements, has been recently completed at Glasgow, in 6 vols.
5. Allgemeine Encyclopedie der Wissenschaften und Künste, von Ersch und Gruber, 1818, &c. Leipsig. 65 vols. 4to. of this work have already appeared. It is divided into sections, of each of which A, H, and O are the commencement.
6. Gehler's Physicalisches Wörterbuch, neu bearbeitet von Brandes, Gmelin, Horner, Muncke, Pfaff. 9 vols. 8vo. Leipsig, 1825-40. As the title implies, it is confined to general physics, and physical astronomy; but its great value renders it worthy of a place in this catalogue.
7. Haus-Lexicon, or Vollständiges Handbuch praktischer Lebens-kentnisse für alle stände, 8 vols. 8vo. Leipsig, 1835-37.
8. Damen Conversations Lexicon, 10 vols. small 8vo. Adorf, 1835-38.

Besides these, there are no fewer than 19 Encyclopædias of greater or less extent in course of publication in Germany; but it has not been our fortune to see any of them, with the exception of the Conversations Lexicon der Gegenwart, which forms a species of supplement to the Conversations Lexicon above specified.

Italy.

1. Dizionario Scientifico ex Curiosa, Sacra, Profana, by G. P. Pinati. 10 vols. fol. Venice, 1746-51.
2. Encyclopedia Italiana. Naples, 1788.
3. Encyclopedia Methodica Critica Ragionnata delle belle Arti, by Pietro Zani. Parma, 1818-20.

But another branch of the same encyclopædian tree, which, as already remarked, yielded such brilliant fruits in the hands of Ducange, Bayle, and Calmet, has taken deep root in Europe, and more especially in this country, and has greatly contributed to the diffusion of knowledge; viz. the compilation of dictionaries appropriated to separate branches of literature, science, or art. A mere catalogue of these would swell this notice to a size wholly incompatible with our limits, as there is scarcely a department of human knowledge in which works of this class have not been published within the last fifty years. It is not our intention to enter upon a discussion of the positive or comparative merits of the works referred to, though there exist perhaps few more fertile fields for criticism; but, if we take into consideration the extreme difficulty of compiling a good dictionary, and the acquirements essential to the individual who undertakes it, we shall not be surprised if but a few only of the vast number of dictionaries with which the literature of this and other countries is inundated be respectably executed. It may be true that the qualities of brevity, precision, and distinctness, without which no work of this class is even tolerable, do not belong to the highest order of intellect; though they are, perhaps, quite as rarely to be met with as its more showy attributes; but it is easy to see that to give interest to a work of this nature, and to present the reader with satisfactory information in a perspicuous and compendious form, a more than ordinary share of ability is indispensable. Montesquieu said of Tacitus that he abridged all, because he knew all. But though a thorough knowledge of the subject be indispensable, that is not enough to enable an individual to make a good dictionary. He must be able to split it into its elements; to treat each part as if it were separate and independent, and the reader wished to study it only; and at the same time to preserve all the parts in due subordination to each other, and to the plan of the work. The judgment, tact, and variety of research and learning, to say nothing of the labour, necessary to give permanent interest and real value to a work of this sort in any of the great departments of human knowledge, may be more easily imagined than described; and hence the extreme fewness of such works. But even the inferior class of dictionaries have many recommendations; and though mostly compiled at second-hand from other works, and with but little unity of plan or execution, still, if they be *tolerably accurate and precise*, they cannot fail to be of great utility. We are aware, indeed, that this position has been denied; and that it has been contended that the general prevalence of dictionaries has exercised a baneful influence upon the literature of the age, inasmuch as, by making people satisfied with the information which they contain, they tend to generate a taste for superficial learning, and thus, by discouraging all reference to more elaborate treatises, strike at the root of original thought and profound erudition. Those, however, who adopt this line of argument, quite overlook the main objects which dictionaries are calculated to serve. Such arguments would have some weight had it been ever contemplated that the mathematician should study mathematics, the philosopher philosophy, the divine theology, or any professional man the subjects that form the basis of his profession, in a dictionary only. But this is by no means the case. The grand object aimed at in such works, is to place within the reach of persons engaged in the business of active life a mass of well-digested, accurate, and readily accessible information upon subjects not connected

with their own immediate pursuits, such as it might be exceedingly difficult for them to procure elsewhere; while even to the learned, or to those who have access and leisure to refer to more extensive depositories of human knowledge, they serve as convenient manuals or reference books. But upon this subject we cannot do better than transfer to our columns an eloquent passage from the elaborate paper of M. Guizot on *encyclopædias* (Paris, 1826), to which we beg to refer the reader for a clear and learned exposition of the merits of this species of literature. "Parlerai-je enfin de leur utilité commune et pratique, de l'abondante instruction, des innombrables enseignemens qu'elles fournissent, et qui s'appliquent à tant de circonstances, à tant de besoins de la vie? Dans les grandes villes, au milieu de toutes les facilités, de toutes les richesses de la société humaine, on oublie trop qu'une multitude de familles independantes, aisées, dont le travail n'absorbe point le temps ni les facultés, vivent dans une situation toute différente, celles-ci à la campagne, celles-lá dans de petites villes, éloignées de toutes ces ressources de la science et de l'industrie qui se pressent autour de nous. C'est là qu'on apprend à connaître le prix de cette science domestique qui se transporte en quelques volumes dans la solitude la plus profonde. Sans doute elle est incomplete et fautive; on se trompe souvent dans l'application qu'on en fait; mais, à tout prendre, elle éclaire et dirige plus souvent encore; elle diminue les embarras, les ennuis de l'isolement; elle rassure les imaginations; elle établit enfin, entre des milliers d'individus dispersés et les grands foyers de la science, une sorte de lien intellectuel dont l'importance et les effets se laissent difficilement apprecier." Such, then, being the purposes contemplated by works of this class, and such the acknowledged benefits that accrue from them, so far from the number and variety of works which have been published in the course of the last and present century under the title of dictionaries and encyclopædias, occasioning any surprise, we are almost warranted in anticipating that, owing to the gradual progress of human knowledge, the progressive augmentations to the stock of polite literature, and the number and rapidity of the inventions and discoveries which are constantly enriching the arts and sciences, this species of publication will continue to increase, and that, in a word, the literature of every country will gradually assume more and more of the dictionary form.

DI'CTUM. (Lat. *something said.*) A word used in common parlance to signify the arbitrament or award of a judge.

DI'CTYOTHE'TON. (Gr. *δικτυον, a net,* and *τιθημι, I place.*) In Ancient Architecture, masonry worked in courses like the meshes of a net. Also open lattice work for admitting light and air.

DIDA'CTIC (Gr. *διδασκω, I teach*), in the schools, signifies every species of writing, whether in verse or prose, whose object is to teach or explain the rules or principles of any art or science. Thus to this class of literature belong the writings of Aristotle on grammar, poetry, and rhetoric; Longinus's Treatise on the Sublime; and the *Institutiones* of Quintilian, &c. But the term has been borrowed from scholastic phraseology, and appropriated more exclusively to all poetical writings devoted to the communication of instruction on a particular subject, or of a reflective or ethical character, thence called *didactic poetry*. Were this the place for such investigations, it might be easily shown that the *didactic* must have been among the first species of poetical composition; and that the writings of the earliest poets of whom profane history makes mention, such as Orpheus and Linus, might with propriety be classed under this category. But be this as it may, this species of poetry has been in use from a very remote period, and there is scarcely any nation in which it has not taken root. Among the most celebrated poems of this species may be reckoned in ancient times that of Lucretius, *De Rerum Naturâ*, in which the Epicurean system of philosophy is explained; Virgil's *Georgics*, which has almost always served as a model to the didactic poets of succeeding ages; and Horace's *Art of Poetry;* and in more recent times, Pope's *Essays on Criticism* and *Man;* Du Fresnoy's *Art of Painting* (see Mason's translation in the Literary Works of Sir J. Reynolds); Vida and Boileau's *Art of Poetry;* Akenside's *Pleasures of the Imagination;* Armstrong's *Art of Preserving Health;* Somerville's *Chace;* Dyer's *Fleece;* Young's *Universal Passion,* &c. The reader will find in Blair's *Lectures*, vol. iii., a full exposition of the nature and characteristics of this species of poetry, and a critical notice of the most famed didactic poems of all ages and countries.

DIDA'CTYLE. (Gr. *δις, double,* and *δακτυλος, the finger; two-fingered, or two-toed.*) This epithet is applied to various animals, as to the ruminants among quadrupeds (by Klein), to the ostrich among birds; to the amphiuma, an amphibious reptile with two digits on each extremity; and to certain insects, as the *Pterophorus didactylus* and *Gryllotalpa didactyla.*

DIDASCA'LIA. (Gr.) A term in use among the Greek writers of antiquity, and till within the last century among almost all the nations of modern Europe, applied to the representation of dramatic pieces, or to critical notices of the stage, and of every thing appertaining thereto. The only paper with this designation, now in existence, is, as far as we know, that published at Frankfort, which enjoys a large circulation.

DI'DORON. (Gr. *διδωρον.*) In Ancient Architecture, a brick whose length was one foot, and its breadth one half its length.

DIDE'LPHYS. (Gr. *δις, double,* and *δελφυς, womb.*) A generic name originally applied to the opossum, and all other quadrupeds which like it have a duplicature of the integument of the abdomen forming a pouch, in which the prematurely born young are received, protected, and nourished, as in a second womb, until their growth is advanced to a stage corresponding to that of the new-born young in the ordinary mammalia. In modern systems the term is, singularly enough, restricted to that group of Marsupials in which there are certain species deficient in the abdominal pouch. The genus *Didelphys*, or true opossums, are characterized by the following dental formula — incisores $\frac{10}{8}$, canini $\frac{2}{2}$, molares spurii $\frac{6}{6}$, molares veri $\frac{8}{8}$, = 50; and by having the hinder foot provided with a thumb, and a prehensile tail.

DI'DUS. The generic name for the dodo or dronte. Birds of this kind were discovered by the Portuguese in 1499 on the island now called Mauritius, where they were afterwards observed by the Dutch in 1598, and in the early part of the following century. Original figures of the bird are given in *De Bry* (*Quinta pars Indiæ Orientalis, &c.*, MDCI.); by Clusius, in his *Exotica*, 1605; by Herbert, in his *Travels*, 1634; by Bontius (Piso's edition, 1658); and by Savery, in his celebrated picture of "Orpheus charming the Beasts," now in the museum at the Hague. The last figure is the best; it was painted, as were the other figures of exotic species in the same picture, from studies of the living animals preserved at that time in the celebrated menagerie of Prince Maurice of Nassau. It is highly probable that the same dodo was the subject of the painting of which the one now in the British Museum is a copy.

Besides this pictorial evidence there exist a head and a foot of the dodo in the Ashmolean Museum at Oxford, and a foot of the dodo in the British Museum. The following is Willoughby's translation of the original description of this extinct bird by Clusius: — "The dodo is called by Clusius *Gallus gallinaceus peregrinus*, by Nieremberg *Cygnus cucullatus*, by Bontius *Dronte*. This exotic bird, found by the Hollanders in the island called by the Portuguese *Cygnæa* or *Cerne*, that is the Swan Island, and Mauritius Island by the low Dutch, of thirty miles compass, famous especially for black ebony, did not exceed a swan in bigness; but was of a far different shape, for its head was great, covered as it were with a certain membrane resembling a hood; besides, its bill was not flat and broad, but thick and long, of a yellowish colour next the head, the point being black. The upper chap was hooked; the nether had a bluish spot in the middle, between the yellow and black part. They reported that it is covered with thin and short feathers, and wants wings, instead whereof it hath only four or five long black feathers; that the hinder part of the body is very fat and fleshy, wherein for the tail were four or five small curled feathers, twirled up together, of an ash colour. Its legs are thick rather than long, whose upper part, as far as the knee, is covered with black feathers; the lower part, together with the feet, of a yellowish colour; its feet divided into four toes, three (and those the longer) standing forward, the fourth and shortest backward, all furnished with black claws. After I had composed and writ down the history of this bird, with as much diligence and faithfulness as I could, I happened to see in the house of Peter Pauwius, primary professor of physic in the university of Leyden, a leg thereof cut off at the knee, lately brought over out of Mauritius his island. It was not very long from the knee to the bending of the foot, being but little more than four inches, but of a great thickness; so that it was almost four inches in compass, and covered with thick set scales; on the upper side broader, and of a yellowish colour; on the under (or back side of the leg) lesser and dusky. The upper side of the toes was also covered with broad scales, the under side wholly callous. The toes were short for so thick a leg; for the length of the greatest or middlemost toe to the nail did not much exceed two inches, that of the other toe next to it scarce came up to two inches; the back toe fell something short of an inch and a half; but the claws of all were thick, hard, black, less than an inch long; but that of the back toe longer than the rest, exceeding an inch. The mariners in their dialect give this bird the name *Walgh-vogel*, that is, a nauseous or yellow bird; partly because after long boiling the flesh became not tender, but continued hard and of difficult concoction (excepting the breast and gizzard, which they found to be of no bad relish), partly because they could get many

turtle-doves, which were much more delicate and pleasant to the palate. Wherefore it was no wonder that in comparison of those they despised this, and said they could be well content without it. Moreover they said that they found certain stones in its gizzard; and no wonder, for all other birds as well as these swallow stones to assist them in grinding their meat." Thus far Clusius.

Now, with respect to the parts of the bird which still remain to us, we infer that the head, from the sudden rising of the cranium above the face, and the form of the anterior extremity of the lower jaw, as also from the nostrils being covered with an arched scale, did not belong to a vulture or any other Accipitrine bird; while in the presence of the cere at the base, and the forward position of the nostrils, it resembles the rhea and apteryx among the Struthious birds. The apteryx, however, deviates more from the typical *Struthionidæ* in the shape of the bill and position of the nostrils than does the dodo. With respect to the foot in the British Museum, this differs from that of the vultures in the form and disposition of the tarsal scales, in the shortness of the middle toe, and the bluntness and straighter figure of the claws; while in all these respects it agrees with the foot of the apteryx and the Gallinaceous order. So that even those naturalists who, like Mr. Gray of the British Museum, still reject the evidence in proof of the Struthious nature of the dodo, and deny its existence at any period, are compelled to imagine that the bird represented in the original figures above quoted was made up by joining the head of a bird of prey to the legs of a Gallinaceous bird. The analogies of ornithology, however, by no means sanction the rejection of the multiplied, and, if we except Leguat's narrations, consistent evidence, of the actual existence of the Struthious dodo. Whoever inspects the painting by Savery, above mentioned (which seems hitherto to have escaped the attention of the naturalists who have written on the dodo), must feel a conviction that its original was no factitious or artificial specimen. Neither the head nor the feet still preserved in our museums can be referred to an albatross, a penguin, a vulture, or any other known existing species; while they closely correspond (allowing for the absence of the horny sheath of the bill) with the original figures of the dodo. We have therefore no hesitation in concluding that in other respects those figures are equally faithful representations of the extinct Struthious form in question. Such also appears to be the conclusion to which the learned writer of the article "Dodo" in the *Penny Cyclopedia* arrived; in whose words we shall conclude the present notice:—"If the picture in the British Museum and the cut in Bontius be faithful representations of a creature then living, to make such a bird a bird of prey, a vulture in the ordinary acceptation of the term, would be to set all the usual laws of adaptation at defiance. A vulture without wings! How was it to be fed? And not only without wings, but necessarily slow and heavy in progression on its clumsy feet. The *Vulturidæ* are, as we know, among the most active agents in removing the rapidly decomposing animal remains in tropical and intertropical climates; and they are provided with a prodigal development of wing to waft them speedily to the spot tainted by the corrupt incumbrance. But no such powers of wing would be required by a bird appointed to clear away the decaying and decomposing masses of luxuriant tropical vegetation—a kind of vulture for vegetable impurities, so to speak; and such an office would not be by any means inconsistent with comparative slowness of pedestrian motion."

DIDY'NAMOUS. (Gr. δις, *twice*, and δυναμις, *power*.) A term applied to flowers having four stamens, of which two are short and two are long.

DIE (Fr. dé), in Coinage, is the instrument by which the impressions are given upon the various denominations of coin. The following is an outline of the *die manufacture*, as conducted in her Majesty's mint:—The engraver selects a forged plug of the best cast steel of proper dimensions for his intended work; and having carefully annealed it, and turned its surfaces smooth in the lathe, proceeds to engrave upon it the intended device for the coin; the Queen's head, for instance. When this is perfect the letters are put in, and the circularity and size duly adjusted; it is then hardened, and is termed a *matrix*. Another plug of soft steel is now selected; and the matrix being carefully adjusted upon it, they are placed under a very powerful fly-press, and two or three blows so directed as to commence an impression of the matrix upon the plug; this is then annealed, and the operation repeated till the plug receives a perfect impression of the work upon the matrix. This impression is of course in *relief*, the original work upon the matrix being indented, and produces what is termed the *punch*. This, being duly shaped in the lathe, is hardened, and is employed in the production of impressions in soft steel or *dies*, which being properly turned and hardened, are exact *fac-similes* of the original matrix, and are used in the process of *coinage*. When a pair of dies are made of good steel duly hardened and tempered, and are carefully used, they will sometimes yield from two to three hundred thousand impressions before they become so far worn or injured as to require to be removed from the coining presses.

DI'ERESI'LIS. A term invented by Mirbel to denote a many-celled superior fruit; the cells being dry, indehiscent, few-seeded, and cohering by a common style round a common axis—Ex. *Malva*.

DIE'SIS. (Gr.) In Music, an interval less than a comma. The harmonical diesis is the difference between a greater and a less semitone.

DI'ET. (Lat. dies, *a day*; Germ. Reichstag.) A name given to the principal national assembly in many countries of modern Europe.

By the usage of the *German Empire*, two diets were summoned every year by the emperor, besides such as were convoked on extraordinary occasions. There were three chambers—1. That of the electors (*see* ELECTORS). 2. That of the sovereign princes, divided into two spiritual and four temporal benches. The counts of the empire voted collectively in four benches or divisions, and not as individuals; the prelates and the abbots in two. 3. The chamber of the imperial cities, divided into the Rhenish and the Swabian benches. The diets, together with the emperor, exercised the prerogatives of sovereignty. A decree of the diet was termed a recess of the empire. The diet of the modern Germanic Confederation is a meeting of plenipotentiaries, permanently assembled in the city of Frankfort-on-the-Maine. There are two diets: one termed *plenum*, in which the thirty-eight sovereign members of the confederacy have seventy votes divided between them; the other the lesser or ordinary, in which their votes amount together only to seventeen. In the latter assembly propositions are brought forward and discussed, which are decided in the other without discussion. On some fundamental questions unanimity is required, in order that any proposition may be adopted; in other cases a majority of two thirds is necessary. Austria presides in both diets, and has the casting voice in the lesser.

The diet of Hungary is composed of the king (Emperor of Austria) and the estates. The latter consist of the higher clergy, the magnates, the two courts of appeal, and two representatives from each chapter, county, city, and privileged district. They are divided into two chambers, called tabulæ.

The diet of Switzerland is composed of the representatives of the cantons, and manages such affairs as by the federal constitution are exempted from the jurisdiction of those several independent states. It is held every two years, alternately at Zurich, Berne, and Lucerne, which are termed the presiding cantons (vorort). The schultheiss or governor (chief executive magistrate) of the presiding canton is landamman of Switzerland for the time being. Each canton has one vote in the diet.

From a very remote period, down to 1832, Poland enjoyed a national assembly, or *diets*, which were of two sorts, *ordinary* and *extraordinary*. The ordinary diet was held every two years, and usually at Warsaw; though it was expressly enacted that every third meeting should be convened at Grodno, in Lithuania. The duration of its sitting was restricted to six weeks, and could not, under any pretext, be protracted beyond this period. The diet was composed of a selection from the nobility, who formed what was called the senate, and of the deputies returned by each of the palatinates and districts of the country. The number amounted to about 400. The period of its meeting was fixed by the king, who presided over its deliberations; except during an interregnum, when the business of summoning the diet devolved on the archbishop of Guesna. The *extraordinary* diets differed from the *ordinary* chiefly in this, that there was no stated period for the former being summoned together, that they were convoked only to listen to propositions from the throne, and lasted only four days.

As is well known, the throne of Poland was not hereditary, but elective; and, on the occasion of choosing the sovereign, the Polish diets were held in the open country, and were attended by all the nobility on horseback, armed and equipped as if for battle. On this subject the reader is referred to a work of great ability, by De la Birardière, entitled *Histoires des Dietes de Pologne, pour les Elections des Rois, depuis* 1572 *jusqu'en* 1674 (8vo. Paris, 1679). *Dietines* was the name given to the particular assemblies of the Polish nobility in which deputies were elected to serve in the ordinary diets, and to represent the wishes and interests of their constituents. In these dietines every gentleman possessing an estate of three acres had the right of voting, and every deputy was chosen by the majority of suffrages. (See *Dunham's History of Poland*.)

DIET DRINK. Alterative decoctions taken in considerable quantities; such as decoction of sarsaparilla, sassafras, dandelion, &c. *Lisbon diet drink* nearly resembles the compound decoction of sarsaparilla of the London Pharmacopœia.

DIETE'TICS. (Gr. διαιτᾳειν, *to nourish*.) That part of medical science which relates to the diet or ordinary food. *See* DIGESTION and FOOD.

DIEU ET MON DROIT. (Fr. *God and my right.*) The motto of the royal family of England. It was first assumed by Richard I., to intimate that he held his sovereignty from God alone, and not in vassalage to man; and it should seem that it fell into desuetude among the immediate successors of that prince, and remained so till the reign of Edward III., by whom it was revived when he first claimed the crown of France. Since that period, if we except the reigns of Elizabeth, William III., and Anne, the first and last of whom used the motto "Semper eadem," and the second, though only in his private capacity, "Je maintiendray," *Dieu et mon droit* has always formed the royal motto of England.

DI'FFERENCE. In Logic, one of the predicables. It is that particular quality which distinguishes the subject from all others, when contemplated from that point of view in which we are then regarding it; and is said, logically, to be part of the essence of the subject. The genus, together with the difference, is said logically to make up the species; the species, with the difference, to make up the lower species, or the individual: — *e.g.* To the genus metal add the difference "susceptible of magnetic attraction," and we obtain the species iron, which is distinguished from all other metals by the existence of that peculiarity. *See* LOGIC.

DI'FFERENCE, in Arithmetic and Algebra, is the excess of one quantity over another, or that which remains when one quantity is taken from another quantity of the same kind. In the higher mathematics the theory of *Finite Differences* forms an extensive branch of analysis, which is usually explained in treatises on the Differential and Integral Calculus. (See the treatises of Euler, Bossut, Lacroix, &c.; or the Appendix by Sir J. Herschel to the English translation of Lacroix's smaller work.)

DI'FFERENCES. In Heraldry, devices borne on the escutcheon to indicate the part of a family to which the bearer belongs. This has been effected by various methods, — at present by what are termed brisures, marks of filiation, or of cadency; being small charges placed conspicuously in the shield. The eldest son bears a label of three points; the second, a crescent; the third, a mullet; the fourth, a martlet; the fifth, an annulet or small ring; the sixth, a fleur-de-lys; the seventh, a rose; the eighth, a cross moline; the ninth, a double quatrefoil. The family of the second son repeat these differences on their own paternal mark of filiation: — *e.g.* the second son's first son bears a crescent ensigned with a label, and so on of the rest. Females do not bear differences.

DIFFERE'NTIAL (diminutive of Difference), in the higher Mathematics, denotes a quantity infinitely small, or less than any assignable magnitude. *See* DIFFERENTIAL CALCULUS.

DIFFERE'NTIAL CALCULUS. The name by which one of the most important branches of the higher mathematics is usually designated.

In confining ourselves to a very general view of the subject, it may be said that the object of the differential calculus is to find the ratios of the differences of variable magnitudes, on the supposition that these differences become *infinitely small;* an hypothesis which gives rise to considerable abbreviations in the general calculation of differences. But it is here necesssary to attend to the particular signification in which the terms *infinite, infinitely small,* are used in the language of the calculus. Every magnitude which forms the subject of mathematical reasoning is susceptible of augmentation or of diminution without limit. We may therefore always conceive a quantity to become so great as to exceed any finite assignable quantity of the same nature as itself; or so small as to be less than any finite assignable quantity also of the same nature as itself: in the former case the quantity is said to be infinite; in the latter, infinitely small. In this sense it is obviously not necessary to attribute a real and physical existence to an infinitely great or infinitely small quantity: it is sufficient to imagine that if we attribute to any quantity which enters into a question a value as great or as small as we please, there always exists, beyond this limit, a quantity of the same kind still greater or still smaller, and which in this sense is infinitely great or infinitely small in comparison of any other finite quantity of the same kind. So that a finite magnitude may be regarded as nothing, or zero, in comparison of one infinitely great; and an infinitely small magnitude as nothing, or zero, in comparison of a finite magnitude.

The infinitely small quantities which come under consideration in the differential calculus are called *differentials.* The differential of a magnitude or variable function is expressed by writing the letter d before the magnitude or function: thus dx signifies the differential of the variable magnitude x, $d\,(xy)$ the differential of the product of the two variables x and y, and so on. Instead of using the letter d, the English mathematicians formerly indicated the *fluxion* of a quantity (which is equivalent to the differential) by placing a dot over it; thus $\dot{x}$ represented the fluxion of x, and $\overline{\dot{x}\,y}$ that of the product $x\,y$; but this notation was found in the progress of the calculus to be inconvenient, and has been disused by all the modern writers. The letter d was introduced by Leibnitz, and it has been adopted by all the Continental writers since the origin of the calculus as the symbol of differentiation.

The principles upon which the doctrine of infinitesimal quantities can be best established have been the subject of much dispute among mathematicians, and various methods of deducing the fundamental theorems have been proposed, of which the principal are — the *differential method* of Leibnitz, the Newtonian *method of fluxions*, Newton's *method of prime and ultimate ratios* followed in the *Principia*, D'Alembert's *method of limits*, Lagrange's *method of derivation*, and Landen's *residual analysis*. The principles and general procedure of Leibnitz's method (which, properly speaking, is the differential calculus) may be explained as follows: —

The differential of a variable quantity may be defined to be the infinitely small difference between two successive states of the same variable, and the object of the calculus is to find this differential for all possible cases; that is to say, for all the possible functions of the proposed variables, such as x, y, z, &c., of which the particular differentials are expressed by dx, dy, dz, &c. Before explaining how this is done, it is necessary to examine into the distinction that must be made between the operation by which an ordinary or finite difference is found, and that to which we must confine ourselves when the difference is infinitely small, or a differential. If we consider the proposed system or function in any two determinate states different from each other, the difference of the two values of the same quantity taken in the two states will be determinate, and consequently cannot be supposed as small as we please, so that no part of its expression can be omitted; but if the two states of the function approach indefinitely near each other, the difference of the two values of the same variable may be rendered as small as we please. It then becomes a differential, and is in fact nothing more than the ordinary difference simplified by the suppression of the quantities which in its expression may be regarded as infinitely small in comparison of the other quantities of which it is composed. Such is the general principle of differentiation. (Carnot, *Reflections sur la Métaphysique du Calcul Infinitésimal*, Paris, 1813.)

From this general principle it follows evidently that in order to differentiate a quantity, or any function whatever of a quantity, or of several combined quantities, which function we shall represent by $\varphi\,(x, y, z, \&c.)$, it is only necessary to consider it in its second state; that is to say, when x, y, z, &c. having become respectively $x + dx$, $y + dy$, $x + dz$, &c., the function itself becomes $\varphi\,(x + dx, y + dy, z + dz, \&c.)$; to subtract the primitive value of the function from its value thus increased, which will give for the finite difference of the proposed function

$$\varphi\,(x + dx, y + dy, z + dz, \&c.) - \varphi\,(x, y, z, \&c.);$$

and, lastly, to pass from this difference to the differential by neglecting those quantities which in the development are infinitely small in comparison of those to which they are to be added, or from which they are to be taken away. This general rule will be better understood by showing its application to some particular examples.

1. Let it be proposed to differentiate the sum $a + b + x + y$, composed of constant and variable quantities. According to the general formula, the constants a and b have no differential; and those of x and y are dx and dy respectively; therefore the differential of the proposed sum, that is, $d\,(a + b + x + y)$ is $a + b + (x + dx) + (y + dy) - (a + b + x + y)$, which becomes on reduction $dx + dy$. Hence, *the differential of any sum whatever of constants and variables is equal to the sum of the differentials of the variables alone.*

2. Let it be required to differentiate $x - y$. Here we have $d(x - y) = (x + dx) - (y + dy) - (x - y)$; or after reduction, $d\,(x - y) = dx - dy$; whence the differential of the difference of any two variables is equal to the difference of their differentials.

3. Let it be proposed to differentiate the product $x\,y$ By the formula we have $d\,(x\,y) = (x + dx)\,(y + dy) - x\,y = x\,dy + y\,dx + dx\,dy$; but it is necessary to remark that the last term $dx\,dy$ is infinitely small in comparison of each of the two others, as will be evident on dividing it by either of them, for the quotient is obviously an infinitely small quantity. The third term must therefore be neglected; whence the formula becomes $d\,(xy) = x\,dy + y\,dz$. In like manner $d\,(xyz) = xy\,dz + xz\,dy + yz\,dx$; and so on for the differential of the product of any number of variable quantities.

4. Let it be proposed to differentiate the fraction $\frac{x}{y}$. By the general formula the difference will be $\frac{x + dx}{y + dy} - \frac{x}{y}$; which being reduced to a common denominator, becomes $\frac{y\,dx - x\,dy}{y^2 - y\,dy}$; and on leaving out the quantity $y\,dy$, which is infinitely small in comparison of y^2 with which it is joined, we have $d\,\frac{x}{y} = \frac{y\,dx - x\,dy}{y^2}$

5. Let it be proposed to differentiate the function x^m. In this case the general formula gives $(x + d\,x)^m - x^m$. Expanding $(x + d\,x)^m$ by the binomial theorem, we get $(x^m + m\, x^{m-1}\, d\,x + \frac{1}{2}(m-1)\, x^{m-2}\, d\,x^2 + \&c.) - x^m$, or $m\, x^{m-1}\, d\,x + \frac{1}{2}(m-1)\, x^{m-2}\, d\,x^2 + \&c.$, for the difference. But $d\,x^2$ being infinitely small in comparison of $d\,x$, the term into which it enters as a factor (and all the succeeding ones which are multiplied by $d\,x^3$, $d\,x^4$, &c.) must be rejected. We have therefore simply, for the differential, $d\,x^m = m\, x^{m-1}\, d\,x$. It will easily be understood that m may be any quantity, whole or fractional, positive or negative.

6. Let it be proposed to differentiate the expression a^x, in which a is a constant quantity, and x a variable exponent. According to the general principle the differential is $a^{x + dx} - a^x$, or $a^x \cdot a^{dx} - a^x$, or $a^x(a^{dx} - 1)$. Assume $a = 1 + b$, and we shall have $a^{dx} = (1 + b)^{dx}$; whence by the binomial theorem,

$$a^{dx} = 1 + d\,x\,b + d\,x\,b^2\,\frac{d\,x - 1}{2} + d\,x\,b^3\,\frac{(d\,x-1)\,(d\,x-2)}{2\cdot 3}$$

+ &c.; and as the quantity $d\,x$, being infinitely small in comparison of the finite numbers 1, 2, 3, &c., must be rejected, the equation, on transposing the first term of the second member, becomes

$$a^{dx} - 1 = d\,x\,(b - \frac{b^2}{2} + \frac{b^3}{3} - \frac{b^4}{4} + \&c.)$$

Substituting this value of $a^{dx} - 1$ in the expression $a^x(a^{dx} - 1)$, and writing $a - 1$ instead of b, we have for the differential of the proposed function

$$d\,a^x = a^x\,d\,x\left((a-1) - \tfrac{1}{2}(a-1)^2 + \tfrac{1}{3}\,(a-1)^3 - \&c.\right)$$

Or, making the constant factor (which is the Napierean logarithm of the number a) = M,

$$d\,a^x = \mathrm{M}\,a^x\,d\,x.$$

7. Let the proposed function be log. y. Make $x = \log. y$; then $d\,x = d \log. y$; and by the general definition of a logarithm, we have always, whatever may be the value of a, the base of the system, $y = a^x$. Hence $d\,y = d\,a^x$; and substituting for $d\,a^x$ its value M $a^x\,d\,x$, given in the last paragraph, we have $d\,y = \mathrm{M}\,a^x\,d\,x$. Substituting, therefore, y for a^x, and $d \log. y$ for $d\,x$, we find ultimately

$$d \log. y = \frac{d\,y}{\mathrm{M}\,y}.$$

8. Let it be proposed to differentiate sin. x, x being an arc of a circle of which the radius is 1. By the general principle d sin. x = sin. $(x + d\,x)$ − sin. x; whence, by the common trigonometrical formula, d sin. x = sin. x cos. $d\,x$ + cos. x sin. $d\,x$ − sin. x. Now if we recollect that $d\,x$ is an infinitely small arc, it will be obvious that its cosine differs from unity only by an infinitely small quantity, which therefore must be rejected. The formula consequently becomes d sin. x = sin. x + cos. x sin. $d\,x$ − sin. x = cos. x sin. $d\,x$. Again, $d\,x$ being infinitely small, it differs from its sine only by an infinitely small quantity, which must therefore be rejected. Hence sin. $d\,x = d\,x$, and we have

$$d \sin. x = \cos. x\,d\,x.$$

By the same process of reasoning we find d cos. x = − sin. $x\,d\,x$, and d tan. $x = \dfrac{d\,x}{\cos.\,x^2}$. It is unnecessary to give more examples; the method of applying the general principle is obvious.

Hitherto we have considered the system of variable quantities in two successive states only; but it may be considered successively in two, three, four, or any number of consecutive states, all differing infinitely little from each other. This consideration gives rise to successive *orders* of differentials, derived from each other by a continued repetition of the same operation. By differentiating a function of any variable quantities we obtain a derivative function, in which the corresponding quantities differ infinitely little from their values in the original function. Another differentiation gives a second derivative function, and so on; so that we obtain as many successive orders of differentials as operations are performed. But it is to be remarked, that the infinitely small differences between the quantities in the first derivative system and the corresponding quantities in the original function, are not the same as the infinitely small differences between the quantities in the second derivative system and the corresponding quantities in the first; and those between the second and third systems are again different from those between the first and second. Hence it follows that these differentials are themselves variable, and consequently, like all other variable quantities, have their differentials. If therefore we retain the symbol d as the characteristic of the differential of any species of variable, the expression $d\,d\,x$ will denote the quantity by which $d\,x$ is augmented in passing from the first derivative state to the second, exactly in the same manner as $d\,x$ represents the increase of x in passing from the original to the first derivative state. In like manner $d\,d\,d\,x$ will express the augmentation which $d\,d\,x$ receives in passing from the second system to the third, and so on.

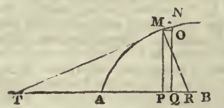
The quantities $d\,x$, $d\,d\,x$, $d\,d\,d\,x$, &c. are called the first, second, third, &c. differentials of x. In the same manner, $d\,y$, $d\,d\,y$, $d\,d\,d\,y$, &c. are the first, second, third, &c. differentials of y. Instead of writing $d\,d\,x$, $d\,d\,d\,x$, &c., it is usual to write $d^2\,x$, $d^3\,x$, &c. And this notation is not merely preferred on account of the abbreviation; it is absolutely necessary in many cases for the sake of carrying on the investigation when many successive differentials of the same variable are necessary to be considered. But these symbols must be carefully distinguished from $d\,x^2$, $d\,x^3$, &c., which are likewise abbreviations, but which at the same time denote real powers of $d\,x$, signifying respectively $d\,x\,d\,x$, $d\,x\,d\,x\,d\,x$, &c.; and they must also be distinguished from the quantities $d\,(x)^2$, $d\,(x)^3$, &c., which are the differentials of the powers x^2, x^3, &c. of x, while $d\,x^2$, $d\,x^3$, &c. are the powers of the differentials.

From these considerations it follows that the differentials of all orders are differentiated in the same manner as any other variable, and consequently no particular rules are required for this purpose. For example, the differential of $x\,y$ is $x\,d\,y + y\,d\,x$; and on differentiating this differential, we find $d\,x\,d\,y + x\,d^2\,y + d\,y\,d\,x + y\,d^2\,x$. Differentiating a third time, we get, on adding the similar terms, $3\,d\,x\,d^2 y + 3\,d\,y\,d^2\,x + x\,d^3\,y + y\,d^3\,x$, and so on.

In the application of the calculus, it is very important to observe, that when different variables are connected by equations we are always at liberty to assume the differential of one of the variables to be constant; and this constant differential then becomes a term of comparison, and serves to regulate all the others. For instance, in considering a curve line, we may suppose the successive infinitely small increments of the absciss to be all equal; in this case $d\,x$ is invariable, and consequently $d^2\,x = 0$. But the increments of the ordinate, which correspond to these equal increments of the absciss, are not equal, and consequently the differentials of $d\,y$ (or $d^2\,y$) are not zero; and the law according to which $d\,y$ varies in passing from one point to another, while $d\,x$ remains constant, is precisely that which will make known the nature of the curve. In other words, the nature of the curve will be determined by the relations between the successive differentials $d\,y$, $d^2\,y$, $d^3\,y$, &c. of the variable y.

Having now endeavoured to explain the general principles of the calculus, we shall give a few examples of its application to the theory of curve lines, the first subject to which it was applied by its inventors.

Let A M N be a curve line, which we may regard as a polygon of an infinite number of sides. Let one of these sides M N be produced till it meet the axis A B in T, and draw M P perpendicular to A B; then M T is the tangent and T P the subtangent. Through N, the other extremity of the side M N, draw N Q parallel to M P, and draw M O parallel to A B. Now, since M N is supposed to be infinitely small, M P and N Q are infinitely near each other; consequently M O is the differential of the axis A P = x, and N O the differential of the ordinate M P = y; whence M O = $d\,x$, and N O = $d\,y$. But the two triangles M N O and M T P are similar, therefore N O : O M : : M P : P T; that is, $d\,y : d\,x : : y :$ P T; whence P T = $y\,\dfrac{d\,x}{d\,y}$, an equation giving the value of the subtangent, and consequently the position of the tangent itself. It therefore only remains to determine the value of $y\,\dfrac{d\,x}{d\,y}$ from the equation of the curve. As an example, let it be required to find the subtangent of the commom parabola, the equation of which is $y^2 = a\,x$, a being the semiparameter of the axis. Differentiating the equation of the curve, we get $2\,y\,d\,y = a\,d\,x$; whence $\dfrac{d\,x}{d\,y} = \dfrac{2\,y}{a}$, and the subtangent $y\,\dfrac{d\,x}{d\,y} = \dfrac{2\,y^2}{a}$. Substitute in this expression $a\,x$ for y^2, and we have subtangent = $2\,x$, a well-known property of the parabola.



The position of the normal is found in a similar manner. Draw M R through M perpendicular to M T and meeting A P in R; then M R is the normal, and P R the subnormal. Because T M R is a right angle; therefore P R : P M : : P M : P T; that is, P R : $y : : y : y\,\dfrac{d\,x}{d\,y}$, consequently the subnormal P R = $y\,\dfrac{d\,y}{d\,x}$. Let the curve, for example, be an ellipse, the equation of which is $b^2\,x^2 + a^2\,y^2 = a^2\,b^2$, the co-ordinates being referred to the centre. The differential of this equation is $2\,b^2\,x\,d\,x + 2a^2\,y\,d\,y = 0$, whence we find $\dfrac{d\,y}{d\,x} = -\dfrac{b^2\,x}{a^2\,y}$; and consequently the subnormal $y\,\dfrac{d\,y}{d\,x} = -\dfrac{b^2}{a^2}\,x$.

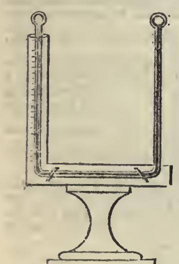
The differential calculus applies with like facility to the determination of the radii of curvature and the involutes of curve lines, to the finding of maxima and minima, in-

vestigations respecting series, and numerous other inquiries; in all of which it affords a singular facility in resolving questions, the solutions of which without its aid could only be obtained with great labour and difficulty.

The differential calculus was invented by Leibnitz; but reduced to a systematic form, and greatly extended, by the two celebrated brothers James and John Bernoulli. Some years, however, before Leibnitz fell on the discovery, the method of *fluxions*, with which the differential calculus agrees in every respect excepting its notation and the manner in which the principles are usually explained, had been invented and applied by Newton. This circumstance gave rise to a dispute, which was long carried on with great acrimony, between the mathematicians of England on the one hand, who put forward the claims of Newton for the honour of the invention, and those of France and Germany on the other, who gave the merit of it to Leibnitz. It was established beyond doubt that Newton was in possession of his method before it had been thought of by Leibnitz: the only question, therefore, was whether Leibnitz received such hints or information respecting the nature of Newton's method as were sufficient to guide him to its discovery. Of this there is no evidence, and extremely little probability; accordingly mathematicians have long agreed in recognizing the claim of Leibnitz to be regarded as an independent inventor. The notation introduced by Newton was followed generally by British mathematicians till some years after the beginning of the present century; but that of Leibnitz and the Bernoullis is now universally adopted.

DIFFERENTIAL COEFFICIENT, in Analysis, is the ratio of the differential of any function of a variable quantity to the differential of the variable. Let x and y denote two quantities related to each other by the equation $y = a x^2 + b x + c$, then y is a function of the variable x; the differential coefficient is $\frac{d y}{d x}$; and we have $\frac{d y}{d x} = 2 a x + b$. It is to be observed that the differential coefficient is not to be considered as an algebraic fraction, but merely a symbol, showing (in the present instance) that the function y has been differentiated with respect to x, and of which the two parts $d y$ and $d x$ have no independent meaning.

DIFFERENTIAL THERMOMETER. An ingenious instrument, of great use in experimental philosophy, for measuring very small differences of temperature; invented and first applied by Sir John Leslie, though the idea of an instrument of the same kind seems to have long before suggested itself to Sturmius. The differential thermometer is described by Leslie, in his *Experimental Inquiry into the Nature and Propagation of Heat*, nearly as follows: — Two glass tubes of unequal lengths, each terminating in a hollow ball, and having their bores somewhat widened at the other ends, a small portion of sulphuric acid tinged with carmine being introduced into the ball of the longer tube, are joined together by the flame of a blow-pipe, and afterwards bent into nearly the shape of the letter U; the one flexure being made just below the joining, where the small cavity facilitates the adjustment of the instrument, which, by a little dexterity, is performed by forcing with the heat of the hand a few minute globules of air from the one ball into the other. The balls are blown as equal as the eye can judge, and from four tenths to seven tenths of an inch in diameter.



To one of the legs of the thermometer a scale is attached; and the liquid contained in the tube is so disposed that it stands in the graduated leg opposite the zero of the scale, when both balls are exposed to the same temperature. From this construction of the instrument, it is easy to see that it is affected by the difference only of heat in the two balls. As long as both balls are of the same temperature, whatever this may be, the air contained in the one will have the same elasticity as that contained in the other; and consequently the intercluded coloured liquid, being thus pressed equally in opposite directions, must remain stationary. But if, for instance, the ball which holds a portion of the liquor be warmer than the other, the superior elasticity of the confined air will drive it forwards, and make it rise in the opposite branch above the zero, to an elevation proportional to the excess of elasticity or of heat. Sulphuric acid is chosen as the liquor best adapted to the purpose; because it is not vaporizable, and consequently does not by its vapour affect the pressure of the air above it. The carmine is used to render it more easily visible.

DIFFRA'CTION. In Optics, a species of deviation or inflexion which the rays of light undergo in passing very near the extremities of any opaque body. This phenomenon was first observed by Grimaldi, who described the principal appearances with sufficient accuracy; but it was Newton who first attempted to explain its cause by the general properties of light. His experiments are detailed in the last book of his *Optics*. In order to exhibit the phenomena of refraction, let a beam of solar light, reflected horizontally, be admitted into a dark chamber through a small round hole, and received on the white horizontal wall. If the hole has a sensible diameter, the image of the sun thrown on the wall will suffer no sensible alteration of colour; but if we place in the axis of the beam of light, and at a distance of 5 or 6 feet from the hole through which it is admitted, a metallic plate, having a puncture made in it by the point of a very fine needle, and intercepting all other light than that which passes through the puncture, the appearance on the wall will no longer be a circular spot of white light only; it will be surrounded with several concentric coloured rings, covering a space far exceeding in extent that which the solar beam would have occupied if the rays of which it was composed had followed their rectilinear direction. It is obvious therefore, both from the colours and the space occupied by the light, that the different rays have been reflected or bent in different degrees, and in a manner quite analogous to what takes place when light passes through a glass prism. By substituting a very narrow slit for the puncture in the metallic plate, or several punctures or slits very close to each other, and arranged in a certain manner, some of the most beautiful phenomena of optics are exhibited. The phenomena of diffraction have been much studied of late years, as affording a test by which to try the truth of the rival theories of light. At present the result is in favour of the theory of undulation, inasmuch as it has afforded a satisfactory explanation of all the phenomena without exception. *See* LIGHT.

DIFFU'SION OF GASES. When two gaseous bodies which do not act chemically upon each other are mixed together in any relative proportions they gradually diffuse themselves through each other; so that after a sufficient time has elapsed for the purpose, whatever may have been their relative densities, they are found intimately blended: the heavier gas does not fall, nor does the lighter one float. Dalton, therefore, has appropriately represented gaseous bodies as acting as *vacua* to each other. Professor Graham's researches have lately thrown much new light upon this subject, and he has determined the laws of *gaseous diffusion* by a series of well conceived experimental inquiry. (See *Graham's Elements of Chemistry*, vol. i. p. 71.; and *Quarterly Journal of Science*, N.S., vol. v.)

DIGA'MMA. (Gr. δις, *double*, and γαμμα (Γ), so called from its representing two gammas, one set above another, thus, F.) The name given to the form of that letter in the ancient Greek alphabet which corresponds in appearance generally to the Latin F.

A mere outline of the controversies that have prevailed among the learned respecting the form and power of the digamma, the mode of its pronunciation, and the purposes which it served in the early language of Greece would occupy more space than our prescribed limits admit of; and we must content ourselves with referring the reader to the article "Digamma" in the *Encyc. Metrop.*, and Ersch and Gruber's *Allgem. Encyc.*, in which the discussions on this subject display great learning and research. This letter appears to have occupied the sixth place in the alphabet, and was most prevalent in the Æolic dialect; though some grammarians contend that it was common to all the dialects of Greece in their more ancient mode of pronunciation. It has often been expressed by B, and sometimes by, Γ, Δ, Θ, Φ, and X; and it is now almost universally considered to have had the force of F, V, or the English W. As the Latin language approximated more nearly to the Æolic than to any of the other Grecian dialects, the use of the digamma is very prevalent in many Latin words, and the facility with which it was there interchanged for V, both at the commencement and in the middle of words; will be at once apparent from the following examples: — Gr, εαρ, *spring*, Æol. Fεαρ, Lat. ver; Gr. ἑσπερος, *evening*, Æol. Fεσπερος, Lat. vesperus; Gr. οινος, *wine*, Æol. Fοινος, Lat. vinum; Gr. ωον, *an egg*, Æol. ωFον, Lat. ovum, &c. (See Kidd's edition of *Dawe's Miscellanea Critica*, pp. 175—335.; and *Buttmann's Greek Grammar*.)

DIGA'STRIC MUSCLE. (Gr. δις, and γαστηρ, *belly*.) A double muscle, situated externally between the lower jaw and mastoid process; it is attached to the *os hyoides* in the human subject at the middle of its course. It pulls the lower jaw downwards and backwards; and when the jaws are shut it draws the larynx, and with it the pharynx, upwards in the act of swallowing.

DI'GEST. Several compilations of the Roman Law have been so called; but the best known is that which was made by order of the emperor Justinian. It is also

termed the Pandects, from the Greek words παν, *all*, and δεχεσθαι, *to receive;* signifying the general nature of the collection. The care of this great compilation was entrusted by the emperor to Tribonian, with seventeen associates. It was completed in three years, and published A.D. 533. It contains the best decisions and opinions of former jurists, collected, it is said, from more than two thousand volumes; and follows the same arrangement as the code of the same emperor, which had appeared in 529. The Pandects of Justinian, according to the commonly received story, were neglected in the Eastern Empire shortly after the decease of that emperor, and were wholly lost in the West until the accidental discovery of a MS. at Amalfi in 1130. But this tradition is now generally believed to rest on no solid foundation. *See* LAW, CIVIL. (See also *Gibbon*, cap. 44.; *Savigny on the Roman Law.*)

DIGE'STER. A strong iron or copper vessel with a tightly adjusted lid, furnished with a safety valve, in which bodies may be subjected to the action of high-pressure steam.

DIGE'STION. The general process by which food is converted into *chyme* in the stomachs of animals, and by which it is rendered fit for the production of *chyle*, and ultimately of *blood*. The term digestion is also more generally applied to the entire functions of the intestinal canal. The phenomena of digestion, though exclusively chemical, are also under the immediate influence of vitality, and are consequently perfectly different from any changes which the food suffers out of the body; hence the unsatisfactory conclusions of the older physiologists, who considered attrition, fermentation, and similar mechanical and chemical processes as sufficient to account for the extraordinary changes that are produced. It has been clearly ascertained that the influence of the nervous system is essential to the due performance of the functions of the stomach; and that when the brain, or the nerves that supply that viscus, are either injured or divided, digestion is either impaired or altogether suspended, and the food then ferments and putrefies instead of digesting. It has been said that the transmission of a current of electricity through the nerves is equivalent to their connection with the brain, and that under such circumstances the stomach, notwithstanding the division of its nerves, continues its functions; but these, and other statements in which electricity is said to be equivalent to the nervous and cerebral agency, require much more extended experimental proofs than they have hitherto received, before they can be admitted as true interpretations.

DIGESTION. In Surgery, this term was formerly applied to the treatment by which wounds or ulcers were brought into that state in which they form healthy pus: the remedies or applications promoting this object were termed *digestives*.

DI'GGING. The operation of moving earth with a spade. In gardens where the soil is loose the main object of digging is to mix the soil by burying the surface and bringing what is below to the top, and in that case a spade with a large blade may be used; but in digging firm ground spades can only be used which have narrow blades, as these may be more easily made to penetrate the ground.

DI'GIT (Lat. digitus, *finger*), in Arithmetic, signifies one of the ten symbols, 0, 1, 2, 3, &c., by which all numbers are expressed. By astronomers the term is used in speaking of eclipses, to denote the twelfth part of the diameter of the sun or moon. Thus, the eclipse is said to be of ten digits, if ten parts out of twelve of the diameter are concealed. It is convenient to employ this mode of defining the magnitude of an eclipse.

DIGITA'LIA. A vegetable alcaloid, procured from the leaves of the digitalis. *See* FOXGLOVE.

DI'GITIGRADES, *Digitigrada*. (Lat. digitus, *a digit;* gradior, *I walk.*) The carnivorous quadrupeds, which walk on the extremities of their digits. An artificial group of *Carnivora* is so called in the system of Cuvier.

DI'GLYPH. (Gr. δις, *twice*, and γλυφω, *I carve.*) In Architecture, a projecting face with two panels sunk thereon.

DI'GNITARY, in the Canon Law, signified originally a person who held an ecclesiastical benefice or dignity, which gave him some pre-eminence above mere priests and canons. To this class exclusively belonged all bishops, deans, archdeacons, &c.; but it now includes all the prebendaries and canons of the church.

DIGRE'SSION (Lat. digredi, *to diverge*), signifies any details introduced into a work, which are either altogether foreign from the immediate subjects of which it treats, or not absolutely necessary to the progress or development of the story. It will at once be perceived from this definition that, as a general rule, digressions are to be carefully avoided, from their tendency to withdraw the attention of the reader from the chief points of the story or the question under discussion. There are, however, some departments of literature in which the use of digressions is not only admissible, but even advantageous. On this subject, however, no definite rules can be laid down for the guidance of the author; but there can be little doubt that if introduced properly and without effort, managed with good taste, and confined within reasonable limits, digressions have the effect of relieving the mind from the fatigue of a too long sustained attention, and of imparting life and interest to a subject that may be naturally dry and uninteresting. The Essays of Montaigne exhibit more clearly than any similar productions with which we are acquainted, the admirable uses to which digressions may be turned in the hands of a master. Many of the writings of Sterne, but more especially his *Tristram Shandy* (which contains an eulogium upon digressions), supply the happiest examples of their effects; and in our times *The Doctor, &c.*, of which five volumes have already been published, owes its principal attractions to the digressions with which the story is interlarded. *See* EPISODE.

DIGRESSION, in Astronomy, denotes the apparent distance of the inferior planets Mercury and Venus from the sun. Mercury is never seen at a greater distance than about 28° from the sun; this is called its *greatest digression:* but on account of the great eccentricity of the planet's orbit, the limit is subject to considerable variation. The greatest digression of Venus is about 47½°, and it admits of a variation only amounting to about 2° 48′ between its extreme values. When the digression of an inferior planet attains it maximum, the visual ray along which it is seen is a tangent to the orbit, and the planet appears for some days nearly stationary. The term *elongation* is also used to denote a planet's apparent distance from the sun; but *elongation* is applied indifferently to any planet, whereas *digression* is usually confined to the two inferior ones.

DILA'PIDATION, chiefly in Ecclesiastical Law, is where an incumbent of a benefice suffers the parsonage house or outhouses to fall down or be in decay for want of necessary repairs, or commits any wilful waste of the inheritance of the church. Proceedings against an incumbent for dilapidations must be in the spiritual court. Against his executors, the remedy is either by proceeding in that court, or the successor may have an action of debt or on the case for damages at common law.

DILATA'TION. *See* EXPANSION.

DILE'MMA. (Gr. δις, *twice*, and λῆμμα, *an assumption; a twofold assumption.*) In Logic, a species of argument in the form of a complex conditional syllogism. (*See* SYLLOGISM.) It has been divided by logical writers into — 1. The simple constructive dilemma, in which the major premiss contains several antecedents all with the same consequent; the minor premiss grants that some one of these antecedents is true; and the conclusion infers that the common consequent is true: *e.g.* If A is B, C is D; and if X is Y, C is D; but either A is B or X is Y, therefore C is D. 2. The complex constructive dilemma, in which the several antecedents have each a distinct consequent; and it being granted that one antecedent is true, it follows that one consequent is true: *e.g.* If A is B, C is D; and if X is Y, E is F; but either A is B or X is Y, therefore either C is D or E is F. 3. The destructive dilemma, properly so called, has several antecedents with each a different consequent; and by denying the consequents disjunctively (*i.e.* denying that one or the other consequent is true) in the minor premiss, we proceed in the conclusion to deny the truth of one or the other antecedent: *e.g.* If A is B, C is D; and if X is Y, E is F; but either C is not D or E is not F, therefore either A is not B or X is not Y. Every dilemma may be reduced into two or more simple conditional syllogisms.

In the ordinary sense of the word, a dilemma is an argument in which two or more propositions are pressed upon the mind in such a manner that by granting which we will we are compelled to infer the same conclusion. One of the most celebrated dilemmas is that of the philosopher Protogoras in reference to his pupil Euathlus; for an account of which we beg to refer the reader to the *Athenian Letters*, vol. i. p. 149.

DI'LETTA'NTE. (It.) A term wholly naturalized in France, England, and Germany; signifying an amateur, chiefly of music, but also of the kindred sciences. There has existed in England, since the year 1760, a society called the *Dilettanti Society*, which was originally instituted by gentlemen who had travelled in Italy, simply for social purposes, and for perpetuating in each other's company the pleasure they had derived from their residence in that classic country: but its objects soon become materially extended; and it has acquired universal celebrity by the liberality with which it has devoted its funds to the purposes of science and art. The society still exists, and meetings of it are occasionally held. Some of the most famous travellers in Greece and Asia Minor, among whom we may mention Chandler, have been sent out at the sole expense of the Dilettanti Society; and many works illustrative of the art and science of the classic regions of antiquity, which would otherwise in all probability never have seen the light, have under their auspices been given to the world.

DI'LIGENCE. In Scottish Law, a general term, comprehending the process of law by which persons, lands, or effects are seized in execution or in security for debt

It is divided into that against the *heritage*, that against the *moveables*, and that against the person of the debtor; of each of which there are several species. (*See* INHIBITION, ADJUDICATION, POINDING, SEQUESTRATION, HORNING.) Diligence is also the name of the warrants issued by courts for enforcing the attendance of witnesses, or the production of writings.

DILLENIA'CEÆ. (Dillenia, one of the genera.) In Botany, a natural order of chiefly arborescent Exogens inhabiting the hotter parts of the world. Allied to *Magnoliaceæ;* from which they are distinguished by their want of stipules, and the quinary arrangement of the parts of fructification. They differ from *Ranunculaceæ*, to which they are also akin, in their persistent calyx and habit, and are universally characterized by the presence of an aril. Their properties are generally astringent.

DILL SEED. The seed of the *Anethum graveolens*, or *common dill*. This plant is grown for the supply of the medical market with seeds: they are warm aromatics, with something of the caraway flavour, and yield *dill water* and an essential oil when distilled with water. Dill water is a useful remedy in flatulency and gripes of children.

DI'LUENTS. (Lat. diluo, *I wash away.*) Water and aqueous drinks, which increase the secretion of urine and the perspiration, and appear to dilute the fluids of the body, are medically spoken of as *diluents*.

DILU'VIUM. (Lat.) The accumulations of gravel, &c. supposed to have been the consequence of the deluge.

DI'MERANS, *Dimera*. (Gr. δις, *two*, μηρος, *thigh.*) The name of a section of Coleopterans, comprehending those which have apparently only two joints in each tarsus; this structure, however, does not in point of fact exist, there being always a third rudimental tarsal joint.

DIMI'NISHED INTERVAL. In Music, one that is defective or short of its just quantity by a lesser semitone.

DIMINUE'NDO. (It.) In Music, an instruction to the performer to lessen the volume of sound from loud to soft, usually marked thus >.

DIMINU'TION. (Lat. diminutio.) In Music, a division of a large note into smaller ones; as a semibreve into two minims, four crotchets, &c.

DIMINU'TION. In Architecture, the gradual decrease of the diameter of a column as it rises. *See* ENTASIS.

DIMI'NUTIVE (Lat.), in Grammar, is applied to words which, by the addition of one or more syllables to those from which they are derived, soften the meaning or diminish the force and effect thereof. Every language is in a greater or less degree susceptible of diminutives; but in this respect, as is well known, the Italian language surpasses all those both of ancient and modern times.

DI'MITY. A cotton cloth of a thick texture, and generally striped or otherwise ornamented in the loom; it is chiefly used for articles of female dress, and for bed furniture or window curtains, and is very rarely dyed.

DIMYA'RIAS, *Dimyariæ*. (Gr. δις, *twice*, μυων, *a muscle.*) All those bivalves or conchifers are so called which have two distinct and separate adductor muscles, and consequently two corresponding muscular impressions on each valve.

DI'OCESE. (Gr. διοικησις, *a government.*) The territorial extent of a bishop's jurisdiction, embracing several parœciæ or parishes. As in early times the Christian converts were most numerous or most easily collected into a congregation in large towns, so in these towns did the bishop reside and minister to the faithful in his church, assisted by his priests and deacons. When the number of believers required the accommodation of additional temples, or congregations were formed in the neighbouring villages, the bishop was wont to appoint priests for their service, and the districts inhabited by these subsidiary congregations would become the parishes of his diocese.

DI'ODON. (Gr. δις, and οδους, *a tooth; two-toothed.*) The name of a genus of Plectognathic fishes with undivided jaws, each with a single and continuous dental plate.

DIONY'SIA. (Gr. τὰ Διονυσια.) In Ancient History, the festivals of Dionysus or Bacchus, but more particularly those that were celebrated in Attica, which were three in number, distinguished by the following titles:— 1. The Country Dionysia (τὰ κατ' ἄγρους). 2. Those in Limnæ (a part of the city of Athens, where they were held), which were also called Lenæan (τὰ ληναῖα, from λῆνος, *a wine-press*), or Anthesteria (Ανθεστήρια, from Anthesterion, the name of the Attic month corresponding to our January, in which they were celebrated); and 3. The Great Dionysia (τὰ μέγαλα). At all of these festivals the chief amusements consisted in the representation of stage plays; but the last was most celebrated, as then, before the face of all Greece, the great tragic contests were held, no expense being spared to render the decorations and accompaniments as splendid as art could make them: for on these exhibitions a great portion of the revenues drawn from the tributary states was expended, besides the private property of the persons appointed to superintend them, they being not only under the protection of the state, but a principal object of its care. (See *Bœckh's Public Economy of Athens.*)

DIOPHA'NTINE ANA'LYSIS. A branch of algebra, which treats of certain classes of indeterminate questions relating to square and cube numbers, rectangular triangles, &c. The name is derived from Diophantus, a mathematician of Alexandria, who is supposed to have lived in the third century of our era, and who examined and resolved a great number of questions of this nature in his celebrated treatise on arithmetic. Of this work, which exhibits the state of algebra among the Greeks, there are two editions: one by Bachet at Paris, in 1621; the other at Toulouse, in 1670, which is enriched by some valuable notes of Fermat. The following example will serve to illustrate the nature of the Diophantine problems; the object of which, in general, is to find commensurable numbers that satisfy conditions which may be satisfied by an infinity of indeterminate numbers. Suppose it were required to find three numbers, such that the sum of the squares of the two first is equal to the square of the third; that is, to find x, y, and z, such that $x^2 + y^2 = z^2$. The solution may be as follows:—Let $z = x + u$, then $z^2 = x^2 + 2xu + u^2$, and $x^2 + y^2 = x^2 + 2xu + u^2$, or $y^2 = 2xu + u^2$, whence $x = \frac{y^2 - u^2}{2u}$. Now we may choose for y and u any numbers we please, so that $y^2 - u^2$ is divisible by $2u$ (which will be the case if we make $u = 1$, and y any odd number whatever). For example, if we suppose $y = 3$, and $u = 1$, we have $x = 4$, and $z = x + u = 5$; so that the three numbers are 3, 4, and 5. Since $x^2 + y^2 = z^2$, it is obvious that x and y may represent the two sides of a right angled triangle, of which z is the hypothenuse. The student of the indeterminate analysis will find this subject very fully and perspicuously treated in the second volume of *Euler's Algebra*.

DIO'PSIS. (Gr. δια, *through*, and ωψ, *an eye.*) The name of a genus of Dipterous insects, remarkable for having the eyes and antennæ situated at the extremity of slender horny peduncles rising from the sides of the head, and equalling, in some species, the entire length of the body.

DIO'PTRICS. (Gr. διοπτρον, *something transparent;* from δια, *through*, and οπτομαι, *I see.*) A branch of Optics, of which the object is to investigate and explain the effects of the refraction of light when it passes through different media, as air, water, glass, &c. Its principal application is to the construction of telescopes and microscopes, and other instruments which require the use of refracting lenses. The term is not much used by modern writers on optics, the phenomena to which it refers being treated under the general head of *Refraction*. *See* LENS, LIGHT, OPTICS, REFRACTION.

DIORA'MA. (Gr. δια, *through*, and ὁραω, *I see.*) A mode of painting or scenic representation, invented by two French artists, Daguerre and Bouton, and recently brought forward as a public exhibition in all the principal cities of Europe.

The peculiar and very high degree of optical illusion produced by the diorama depends upon two principles; the mode of exhibiting the painting, and the manner of preparing it. With respect to the first of these, the spectator and the picture are placed in separate rooms, and the picture viewed through an aperture, the sides of which are continued towards the picture, so as to prevent any object in the picture room from being seen excepting the painting itself. Into the room in which the spectator is placed no light is admitted excepting what comes through this aperture from the picture; he is thus placed in comparative darkness, and also (which contributes to the effect) at a considerable distance from the picture. The picture room is illuminated from the roof, which is glazed with ground glass; and the picture so placed that the light falls on it at a proper angle to be reflected towards the aperture. The roof, which is invisible to the spectator, is provided with an apparatus of folds or shutters, by which the intensity of the illumination may be increased or diminished at pleasure, and so modified as to represent, with great effect and accuracy, the different *accidents* of light and shade, or the changes of appearance depending on the state of the atmosphere; as bright sunshine, cloudy weather, or the obscurity of twilight.

The second principle consists in painting certain parts of the picture in transparency, and admitting a stream of light upon it from behind, which, passing through the picture, produces a brilliancy far surpassing what could be obtained by illuminating the picture in the ordinary way, and renders the relief of the objects represented much stronger and more deceptive. Hence, the diorama is peculiarly adapted for representing architectural objects, as the interiors of cathedrals, &c.

In order to render the exhibition more attractive, it is usual to present more scenes than one. This may of course be effected by removing one picture and substituting another; but with a view to prevent the illusion from being impaired by the accidents incidental to scene-shifting, a different method is sometimes resorted to. In the diorama in the Regent's Park, the room in which the spectator is seated is a rotunda about 40 feet in diameter, which turns round a vertical axis by means of machinery placed under the floor. There are two pic-

ture rooms contiguous to each other, each containing a view; and when the scene is to be changed, the rotunda is turned round until the aperture in front of the spectators, which was first opposite to the opening into one of the picture rooms, is placed directly opposite the opening into the other. This contrivance, however, it will be observed, is independent of the principles peculiar to the diorama.

DIOSCOREA'CEÆ. (Dioscorea, one of the genera.) A natural order of Endogens, inhabiting the tropics, and agreeing with *Simlacea* by the genus *Tamus*, in having an inferior fruit; but differing from it by the threefold character of inferior ovary, capsular fruit, and the albumen having a large cavity. The mealy tubers of Dioscorea, under the name of *yams*, form an important food in all tropical countries.

DIP, in Magnetism, is the angle which a magnetic needle makes with the plane of the horizon, when poised on its centre of gravity and at liberty to turn in the vertical plane. *See* DIPPING NEEDLE.

DIP. In Geology, when strata are inclined, the angle which they make with the horizon is called the angle of *dip* or inclination, and the point of the compass towards which they slope is called the *dip of the strata*.

DIP OF THE SEA HORIZON. The apparent angular depression of the visible horizon, caused by the height of the spectator above the surface. To find it, multiply the square root of the height in feet by 1·063; the result is the dip in minutes (of a degree) and decimals. The actual dip observed is generally less than the true or abstract dip by $\frac{1}{14}$ on the average; but this is again affected by the temperature of the sea: when the sea is warmer than the air the horizon appears lower than its place by theory, and the contrary when the sea is the colder.

DI'PHTHONG (Gr. δις, *double;* and φθεγγομαι, *I sound*), has usually been defined to be a double vowel, or the union of two vowels pronounced together, so as only to make one syllable. If, however, this definition be more narrowly examined, it will be found to be deficient in two of the most essential qualities of a good definition — precision and accuracy. If, says Mr. Walker, a diphthong be two vowel sounds in succession, they must necessarily form two syllables, and therefore by the very definition cannot be a diphthong: if it be such a mixture of two vowels as to form but one simple sound, it is improperly called a diphthong; nor can any such simple mixture exist. Perhaps the best definition of a diphthong, although even that is far from embracing all the peculiarities of this class of letters, is to be found in *Smith's Scheme for a French and English Dictionary*, to which we beg to refer the reader.

DI'PHYANS, *Diphyes.* (Gr. δις, *two*, and φυη, *an offspring.*) A family of *Acelaphans*, comprehending those singular species in which two distinct individuals are always conjoined, one being lodged in the concavity of another.

DI'PLOE. (Gr. διπλοω, *I double.*) The horny or spongy substance between the tables of the skull.

DIPLO'MA. (Gr. διπλωμα, from διπλος, *double.*) Every sort of ancient charter, donation, bull, &c. is comprehended by writers on diplomatics under the name diploma. The term is derived from the earliest charters of donation with which we are acquainted, those of the early Roman emperors having been inscribed on two tablets of copper joined together so as to fold in the form of a book. Writings of earlier date than the fifth century are generally on leaves of the papyrus, or *Biblos Ægyptiaca;* those of a later period, on parchment. The form and character of the diploma granted by the sovereigns, prelates, nobles, &c. of modern Europe, varied from age to age; and the knowledge of these variations forms an important branch of the science of diplomatics.

DIPLO'MACY, in its most restricted sense, is used to express the art of conducting negotiations or arranging treaties between nations by means of their foreign ministers, or written correspondence; but, in its most extended signification, it embraces the whole science of negotiation with foreign states as founded on public law, positive engagements, or an enlightened view of the interests of each. But, upon this subject, we cannot do better than embody in our pages some remarks from the Introduction to Marten's *Manuel Diplomatique*, in which a distinct view is exhibited of the importance and main objects of diplomacy.

Diplomacy, says that able statesman, must be placed in the foremost rank of the useful sciences. The fate of nations, in the present state of the world, depends greatly on their relations with others; and these again are materially influenced and determined by the nature of their foreign policy, that is, by the success with which they have cultivated and applied the principles of this science. Diplomacy embraces —

1. The law of nations, by which the relations of one state with another are determined both in peace and war.
2. The political principles of individual states, as deduced from a regard to their peculiar interests; and a knowledge of the way in which these interests may be reconciled with, and made subservient to, the law of nations.
3. An acquaintance with the privileges and duties of diplomatic agents.
4. The conduct of negotiations, or the course to be pursued in treating of the interests of different states.
5. The moral and physical statistics of each power.
6. The political and military history of the states having diplomatic relations; and the projects, tendency, and policy of their respective governments.
7. The various systems of government, supremacy, concession, retention, equilibrium, centralization, confederacy, &c., that may be brought into operation.
8. The art of composing diplomatic despatches.

To this multifarious information the diplomatist should unite the powers of calculation and application peculiar to strong minds,—the "tact des convenances," which may be felt, but cannot be expressed, — circumspection, address, and perfect integrity. The combination of these various qualities will procure for the diplomatist such a character for sagacity, rectitude, and straightforwardness, as will sooner or later obtain for him an ascendency over the minds of others, and give great weight to his opinions.

It must be remembered that the diplomacy of every nation is more or less within the range of casualties; being subject to the versatility inseparable from human affairs, the fickleness and passions of man, and the uncertainty of events; — an unlooked-for death, a change of ministry, treacherous designs, undue influence from any quarter, a false calculation, corruption, — each of these causes may change the policy or course of a government; and this will more or less affect every other government, in proportion to the extent of its influence. In addition to these numerous causes of variation, if ambitious projects be entertained by any great power, diplomacy becomes still more intricate and difficult. Every state desires to be protected against the storm which its rulers imagine they can prognosticate, and of whose bursting they are apprehensive. Again, we must remark that the schemes of a government, how admirably soever contrived, have often miscarried, either from subordinate persons or those intrusted with putting them in execution having misapplied or misunderstood the instructions of their superiors.

From what has been said, it will be easily understood that, in diplomacy, false estimates are frequently formed of the merits of original plans or designs from looking at their results only. The diplomatist is of course exempted from all responsibility in regard to operations mixed up with the events of war; he is answerable only for the success of his projects under the conditions on which he proposed them.

A diplomatist of moderate capacity, if favoured by circumstances, may accomplish much more than the man of genius who has to contend with adverse fortune; but this difference of success makes no change in their relative ability, and those acquainted with the circumstances readily discriminate between sagacity and accident.

Diplomacy has been practised in substance ever since mankind have been formed into independent states, though it is difficult to ascertain the precise period at which the term came into use. The system, however, of the regular and uninterrupted residence of foreign ministers during peace at the European courts, as at present practised, is said to have originated with the Cardinal de Richelieu. Before that time embassies had been only sent on special occasions, but attended with much greater show and retinue than has been the fashion in modern times; while the substantial business of states at the neighbouring courts was transacted by agents of a lower stamp and character. Diplomatic agents are now ranked, in Europe, in the following order, according to the regulations of the Congress of Vienna: — 1. Ambassadors; 2. Envoys extraordinary and ministers plenipotentiary; 3. Ministers resident; 4. Chargés d'affaires; 5. Secretaries of legation and attachés: the latter, however, have no precise diplomatic character, and are only considered by courtesy as attached to the legation.

Among the best works on this important subject are the *Traité complet de Diplomatie, ou Theorie generale des Relations exterieures des Puissances de l'Europe*, par M. le Comte de Garden (Paris, 1833), 3 vols. 8vo.; and *De Wicquefort's Ambassadeur et ses Fonctions* (Ed. Opt.), 1746, 12 vols. 4to. See also the *Manuel Diplomatique*, by Von Marten (Paris, 1825); *Flassan's Hist. Gen. et Raisonn. de la Diplom. Française*, 7 vols. (Paris, 1811); and Von Marten's (senior) *Grundriss einer Diplom. Geschichte der Europ. Staatshandel, &c.* (Hamburg, 8vo).

DIPLOMA'TICS. The science of deciphering ancient writings, assigning their date, &c. The name is derived from *diploma*, which see. Writings of earlier date than the fifth century were mostly on the leaves of the papyrus, or *Biblos Ægyptiaca*. Parchment appears to have been first generally used in that century; and the oldest documents bearing the character of diplomas which we possess do not extend to a higher antiquity. Not long after the general adoption of parchment, a variety of substances and colours began to be used in

writing, as vermilion, purple, gold and silver; but this sumptuous fashion did not long remain in use. The science of diplomatics teaches the different styles and forms adopted in ancient public documents; the titles, rank, &c., of public officers whose names are subscribed to them; the knowledge of the materials used in writing in different ages, of the different characters used in successive periods and in various countries; and the several kinds of diplomas or public instruments.

This science is said to owe its origin to a Jesuit of Antwerp, named Papelroch, who devoted himself arduously to the research and exposition of old diplomas about the year 1675; but the honour of having reduced it to a science, and established it on a sure and more satisfactory foundation, is due to Mabillon, whose learned work, *De re Diplomatica*, was given to the world in 1681. The principles laid down by Mabillon, however, were more fully developed about the middle of last century, in one of the most elaborate works of which the literature of any nation can boast, the *Nouveau Traité de Diplomatique;* and which has left little to be done by subsequent labourers in this field beyond the duty of translation, compilation, or abridgment. From the above statement of the objects of this science, it will be at once perceived that it is of immense utility. It has greatly facilitated the researches of the historian, the politician, the divine, the political economist; and has contributed to the elucidation of points in the history of nations which might otherwise have been for ever buried in obscurity. We subjoin a list of the most important works on this interesting science, arranged according to the date of their publication; from which it will be seen that the French and Germans have prosecuted this science with an energy and enthusiasm to which, considering its vast importance, our national literature presents a most humiliating contrast. Besides the work of Papelroch above referred to, entitled the *Propylæum*, there are, Mabillon, *De re Diplomatica*, 6 vols. fol. (Paris, 1681), to which a supplementary vol. was added in 1704; *Historia Diplomatica*, by Maffei, 4to. (Mantua, 1727: this work may be regarded as merely a supplement to Mabillon); *Chron. Waltheri Lexicon Diplom.* 3 vols. fol. (Gotting. 1745-7); Heumann von Teutschenbrunn, *Commenta. de re Diplom. Regum, &c.*, 4to. (Nuremberg, 1745); *Nouveau Traité de Diplomatique*, by the Benedictine monks Toussaint and Tassin, 6 vols. 4to. (Paris, 1750-65.); *De Vaine's Diction. Raisonnée de Diplomatique*, 2 vols. 8vo. (Paris, 1774: this work is intended chiefly to aid beginners in the science); Gatterer, *Abriss der Diplomatik*, 8vo. (Götting. 1798); *Schœnemann's Prolusio de finibus Artis Diplom. Pract. Regundis;* and his *Versuch eines Vollständ. Systems der Allgem. besonders ältern Diplomatik*, 8vo. (Götting. 1802).

DIPLONEU'RANS, *Diploneura.* (Gr. διπλος, *double*, and νευρον, *nerve.*) A name applied by Rudolphi to that division of the animal kingdom comprehending the species which have two nervous systems, viz. the ganglionic or sympathetic, and the cerebro-spinal; the series so designated corresponds with the *Vertebrata* of Cuvier.

DIPLO'PIA. (Gr. διπλος, *double*, and οπτομαι, *I see.*) Double vision. This affection occasionally is symptomatic of nervous irritability, worms, indigestion, hysteria, &c.

DIPLO'PTERA. (Gr. διπλος, *double*, and πτερον, *a wing; doubled wing.*) The name of a division of Aculeate Hymenopterous insects, comprising those species of wasp which have the upper wings folded or doubled up longitudinally when at rest.

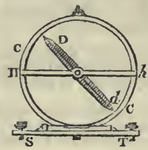
DIPLO'ZOON. (Gr. διπλος, *double*, ζωον, *an animal; double animal.*) The name of a very singular parasitic worm, which infests the gills of the bream, and which appears to be formed of two distinct bodies united in the middle, so as to present the appearance of a St. Andrew's cross, each half of the animal containing precisely the same organs; viz. an alimentary canal, a sanguiferous and a generative system.

DIPNEUMO'NEANS, *Dipneumoneæ.* (Gr. δις, *twice*, and πνευμων, *a lung; two-lunged.*) A term applied to a section of spiders (*Araneidæ*), including those which have only two pulmonary sacs.

DI'PPEL'S OIL. An empyreumatic oil, produced during the destructive distillation of bone.

DI'PPER. A name commonly given to the water-ouzel and other species of the genus *Cinclus.*

DI'PPING NE'EDLE. An instrument for showing the direction of the magnetic force of the earth. It is a magnetic needle, furnished with an axis at right angles to its length, and passing as exactly as possible through its centre of gravity, about which it moves in a vertical plane. When a needle thus mounted is placed any where not on the magnetic equator, it *dips*, or points downwards; and if the vertical plane in which it moves coincides with the magnetic meridian (which is always known by means of a variation compass), the position which it assumes shows at once the direction of the magnetic force; and the intersection of two or more directions, found by making the experiment at different places, indicates the place of the magnetic pole. Though the principles on which the dipping needle acts are abundantly simple, its practical construction is found to be exceedingly difficult. It must be accurately balanced on its axis; the axis must be placed exactly horizontal; the friction must be diminished to the utmost extent possible; and the adjustments can only be made when the needle is perfectly free from magnetism, and also secured from the effects of the magnetic influence of the earth. It must be subsequently magnetized, and during this process much care is required to guard against derangement. The simplest construction is represented in the annexed figure. The needle D *d* consists of a flat oblong piece of steel, tapering to a point at both ends, and having a slender cylindrical axis passed through its centre of gravity. The axis moves freely in circular holes made in the lateral horizontal bars H *h*, which support a vertical circle C C, graduated for the purpose of showing the inclination of the needle to the horizon. The stand S T, to which the circle is fixed, is provided with levels, and adjusted to horizontality by means of screws. But in the most improved form of construction of the dipping needle, the axis, instead of being a cylinder, is a knife edge, resting perpendicularly, like the supports of a pendulum, on two agate planes. A needle thus supported, however, must necessarily make small oscillations; consequently it must be so adjusted that when it points in the direction of the magnetic force, the knife edges may be perpendicular to the agate planes. The mean value of the angle of the dip must therefore be known previously to its construction; but it is the best adapted, on account of its delicacy, for ascertaining the minute variations of the dip at the same place. The angle of the dip, like that of the variation, changes its value even at the same place, following of course the motion of the magnetic poles, which, from the observations made by Scoresby, Parry, Ross, and others in high latitudes, appear to have a motion westward, the annual amount of which is about 11′ 4″. In the summer of 1831, Commander Ross, in an excursion from the vessel in which his party were so long detained in the polar seas, reached a spot on the continent of North America, which had been calculated to be the position of the magnetic pole. There he found the dip of the needle to be 89° 59′, within one minute of the vertical; and compass-needles suspended in the most delicate manner possible exhibited no polarity whatever. The latitude of this spot is 70° 5′ 17″ north, and its longitude 96° 46′ 45″ west. (For a description of some other forms of the dipping needle, see *Brewster's Treatise on Magnetism.*)



DIPSA'CEÆ. (Dipsacus, one of the genera.) In Botany, a natural order of herbaceous Exogens, chiefly inhabiting the south of Europe and a few other countries. Nearly allied to *Compositæ;* but differing in their stamens being distinct, and their ovule pendulous. They are distinguished from *Calyceraceæ* in the latter having connate anthers and alternate leaves; and from *Valerianaceæ* by their capitate flowers, and the presence of albumen. Their properties are unimportant. *Dipsacus fullonum* is employed mechanically, for the sake of its hard stiff bracts, in the process of dressing woollen cloths.

DI'PSAS. (Gr. *a viper.*) This term has been applied by Laurenti to a genus of Colubrine serpents; and by Dr. Leech to a genus of fresh-water Bivalves, intermediate to *Unio* and *Anodonta.*

DIPTERA'CEÆ. A natural order of arborescent Exogens, only found in India and the Indian Archipelago, very near to *Elæocarpeæ;* but distinguished by the petals not being fringed, and in the want of albumen. They are also allied to *Malvaceæ* in the contorted æstivation of the corolla and the crumpled cotyledons; but differ in the stamens being either distinct or partially combined, their long, narrow, 2-celled anthers, and pendulous ovules. Blume traces an affinity with *Guttiferæ* in their resinous juice, compound superior ovary, drupaceous fruit, numerous long anthers, irregular coloured calyx, and single exalbuminous seed; but from this order the stipules and the æstivation of the corolla abundantly distinguish them. The order is chiefly marked by the enlarged foliaceous unequal segments of the calyx investing the fruit. To it belongs the camphor tree (*Dryobalanops camphora*), which also yields the camphor oil of Borneo and Sumatra, and a timber called sal, the best and most extensively used in India; while other species yield pitch.

DI'PTERAL. (Gr. διπτερος, *double-winged.*) In Architecture, a temple which had a double range of columns on each of its flanks.

DI'PTERANS, *Diptera.* (Gr. διπτερος.) An order of insects having for their main and most conspicuous character two wings only corresponding to the anterior pair, and two short clubbed appendages, called *halteres* or balancers, and which seem to be the rudiments of the posterior pair in four-winged insects. The Dipterans are also distinguished by having the mouth in

the form of a sucker, composed of from two to six lancet-shaped elongated scales, inclosing a canal upon the upper surface of a fleshy tongue or proboscis. The larvæ or maggots of the Dipterous insects have frequently a membranous head; and always have the stigmata, or breathing pores, confined to the second and terminal segments of the body. In some species, as the blow-fly, the eggs are hatched within the body of the parent; in others, as the forest-fly (*Hippobosca*), the larva undergoes its metamorphosis in the parent's body, and the young are excluded in the form of *pupæ*.

DIPTERY'GIANS, *Dipterygia*. (Gr. δις, *twice*, and πτερυξ, *a fin; two-finned*.) A family of fishes comprehending those which have but two fins.

DI'PTYCH. (Gr. δίπτυχον, *twofold*.) Among the Romans, a tablet of wood, metal, or other substance, used for the purpose of writing, and folded like a book of two leaves: when the book consisted of several leaves, it was termed πολύπτυχον, or *manifold*. The diptychs of antiquity were employed especially for public registers. The sacred diptycha of the Greek church were double catalogues, containing on one side names of the living, on the other those of the dead, which were rehearsed during the office.

DI'PUS. (Gr. δις, and πους, *a foot*.) The general name for the Jerboas or Rodent animals, in which the hind-legs are disproportionately developed, and chiefly serve for locomotion. The numerous species referable to the Linnæan genus are now divided into the subgenera *Alactaga, Gerbillus, Dipus* proper, &c.; and form the family *Dipodidæ*: the *Gerbilli*, however, are more nearly allied to the *Muridæ*.

DIPY'RE. (Gr. δις, and πυρ, *fire*; i.e. a mineral doubly susceptible of the action of fire.) This mineral was originally confounded with *picnite*. It is found in the Western Pyrenees. When heated before the blowpipe, it first becomes phosphorescent, and then fuses: characters by which it is distinguished from picnite. It occurs in white or reddish white transparent or translucent crystals, of a prismatic form; its specific gravity is 2·63. It is hard enough to scratch glass. It is a silicate of alumina and lime.

DI'RECT. (Lat. dirigo.) In Music, a character used

at the end of a staff, to direct the performer's notice to the succeeding note at the beginning of the following staff.

DIRE'CTOR. A common surgical instrument: it is generally made of silver, and resembles a grooved probe. Its use is to direct the knife, and protect the parts underneath from its edge or point.

DIRECTORS. In Commerce, the name given to the individuals composing the board of management of a joint stock company; as the Bank of England, the E. I. Co., &c.

DIRE'CTORY. In French History, the name given by the constitution of 1795 to the executive body of the French republic. It consisted of five individuals, called directors, who were selected by the council of elders from a list of candidates presented by the council of five hundred. One of these directors retired every year, and was succeeded by another elected on the same principle. To the Directory was entrusted the superintendence of the home and foreign departments, the finances and the army, and the appointment of the ministers of state and other public functionaries. Its policy was at first moderate and conciliatory; but after a short interval it had recourse to measures which produced wide-spread dissatisfaction, and it was at length overthrown on the ascendency of Bonaparte after an existence of four years. (For the history of the Directory, see *Memoires de Gohier*, Paris, 1824.)

DIRECTORY, signifies also a book containing the names of the inhabitants of a town, arranged in alphabetical order, together with their places of abode, &c. It is likewise applied to a book containing directions for public worship, or other religious services.

DIRE'CTRIX. In Geometry, the name given to a certain straight line perpendicular to the axis of a conic section; and it is a property of these curves that the distance of any point of the curve from the directrix is to the distance of the same point from the focus in a constant ratio. The term is also sometimes applied generally to any line, whether straight or curved, which is required for the description of any curve.

DIRGE. (A contraction of *dirige*, used in the old formula of the Catholic service for the dead—*Dirige, Domine, Deus*.) A funeral song or hymn.

DISABI'LITY, in Law, signifies a state which renders a person incapable of enjoying certain legal benefits; as, the state of an alien renders him incapable of taking lands, that of infancy of making valid contracts, and so forth. Disability, it is said, may happen in four ways; by the act of the ancestor, of the person, of God, or of the law.

DISC, or DISK. (Lat. discus.) In Astronomy, the face of the sun, moon, or a planet, such as it appears to us projected on the sky. The forms of the celestial bodies being spherical, their projections are circular planes.

DISCHA'RGE. (Fr. discharger.) In Architecture, a term used to signify the relief or distribution of a weight or load to be borne; thus *discharging arches* are those used in any wall over a lintel to discharge the lintel of the weight which would be otherwise borne by it.

DISCI'PLE. (Lat. discipulus.) Literally, one who learns the principles of any science or liberal art from another; but the term is used in a eulogistic sense, more particularly to signify the followers of any renowned teacher or philosopher, whose spirit they have imbibed along with a knowledge of his peculiar tenets.

DI'SCIPLINE (Lat.), signifies, primarily, instruction or government; but it is applied figuratively to a peculiar mode of life, in accordance with the rules of some profession or society. It is also used to designate the punishments employed in convents, and those which enthusiasts undergo or inflict upon themselves by way of mortification.

DI'SCIPLINE, BOOK OF, in the Church of Scotland, is a common order, drawn up by the General Assembly in 1650 for the reformation and uniformity to be observed in the discipline and policy of the church. In this book episcopal government is set aside, Kirk sessions are established, the observance of saints' and other holy days is condemned, and other regulations for the internal government of the church are prescribed. It is called the First Book of Discipline.

DISCIPLINE, MILITARY. The obedience to and exercise of the laws of military men and matters: bravery may gain a battle, but the final event of war is essentially dependent upon discipline. "Discipline is the right arm of a general, and *money* is his shield."

DISCIPLINE OF THE SECRET, or DISCIPLI'NA ARCA'NI. A name given by theological writers to a system supposed to have been in force in the primitive church, by which its most important and mysterious doctrines were concealed from the mass of believers, and fully developed only to a select class. When at the beginning of the Reformation the Roman Catholics were urged with the silence or ambiguity of the fathers of the first four centuries upon many principal points of their doctrine, they met the objection by declaring it to be the constant custom of the primitive church, enjoined by the apostles themselves (for which they quoted 1 Cor. iii. 1, 2.), to throw a veil of mystery, or preserve entire silence, upon all such awful and incomprehensible subjects. The opinions of Protestants upon this question have certainly been far from uniform; but all allow probably that in the 4th century the practice alluded to was prevalent: the usage of the 3d is more equivocal, and there are few who attach any weight to the defence set up by their adversaries by appealing to the two first.

The following we are disposed to consider a fair representation of the subject.

The apostles and evangelists say very little directly and systematically concerning the principal doctrines of Christianity. We may suppose that in their private teaching they were more express, and that some particulars assumed a more definite shape from their connection with apostolic tradition, than would have been the case had they been derived to us from the language of the Holy Scriptures merely. But the comparatively private and temporary occasions of the writings of most of the apostles may account for this want of precision, without supposing that they purposely concealed their ultimate conclusions. The one or two passages upon which a contrary opinion is grounded certainly refer only to the spiritual progress of a believer, and not to any advance in the knowledge of forms and results. The writings of the Fathers of the first two centuries may, we believe, be pronounced entirely clear of any passage which can fairly be appealed to by the advocates of the Disciplina. In the third Clemens of Alexandria is considered to furnish the strong-hold of the theologians of that party; but although he makes a very marked and accurate distinction between the perfect and imperfect Christian, he founds it not upon superior knowledge of the doctrines, but upon an advance in purity and spiritual conduct. This is what he denominates true gnosticism, which he is at great pains to distinguish from the spurious and heretical; and even herein he appears to be speaking only from his own individual notions, or at least from those only of the Alexandrian school of theology, and not from any recognized opinions and usages of the church.

It is to be observed that the primitive church was wont to make some trial of the candidates for baptism, causing them to pass through a course of religious instruction, in which they were led by certain steps from the elemental to the more complete knowledge of their duties preparatory to that initiatory ceremony. This is no more than would be practised even now in the case of an adult convert; but such cases in these times are extremely rare, and hardly admit of a definite formal custom. But in the first four centuries the conversion of adults was the most prominent object of Christian solicitude: it was this that most drew the attention of the church; it was this therefore which naturally became the subject of formal ceremonics and practices. Accordingly in process of time, when the clergy began to feel the strength of their position, and to cherish the ambitious views which were prompted by it, this practice was an instrument fitted to their hands.

They made a mystery of that which was before only a second step in knowledge, and excited the awe or curiosity of their hearers by checking themselves ostentatiously when hovering on the borders of a doctrinal subject, with such phrases as ἴσασιν οἱ μεμυημένοι, *the initiated understand me*, &c.; and probably, by the rhetorical flourishes with which they screened their real meaning, deceived themselves, or at least posterity, into the exaggerated notions whose shape and system were finally confirmed at the Council of Trent.

DISCLAI'MER, in Law, is a plea containing an express denial or renunciation of some claim which has been made upon or by the party pleading. It is more especially taken for the denial, by an alleged tenant, of his tenancy. Such disclaimer is punishable at common law by the forfeiture of the land, if, on writ of right *sur disclaimer* brought, the lord succeed in proving the tenancy.

DI'SCOBOLES, *Discoboli*. (Gr. δίσκος, *a quoit;* βάλλω, *I throw*.) Those who played at quoits (*discus*) in antiquity. In Ichthyology, this word is applied to a family of pectoral or subbrachian fishes; comprehending those which have the ventral fins confluent, and forming a suctorious disc beneath the throat.

DI'SCOID. (Gr. δισκοειδής.) This term is applied to those univalve shells of which the whorls are disposed vertically on the same plane, so as to form a disc; as in the *pearly nautilus* and *planorbis*.

DISCONTI'NUANCE. In Law, an injury to real property, which consists in the keeping out the rightful owner of an estate by a tenant whose entry was at first lawful, but who wrongfully retains the possession afterwards: as, where tenant in tail makes a feoffment in fee-simple for life or in tail. In this case the heir in tail, remainder-man, or reversioner, is put to his writ: so alienations made by husbands seised in right of their wives, or by ecclesiastics seised in right of their church, work a species of discontinuance.

DI'SCORD. (Lat. discordia.) In Music, the relation of two sounds which the ear receives with displeasure, whether used in succession or consonance.

DISCO'RDIA. In Mythology, a malevolent deity, daughter of Night, and sister of Erinnys, the Parcæ, and Death. She is represented as having been banished from heaven by Jupiter, on account of the broils she perpetually occasioned. This was the goddess who, from disappointment at not being invited to the marriage of Thetis and Peleus, threw into the midst of the assembly the golden apple, with the inscription *detur pulchriori* (*let it be given to the fairest*); which, as is well known, occasioned the famed contest between the goddesses Juno, Minerva, and Venus, and ultimately led to the Trojan war, and the destruction of Troy. The ancient poets represent this divinity with a pale and ghastly look, a dagger in her hand, and her hair entwined with serpents; and Milton graphically describes her as

Discord, with a thousand various mouths.

DI'SCOUNT. An allowance made for the payment of money before it is due, and is equivalent to the interest of the principal sum diminished by the discount during the time that must elapse before the money becomes payable. The proper meaning of discount, and the rule for computing it, will be best understood from an example. Suppose the rate of interest to be 4 per cent., and that A holds a bill of 104*l.* payable a year hence. Suppose, also, that B has a sum of 100*l.* in hand, which he wishes to lay out at interest for one year. At the end of the year A's bill becomes due, and he receives 104*l.* B also receives back for principal and interest 104*l.* It is therefore clear that if at the commencement of the year A had given B his bill, and received from B his 100*l.*, neither party would have gained or lost by the transaction. Hence a bill of 104*l.*, payable a year hence, interest being 4 per cent., is equivalent to 100*l.* in hand; and the difference between the amount of the bill and its present value, viz. 4*l.*, is the discount. Now the discount on 104*l.* having been found, the discount on any other sum is found by simple proportion. If we observe that 4 is the rate per cent. of interest, and that 104*l.* is the present worth plus the discount, the truth of the following rule for the computation of discount will be apparent:—"As 100*l.* with the rate per cent. added is to the rate per cent., so is the principal sum to the discount." This rule supposes the time of payment to be one year; if it is less or more, the result must be diminished or increased in proportion to the time. Bankers and mercantile people, however, instead of computing discount in this correct way, reckon it in the same manner as simple interest, by which, in large transactions, they obtain a very considerable advantage. At 4 per cent. interest is 1 in 25, whereas discount is only 1 in 26.

DISCO'URSE. (Lat. discurrere, *to discuss*.) In Rhetoric, signifies in its widest acceptation a series of sentences and arguments arranged according to the rules of art, with the view of producing some impression on the mind or feelings of those to whom it is addressed. In Logic, this term is applied to the third operation of the mind, commonly called reasoning. *See* LOGIC.

DISCO'VERY. In Law, the act of revealing or disclosing any matter by a defendant in his answer to a bill in Chancery. *See* CHANCERY.

DISCRE'TE PROPO'RTION (Lat. discretus, *separated*), in Arithmetic, is a proportion in which the ratio of the antecedents to the consequents is different from the ratio of the consequent of the first pair of terms to the antecedent of the second. Thus, the proportion 2 : 3 : : 4 : 6, is a discrete proportion; for the ratio of 2 to 3, or of 4 to 6, is different from the ratio of 3 to 4. Discrete is therefore opposed to *continual*, a continual proportion being that in which the ratio of every two contiguous numbers is the same throughout; thus, 2 : 4 : : 8 : 16.

DISCRE'TE QUANTITY. A term applied to quantities of which the component parts have a separate and distinct existence. Thus, numbers are discrete quantities, being composed of separate units.

DI'SCUS. (Gr. δίσκος.) The ancient quoit, which consisted of a heavy circular mass of iron, sometimes perforated in the middle. In the ancient game, the players did not try to hit a mark, but to throw the quoit to the greatest possible distance. There is a discus preserved in the Cabinet of Antiques at Paris, in which holes are provided for the thumb and fingers. The practice of throwing discs is mentioned by Homer among the sports which occurred at the funeral of Patroclus; and Pindar celebrates Castor and Iolaus as skilful launchers of the discus.

DISCU'TIENT. (Lat. discutio, *I destroy*.) Remedies which repel or resolve tumours.

DI'SDIAPA'SON. (Gr. δὶς, *twice*, and διαπασῶν, *through all*.) In Music, two octaves or a fifteenth.

DISEA'SE. (Dis, and ease.) Any morbid state of the body generally, or of any particular organ or part of the body, is called a *disease*. By medical writers the term *disease* is defined as implying "a deviation from the natural and healthy actions of the whole system or of any individual part;" and they are in the habit of designating certain forms of disease by the following terms, namely: — *Acquired*, which are not congenital or hereditary, but derived from causes evidently operating after birth. *Acute*, which are severe, but of comparatively short duration. *Asthenic*, attended by manifest depression of the vital powers. *Chronic*, which are of long duration. *Congenital*, which are born with the individual. *Constitutional*, which more or less affect the whole system. *Contagious;* this term should be confined to those diseases only which are communicable from one to another by *contact*, either personal or intermediate: it is presumed, for instance, that the plague is a truly contagious disease, and that it can only be transferred from one individual to another by actual bodily contact, or through the medium of bedclothes or articles of apparel. The term "contagious disease" is, however, often misapplied to those which are *infectious*, or communicable through the medium of the atmosphere. *Endemic*, diseases which are either peculiar to particular places, or which are especially prevalent in certain districts only. *Epidemic*, diseases which are generally diffused over a whole country; they may generally be traced to atmospheric causes, and are commonly of an infectious character: influenza and cholera often prevail in this way. *Exanthematous* are those diseases which are accompanied by an eruptive fever, such as measles, small-pox, &c. *Hereditary* diseases are such as prevail in families, and are transmitted by parents to their offspring; gout and scrofula furnish examples. *Idiopathic* or *primary* diseases are those which are not dependent upon or symptomatic of others; certain affections of the head, for instance, may arise immediately from disease of the brain, or they may be mediately connected with disordered states of the stomach: the former are idiopathic, the latter *symptomatic*. *Intercurrent* diseases are those which arise in individuals from incidental causes during the prevalence of endemic or epidemic sickness. *Intermittent* diseases are marked by a regular cessation and recurrence of symptoms; the patient, during the interval, being, to all appearance, free from disorder: the various forms of ague are characteristically intermittent. *Local* diseases are opposed to those which are constitutional; they are presumed to be limited to some particular organ: the term "chronic disease" is sometimes misapplied in this sense. *Malignant* diseases are those which are of a highly dangerous and intractable character, and the symptoms of which are generally very formidable from the first; various forms of fever, rapidly depressing the vital energies, are said to assume a malignant type: hence also the term *malignant*, as generally applied to the Asiatic cholera. Local diseases are frequently malignant, such as cancer and ill-conditioned ulcers: all these are opposed to the *mild* forms of the same maladies. *Periodical*, diseases which recur at fixed periods, as in autumn, winter, &c. *Puerperal*, diseases incident to women soon after child-birth. *Specific* diseases are those which are marked by some disordered vital action not belonging to disease in general, but peculiar to the

individual case. *Sporadic* diseases are those arising from adventitious causes affecting the individual. *Sthenic* diseases are marked by the activity of the vital powers, directly opposed to those which are asthenic.

DISINFECTING LIQUOR. Solution of chloride of soda, or of chloride of lime.

DISJU'NCTIVE PROPOSI'TION, in Logic, is a proposition compounded of two or more categorical propositions, so stated as to imply that some of them must be true: — thus, " Either A = B, or C = D." A disjunctive, in which the two propositions are not naturally connected together in such a manner as to warrant their being proposed as alternatives, is nugatory and absurd in sense, although not incorrect in logical form. If one or more of the categorical antecedent propositions be denied, we infer that the remaining one, or, if there are more than one, some one of those remaining, is true: *e. g.* " Either A = B, or C = D; but A is not equal to B, therefore C = D." A poem is either good, bad, or indifferent: but it is not good; therefore, it is bad or indifferent. There are different forms of the *disjunctive syllogism*, founded on the disjunctive proposition.

DISK. In Botany, a term applied to certain bodies or projections, situated between the base of the stamens and the base of the ovarium, but forming part of neither, and taking a variety of forms. The disk is usually supposed to consist of rudimentary stamens, since an anther has been noticed to grow from that of *Pæonia moutan*, and in other cases manifest indications are observable of a tendency to assume the form of those organs.

DISLOCA'TION. (Lat. dislocare, *to put out of place.*) A surgical term, synonymous with *luxation.* " When the articular surfaces of bones are forced out of their proper situation, they are said to be dislocated or luxated. A considerable share of anatomical knowledge is required to detect the nature of these accidents; and it is much to be lamented that students neglect to inform themselves sufficiently upon the subject. (See *Sir A. Cooper's Surgical Essays*, i. p. 2.)

DISO'MUM. (Lat.) In Ancient Sculpture, a tomb made for the reception of the remains of two persons.

DI'SPART, in Gunnery, is the difference between the semidiameter of the base ring at the breech of a gun and that of the ring at the swell of the muzzle.

DISPE'NSARY. A place where medicines are made up and distributed; but used more generally for a charitable institution, where the poor are supplied with medicines and advice. Institutions of this nature are of comparatively recent origin; though they are now to be met with in every town of any importance both in this country and on the Continent. In London there are one or more dispensaries in each district; and to every dispensary there are always attached one or more physicians, surgeons, and apothecaries, whose duty it is respectively to prescribe and dispense medicines to the poor, and to visit them in their own houses in the event of their being too ill to attend personally at the institution. In most cases dispensaries are supported by voluntary contributions.

DISPENSA'TION. In Law, a licence granted by the bishop to a clergyman within his diocese to omit some particular of his duty; as, to hold two or more benefices, or to reside out of his parish. The name is peculiar to ecclesiastical law, and was formerly applied to the licences granted by the papal authority for several purposes; as, to marry within the prohibited degrees, &c.

DISPE'NSATORY. A word synonymous with Pharmacopœia (which see); signifying a book which describes the history, preparation, and composition of medicines.

DISPE'RSION. In Optics, a term used to denote the angular separation of the constituent rays of light when decomposed by the prism. In consequence of the unequal refrangibility of the different rays, a beam of light admitted through a small hole or slit in the shutter of a darkened room, and refracted by passing through a prism, forms an elongated image or spectrum; the red rays, which are the least refracted, occupying one end of the spectrum, and the violet rays, which suffer the greatest refraction, occupying the other end. The rays therefore, after refraction, are no longer parallel; so that the *index* of refraction (or the ratio of the sine of incidence to the sine of refraction) is different for each ray; and the difference of the indices for the extreme rays is called the *dispersion* of the light.

Sir Isaac Newton, who first examined the prismatic colours, was led by some imperfect experiments to suppose the dispersion proportional to the refraction; but it was soon discovered that although the colours in spectra formed by prisms of different substances are always arranged in the same order, they do not occupy the same relative lengths, — a prism of flint glass, for example, giving proportionally less red and more violet than a prism of crown glass; and that substances, for which the index of refraction of the middle ray of the spectrum is nearly the same, produce spectra of different lengths, or different amounts of dispersion. It is on this property namely, the irrationality of the refractive and dispersive powers of different substances, that the methods of forming achromatic lenses depend: had the supposition of Newton been correct, it would have been impossible to produce an image by refraction unaccompanied by the prismatic colours. *See* ACHROMATISM.

The difference between the indices of refraction of the extreme rays of the spectrum formed by a prism of any substance is called the *coefficient of dispersion* with respect to that substance, or simply the *dispersion;* and the *dispersive power* is the quotient which is obtained by dividing the coefficient of dispersion by the mean index of refraction diminished by unity. The *mean index* is that of the ray which corresponds to the middle of the spectrum. As these terms are of frequent occurrence in scientific works, we shall illustrate the definitions by an example. According to Sir D. Brewster, the index of refraction of diamond for the extreme violet ray is 2·467, and for the extreme red ray 2·411; the difference of these two indices is ·056, which, therefore, is the coefficient of dispersion for diamond. Again, the mean index, or mean of the above two numbers, is 2·439, which diminished by unity becomes 1·439; therefore the dispersive power of diamond is ·056 divided by 1·439, or ·0388.

For a table of the dispersive powers of a great number of different substances, see *Brewster's Optics*, in the *Cabinet Cyclopedia;* but we may remark, that as this table appears to have been constructed before the discovery of Fraunhofer's method of determining the indices of refraction by means of the dark rays in the spectrum, it rests on data subject to great uncertainty. *See* REFRACTION; also LIGHT, OPTICS, and SPECTRUM.

DISPLUVIA'TUM. (Lat.) In Ancient Architecture, a place in which the rain is conveyed away in two channels. A cavædium displuviatum, according to Vitruvius, was an open court exposed to the rain.

DISPOSI'TION. (Lat. dispositio.) In Architecture, one of the six essentials of the art. It is the arrangement of the whole design by means of ichnography (plan), orthography (section and elevation), and scenography (perspective view); and differs from distribution, which signifies the particular arrangements of the internal parts of a building.

DISQUISI'TION. (Lat.) An inquiry into the nature and properties of any problem, question, or subject, in the view of gaining or communicating correct information respecting it.

DISSE'CTION. (Lat. disseco, *I cut asunder.*) Signifies literally the cutting to pieces of any organized body with a view to elucidate its structure and functions. *See* ANATOMY.

DISSE'ISIN. In Law, a species of wrongful ouster or putting out of him who is seised of the freehold in lands: it is either *single disseisin*, or *disseisin by force*, more properly termed *deforcement.*

DISSE'NTERS. Persons who dissent on religious grounds from the usages and formula of the established church in England. Roman Catholics, however, are generally referred to as a distinct class, and the term Dissenters applied to Protestants only.

The first dissenters from the church of England were the Puritans, who, at the beginning of the reign of Elizabeth, complained of the use of the surplice, the sign of the cross in baptism, and some other relics, as they esteemed them, of popery. The laws of Elizabeth, however, required their attendance at church under severe penalties; and no opportunity was allowed them, even though they held episcopacy itself in abhorrence, of forming separate sects or congregations. Perhaps the first distinct sect of dissenters were the Brownists, who adopted very extreme opinions on the subject of church government, and against whom the punishment of death was enacted, as denying the queen's supremacy in ecclesiastical matters. On the accession of James an attempt was made by the puritanical party within the church to obtain a relaxation in some points of doctrine and discipline; but the conference at Hampton Court, which was convened upon that occasion, separated without effecting more than a few trifling alterations in the services. The penal laws continued in force, and Dissenters were not recognized as a distinct body by the state. They may be said to owe their origin in this sense to the assembly of divines convened by authority of parliament at Westminster in 1643, when a body of 120 clergymen and 30 laymen met and established the Presbyterian forms of doctrine and government, as set forth in the book called the *Directory*. The Independent party did not entirely accede to this settlement, and created some disturbances during the Protectorate. At the Restoration, the Presbyterian clergy were ejected on St. Bartholemew's-day, 1662, by the Act of Uniformity, which re-established the Liturgy, and was attended with some circumstances of aggravation and harshness. Two thousand non-conforming clergy were thereby ejected from their benefices. The Corporation Act, requiring attendance on the sacrament preparatory to accepting municipal offices, was also passed at the beginning of this reign; and the Test Act followed, which

excluded Dissenters in like manner from all places of trust and profit under government. These laws were repealed by 9 G. 4.; and Dissenters are now required only to make a declaration, according to the form of the act, that they will not exercise any influence they may possess by virtue of such office to injure or weaken the church by law established. The Act of Toleration (1 W. & M.) had long since abrogated the penal laws of Elizabeth against Dissenters, excepting Papists and such as deny the Trinity.

DISSE'PIMENTS. In Botany, the partitions that are formed in ovaria by the united sides of the cohering carpella, and which separate the inside into cells; also called *septa*.

DISSERTA'TION. (Lat.) An oral or written examination of any question or subject under some general or particular view. Perspicuity, simplicity, and methodical arrangement are the most essential qualities of a good dissertation.

DI'SSIDENTS. In modern European History, a term applied in Poland to those dissenters from the established religion (Catholic) who, under the old republic, were allowed the free exercise of their faith; including Lutherans, Calvinists, and Greeks, but excluding various minor sects. Their rights were fixed by the Religious Peace (pax dissidentium) of 1573, but they were infringed upon in the 18th century by various princes. They were supported in demanding the repeal of these restrictions by Russia and Prussia (in 1766), and hence those powers acquired one of their favourite pretexts for interference in the affairs of the Polish nation. Their rights were restored in 1775, with some exceptions; but after the Russian conquest they were placed on the same footing with the Catholics.

DI'SSONANCE. (Lat. dissonans, *discordant*.) In Music, a false consonance or concord. The same as discord.

DISTE'MPER. A disease of the dog. The distemper in dogs is commonly considered as a catarrhal disorder, and in general a running from the nose and eyes is one of the first and leading symptoms; it is usually accompanied by a short dry cough, and succeeded by wasting of the flesh and loss of strength and spirits. The nasal defluxion, which is at first watery, becomes after some days, or perhaps weeks, mucous and purulent, loading the eyes and obstructing the nostrils; the cough becomes more distressing, and is attended by an effort compounded of coughing and vomiting; the listlessness, wasting, and loss of appetite also increase.

If the disease be virulent, symptoms of affection of the brain are its frequent concomitants, attended by fits, and great debility and paralysis of the extremities, or by convulsive twitchings resembling St. Vitus's dance; and such is the induced irritability of the animal at this period, that an angry menace, or the sight of another dog in a fit, will often bring one on; and fondling and encouraging a dog under these primary attacks will shorten their duration, or altogether check them. If they continue, and increase in violence and frequency, they commonly prove fatal. "When the epileptic fits," says Mr. Blaine, "have gained their full hold on the dog, a partial or total mental alienation takes place; when total, the poor brute is often perfectly phrenitic; he waters and dungs unconsciously; he tears up the ground, bites every thing around him, and not unfrequently himself also. When the fit is over, he shakes himself, and looks and acts as usual, unless the attacks have been very violent and long-continued, when they leave him greatly exhausted and dispirited." In some of these attacks the dog walks round and round, unconscious of every thing about him. In such cases, the unfortunate animal is often supposed to be mad, and is frequently sacrificed accordingly; "but the suddenness of the seizure ought to inform the looker-on of the total impossibility of its being *rabies*, which is always in the worst cases marked with some recollection, some knowledge, and which never exhibits the indiscriminate fury which characterizes epilepsy."

Inflammation of the lungs is by no means an unfrequent consequence of distemper; and the bowels are always more or less affected by diarrhœa and dysenteric discharges, often indicating ulceration of the intestinal canal, and accompanied by bloody mucus and extremely offensive evacuations.

Protracted cases of distemper are sometimes attended by a pustular eruption on the abdomen and chest, accompanied sometimes by an hepatic affection, called by sportsmen, the *yellow disease*, from its giving the whole surface of the body a yellow hue: these are almost always fatal symptoms.

The danger and fatality of this disease depend upon so many causes that it is extremely difficult to prognosticate the results; young dogs and puppies seldom survive, and it is generally fatal to weakly and delicate dogs, and more so in town than in the country. Early in the disease a single fit is not alarming; but one or more fits in the advanced stages are seldom followed by recovery: impatience of light, red eyes, pneumonic attacks, and obstinate diarrhœa, are all bad symptoms; and spasmodic twitchings, a yellow tinge of the skin, and a pustular eruption, are in almost all cases the forerunners of death.

Laxatives, emetics, and occasional bleeding, are the leading remedies in the early stage of this disease; obstinate diarrhœa should be checked by astringents; and warm bathing, and anti-spasmodics must be resorted to to quell the violence of the fits.

The distemper is communicated by the contact of the diseased catarrhal secretion, and it may also be given by its inoculation; inoculation has indeed been proposed as a mitigation of the disorder, and it has been asserted that vaccination is a preventive. But it has been proved by Mr. Blaine that vaccination is quite inefficacious; and that inoculation with the matter of distemper is equally inefficient in mitigating the complaint, even when it is borrowed from the mildest forms. Many dogs, indeed, which have taken the disease by inoculation have had it with peculiar severity, and several have sunk under it. (See *Blaine's Canine Pathology*.)

DISTEMPER. In Painting. *See* DESTEMPER.

DI'STICH. (Gr. διστιχον.) A couplet of verses. In the Greek, Latin, and German languages, distich is applied to pieces of poetry consisting of two lines, in hexameter and pentameter verse.

DISTICHI'ASIS. (Gr. δις, *twice*, and στιχος, *a row*.) A double row of eyelashes, the innermost of which excite a constant irritation of the eye. The term *trichiasis* is generally applied to this malformation.

DI'STICHOUS. (Gr.) A term applied to the arrangement of organs in two rows, the one opposite to the other, as the florets of many grasses.

DISTILLA'TION. (Lat.) The evaporation and subsequent condensation of liquids by means of a *still* and *refrigeratory*, or of a *retort* and *receiver*.

The discovery of the art of distillation is generally ascribed to the alchemists; but it was doubtlessly known in more remote ages to the Arabians, and by them probably derived from nations further east.

The process of distillation, though in continual use in the chemical and pharmaceutical laboratory, is carried on upon the most extensive scale for the production of ardent spirits in the *distilleries*. Under the words ALCOHOL, BRANDY, FERMENTATION, WINE, &c. will be found some details bearing upon the nature, sources, and production of spirituous liquors; in the present article, therefore, we shall limit ourselves to an outline of the different processes which are more exclusively conducted in the British distillery.

There are two distinct operations in the production of ardent spirits: the one is the conversion of certain vegetable principles into alcohol; and the other, the separation of the alcohol from the other substances with which it is necessarily blended during its production.

The vegetable principle which is essential to the formation of alcohol is *sugar;* and this is sometimes used *directly*, as where molasses and analogous saccharine products are subjected to immediate fermentation; or it is *indirectly* obtained by subjecting amylaceous grains to certain processes, by which the starch they contain is first converted into sugar, and then that sugar afterwards alcoholized.

In our distilleries the latter alternative is adopted; and various kinds of grain, but chiefly barley, wheat, and rye, with more or less malt, are subjected to the operation of *mashing*. For this purpose the ground grain and the bruised malt are duly mixed, and infused under constant agitation in a proper quantity of hot water in the *mash-tun;* the wort is then run off, and fresh water added, till the soluble materials of the grain are extracted.

In this way the mixed worts or *wash* is obtained, which is afterwards to be subjected to fermentation; but in the distillery the operator is not, as in the brewery, left to his own judgment or convenience, but enforced to conform to the excise laws, which are of a very peremptory and often of a very unscientific character. By these laws the distiller is restricted in the density of his worts to specific gravities between 1050 and 1090; and in Scotland, between 1030 and 1075. It is presumed that at those specific gravities, which are called 50 and 90, and 30 and 75, the actual quantity of saccharine or saccharifiable matter contained in each barrel (or 36 imperial gallons) amounts respectively to from $47\frac{1}{4}$ lbs. to 85 lbs., and from 28 lbs. to $79\frac{3}{10}$ lbs. When the wash above alluded to is adjusted as to density, it is run into the fermenting vats, where, mixed with a small quantity of yeast, it is subjected to the process of fermentation, which continues from six to ten or twelve days, the time required for its completion varying with the mass of liquid and with the temperature of the atmosphere.

During mashing, as well as during fermentation, the starch passes into sugar, and the sugar into alcohol; the consequence of which is that the wash gradually decreases in density or *attenuates;* and as soon as this attenuation has reached its maximum, which may be determined by

the hydrometer, it should be distilled, in order to prevent the access of acetous fermentation.

In all large distilleries there are two sets of stills: one for the purpose of distilling from the wash a weak spirit, technically called *low wines;* and the other for redistilling (or *rectifying*) the low wines. In these distillations there passes over along with the first and last portions of the spirits a peculiar volatile oil of a disagreeable flavour and odour, and rendering the weaker spirit milky. These portions are called *faints*, and are carefully turned into separate receivers as soon as the appearance of the runnings from the worm end indicates their presence.

The quantity of alcohol which may be obtained from a given quantity of sugar will depend upon the skill and care with which mashing, fermentation, and distillation have been respectively conducted; theoretically, 100 pounds of sugar are convertible into about 51 of alcohol and 49 of carbonic acid. The quantity of alcohol to be procured from different kinds of grain will also depend upon the same causes, and upon the quantity of sugar, and of starch and gum convertible into sugar, which each may contain. According to Hermstædt 100 pounds of starch should yield 35 pounds of real alcohol; and 100 pounds of the following grains should yield the following quantities of spirit of the specific gravity of 0·9427; that is, of spirit containing 45 per cent. of real alcohol; namely, wheat 40 to 45 pounds, rye 36 to 42, barley 40, oats 36, buckwheat 40, maize 40.

Sometimes malt only is used in the distillery, in which case the distiller calculates in obtaining two gallons of whiskey of proof strength from each bushel of malt.

What is meant by the term *proof spirit* will appear obvious from the following extract from a report of a committee of the Royal Society respecting the improvement of the hydrometer. "With regard to the substance *alcohol* upon which the duty is to be levied, there appears to be no reason, either philosophical or practical, why it should be considered as *absolute* (that is, *pure*). A definite mixture of alcohol and water is as invariable in its value as absolute alcohol can be. It is also invariable in its nature; and can be more readily and with equal accuracy identified by that only quality or condition to which recourse can be had in practice, namely, *specific gravity*. A *diluted alcohol* is that, therefore, which we recommend as the only exciseable substance; and as on the one hand it will make no difference in the identification, and on the other will be a great commercial advantage, it is further recommended that the standard be very nearly that of the present proof spirit. The proposition, therefore, of your committee is, that *standard spirit* be that which, consisting of alcohol and water alone, shall have a specific gravity of 0·92 at the temperature of 62° Fahrenheit. This standard is rather weaker than the old proof spirit in the proportion of nearly 1·1 gallon of the present proof spirit per cent. But this difference is trifling compared with the convenience resulting from the adoption of the specific gravity 0·92, instead of that of the present proof spirit, which is 0·918633. It may be interesting hereafter to ascertain what proportion of *absolute alcohol* enters into the composition of the recommended standard spirit, but the point possesses not the slightest practical importance in reference to the present question."

The *proof spirit* of commerce, and that of the Pharmacopœia, is generally stated to be of the specific gravity of 0·920 at 62°, and is considered as a mixture of *equal weights of absolute alcohol of the specific gravity of* 0·791 *at* 60° *and of water*. The *rectified spirit* of commerce, or rather that of the Pharmacopœia, is directed to be of the specific gravity of 0·838 at 60°, and may be regarded as a mixture of about 82 parts of absolute alcohol and 18 of water.

The inquisitorial regime, observes Dr. Ure, imposed by law upon our distilleries might lead a stranger to imagine that our legislators were desirous of repressing by every species of annoyance the fabrication of the fiery liquid which infuriates and demoralizes the lower population of these islands. But, alas! credit can be given them for no such moral or philanthropic motive. The necessity of the exchequer to raise a great revenue, created by the wasteful expenditure of the state on the one hand, and the efforts of fraudulent ingenuity on the other, to evade the payment of the high duties imposed, are the true origin of that regime. Examinations in distilleries are constantly making by the officers of excise. There is a survey at six o'clock in the morning, when the officers take their accounts and gauges, and make calculations which occupy several hours. At ten o'clock they again survey, going over the whole premises, where they continue a considerable time, frequently till the succeeding officer comes on duty; at two in the afternoon another survey takes place, but not by the same people; at six in the evening the survey is repeated; at ten there comes another survey by an officer who had not been engaged in any of the previous surveys of that day. He is not relieved till six o'clock next morning. In addition to these regular inspections, the distilleries are subject to frequent and uncertain visits of the surveyor and general surveyor. "We are never," says Mr. Smith, the eminent distiller of Millbank, "out of their hands."

There can be no doubt that all the operations of our distilleries would be susceptible of infinite improvement by an alteration in the excise laws. As these at present stand, the duty is charged from calculations — 1. On the quantity and density of the wash; 2. On the quantity and density or strength of the low wines, or first products of distillation; 3. Upon the quantity and strength of the spirit, or, in other words, of the alcohol actually produced. It is presumed, in reference to the wash, that the alcohol which it will afford by fermentation will be directly as its density (without reference to the nature of the matter which it holds in solution). In low wines, and in the spirits, the proportion of alcohol is inversely as the density, and the duty is charged in conformity with experiments upon the composition of mixtures of alcohol and water of different densities.

Nothing need be said here of the mode of judging of the value of the wort by its attenuation during fermentation, nor of the fallacies to which the different operations are liable, and we are well aware of the danger and difficulties of meddling with so important a branch of the revenue; but it is impossible for any scientific person to visit our distilleries without at once seeing much that is susceptible of safe and effectual alteration; or to peruse the multitudinous documents, and the evidence which has been brought before the commissioners of revenue inquiry and before parliamentary committees, bearing directly or indirectly upon this subject, without an anxious wish that some remedy should be found for the evils which are there set forth. In every point of view two things seem highly desirable, and apparently not unattainable; the one is that the materials employed as sources of spirit, and the mode of conducting the operations of the distillery, should be, as far as possible, entirely unshackled; the other (a necessary consequence), that the duty should be levied upon the ultimate product at the worm end; or, in other words, upon the quantity of absolute alcohol actually produced, and that the charge should be made in reference to that alone.

In reference to further details regarding the operations of the distillery and their influence upon the revenue, the reader is referred to ***Dr. Ure's Dictionary of Arts and Manufactures***, art. "Distillation;" and to ***M'Culloch's Dictionary of Commerce***, art. "Spirits," which is enriched with numerous tables. See also the article SPIRITS in this work.

DI'STOMA. (Gr. δις, *twice*, and στομα, *mouth.*) The name of a genus of Trematodous intestinal worms, including those which have two suckers or organs of adhesion, of which the anterior alone is a true mouth; and the posterior or larger disc is situated on the ventral aspect of the body, a little way behind the mouth.

DISTO'RTION. (Lat. distorqueo, *I turn awry.*) An unnatural deviation of shape or position of any part of the body, producing visible deformity.

Some distortions are exclusively dependent upon disordered actions of the muscles or nerves, or both; certain kinds of lameness, for instance, arise from a want of due sympathy between the flexor and extensor muscles, or from an unnatural contraction of one or more muscles in consequence of the inefficiency of their opponents; hence various paralytic distortions, squinting, wry neck, and some forms of what is termed club-foot.

The most common cause of distortion, however, is disease of the bones, which, being sometimes deficient in their hardening or earthy principle, are incapable of supporting the weight of parts which they are designed to bear, or of sustaining pressure or muscular action, without more or less flexure. Of this kind is the disease called *rickets* (from ῥαχις, *the spine*), in which it has been presumed, though erroneously, that the vertebræ are the chief seat of the mischief. Besides rickets, there are other cases of curvature of the spine, the causes of which are by no means very obvious, more especially those of the *serpentine* or *lateral* curvature, which is not unfrequent among delicate girls in the higher and middling classes of life, though of very rare occurrence among the lower orders. This disease is usually observed about the ninth or tenth year, and the symptoms are generally traced in the following order:—1. The child makes frequent attempts to prevent the dress falling off one shoulder; 2. One shoulder appears higher than the other; 3. One of the collar-bones, or one side of the breast-bone, appears fuller than the other; 4. One hip appears to project; 5. One leg appears shorter than the other; 6. There is a peculiarity in the manner of walking, one foot being swung round and the shoulder thrown forward. When the girl reaches the age of twelve or thirteen (for this disease is *very rare* in boys), she becomes evidently twisted, and the spine is found to have assumed a serpentine form. In reference to the treatment of this kind of distortion, it appears that very opposite methods have been successful; thus, some patients have been confined for months to the same position; another violently exercised; another

shampooed and acupuncturated; a fourth relies on artificial supports, such as stays and bandages; a fifth is leeched or blistered; and many are told to attend only to the general health. The truth is, that distortion may depend upon different causes, and different remedies may be required in its different stages of progress. The serpentine curvature of the spine generally originates in muscular debility; and therefore, at its commencement, is appropriately treated by attention to the general health, by proper exercises and tonics. As the disease, however, proceeds, the muscles and ligaments acquire a certain form, and then artificial supports may be appropriately resorted to. In a yet more advanced stage, the vertebræ themselves become altered in form; and hence the spine may require to be stretched, and kept so during a considerable part of the twenty-four hours, so as to allow the bones to resume their natural form. When the ribs and sternum have become much displaced and misshapen, methods of compressing and remodelling them must be adopted; and lastly, when what is called *anchylosis*, or permanent bony deformity, has taken place, palliations and preventives of further mischief can alone be resorted to.

In all cases where there is a tendency to distortion, its early progress should be watched with the utmost solicitude, and *preventive means* steadily and perseveringly adopted. When a girl is eight or ten years old, she should not be confined to the school room, and to a walk once or twice a day, but she should be induced by amusing and romping games to use active exercise, and especially such as brings the muscles of the trunk into play; she should not be kept long at the piano-forte, and her chair should be made so as to support her. If she has a tendency to lean to one side, she should be allowed to learn her lessons in a recumbent posture, and not constantly admonished to "hold herself up." By attention to these simple rules at a very early period of this tendency to distortion, its further progress may be possibly prevented; but if the girl becomes listless, lounging, and pallid, appearing awkward in her gait, and the clothes slip off of one shoulder, the spine is probably becoming distorted; and in this case she should not be allowed to sit erect without using some artificial support, such as an arm-chair, or chair crutch, and she should read always lying down; while by the help of proper stays and a belt support should be given to the loins, while the upper part of the chest is left free. No shoulder-straps, collars, or back-boards should be used to push in the projecting shoulder, unless the loins be at the same time supported; for in the majority of cases a sinking of the lumbar part is the cause of the inequality of the shoulders. The child should, in this stage of the disorder, be a good deal in the open air; not walking sedately, but, if possible, skipping about; and when she comes in, should not lounge on a chair, but lie down; or if out-of-door exercise is inadmissible, she should play at battledore and shuttlecock, and use a skipping rope. But whatever exercise be used, it should never be carried to fatigue. The child should sleep on a firm hair mattress, with scarcely any pillow; she should have good nourishing diet; occasional warm aperients and alkaline tonics may be proper; and cold bathing or sponging. By scrupulously following up the preceding plan, the general health is improved, and the tendency to distortion often diminished; but constant care for months, and even years, can alone ensure its removal. Where the spine has acquired a decided twist, a variety of mechanical contrivances, and many different plans of treatment, have been proposed and used with more or less success, with a view of correcting the deformity, or preventing its increase and improving the figure. For an account of these we must refer to the authors who have expressly treated upon these subjects, and especially to the sensible tract of the late Mr. John Shaw, from which we have abridged the preceding remarks.

There is another kind of distortion, differing entirely from the preceding; namely, *angular curvature* of the spine. It generally proceeds from scrofulous ulceration of the bodies of the vertebræ; it is attended with paralysis of the lower extremities, and is often fatal. Similar disease often occurs in the other bones and joints of the body.

There are a variety of deformities resulting from other causes than those above adverted to; namely, from gout, rheumatism, and various chronic and local affections, which, however, do not come under the general term of *distortions:* nor can we properly refer to this head a variety of real deformities which are chiefly the consequence of dress and fashion; such as those which result from wearing stays, bandages, ill-made and tight shoes, and the like.

DISTRA'CTILE. In Botany, a term invented by Richard to denote a connective which divides into two unequal portions, one of which supports a cell and the other not, as in *Salvia*.

DISTRE'SS, in Law, is the taking of a personal chattel out of the possession of a wrongdoer into the custody of the party injured, to procure satisfaction for the wrong committed.

Distress may be had for various kinds of injuries, and as a means of enforcing process, or the performance of certain acts in various cases. But the most usual injury for which a distress may be taken is that of non-payment of rent. Distress for rent is said to be incident to the reversion; so that it may be taken for rent reserved upon a gift in tail, lease for life, years, &c., though there be no clause of distress in the deed, if the reversion is in the party distraining. Distresses are to be of things valuable, wherein some one has a property. But various species of personal chattels are exempt from distress, especially the utensils and instruments of a person's trade and profession, if in actual use, otherwise they are not privileged. All distresses for rent must be made by day, and on the premises; but if any tenant fraudulently removes goods from off the premises, the landlord may within thirty days seize such goods wheresoever found, unless they are sold for a valuable consideration before the seizure. Persons who distrain for rent may sell the distress for payment of rent in arrear, if the tenant or owner fails to replevy, with sufficient security, within five days after taking the distress and giving the tenant notice of the cause. In this case the constable is bound to assist; the goods are to be appraised by two sworn appraisers; and the overplus, if any, left in the constable's hands for the use of the owner.

DI'STRICT. A territorial division. This term was formerly used in France, and particularly in the year 1790, when by the law of 16th Feb. the whole country was divided into 555 districts; and it is still common to many of the Continental states. The county of Lincoln is divided into three districts; Lindsey, Kesteven, and Holland. These divisions are of great antiquity, and in all probability owe their origin to the distinct natural features by which they are characterized.

DITHYRA'MBIC ODE. (Gr. διθυραμβος.) A species of Greek lyrical poem in honour of Bacchus, which derived its name from Dithyrambus (Διθυραμβος), one of the appellations of that deity: a word of uncertain meaning and etymology. The style of this poetry was very bold, often passing into bombast; so much so indeed as to become proverbial for the latter quality. The most celebrated Dithyrambic writer was Pindar; none of whose compositions in this line, however, have come down to us, or indeed any other known poems of this class. In modern times the term is indiscriminately employed to designate odes of an impetuous and irregular character. *See* ODE.

DI'TONE. (Gr. διτονος.) In Music, an interval consisting of two tones.

DI'TRIGLYPH. (Gr. δις, *twice*, τρεις, *three*, and γλυφω, *I carve.*) In Architecture, an arrangement of intercolumniations in the Doric order, by which two triglyphs are obtained in the frieze between the triglyphs that stand over the columns.

DI'TTO, in Book-keeping, more usually contracted into *Do*, signifies *the same* as that which precedes it. It is derived from the Italian word *ditto*, signifying *the said*.

DI'TTY. (Fr. ditie.) A word of great antiquity in the English language, signifying most usually a simple or pastoral song. Thus Milton says—

> Meanwhile the rural ditties were not mute,
> Tempered to the oaten flute;
> Rough satyrs danced, &c.

Shakespeare, Dryden, and many of the old classic English writers, have repeatedly given importance to this word.

DIURE'SIS. (Gr. διουρησις, *a discharge of urine.*) An excessive flow of urine. *See* DIABETES.

DIURE'TIC, signifies literally any thing which increases the secretion of urine. The term is usually applied to certain medicines which act specially upon the kidneys, such as squills, turpentine, and some of the neutral salts; and it frequently happens that during an inordinate flow of urine derived from such causes watery fluids are absorbed from other parts, and, as it were, transposed to the kidneys: upon this principle is founded the use of diuretics in dropsy. There are some alteratives which operate as diuretics, especially when they are taking a favourable operation upon the system: this seems especially to be the case with sarsaparilla. Water and other diluents and liquids, when taken in excess, also operate as diuretics; as far, at least, as mere increase in the flow of urine is concerned.

DIU'RNAL (Lat. dies, *a day*), is the name given to the book containing those canonical hours of the Roman Catholic breviary which are to be said during the day. It is intended especially for the clergy of the Romish church, and consists generally of four volumes, one for each season of the year.

DIU'RNALS. (Lat. diurnus, *by day.*) A tribe of Raptorial birds, including those which fly by day and have lateral eyes: also a family of Lepidopterous insects, which have a similar period of activity.

DIVA'N. A word common to many of the eastern languages, signifying in Turkish the audience-chamber of the vizier, or supreme judicial tribunal. The divan of

the caliphs was a court for the relief of petitioners, over which those monarchs presided in person. The Turkish divan, as is well known, is the great council of the empire.

It would seem that the earliest acceptation in which this word was employed is that of a muster-roll or military day-book; and we find it used, especially by the ancient Arabs, who borrowed it from the Persians, to signify a collection of poems by one and the same author, arranged in alphabetical order; thus we hear of the Divan (*i.e.* the collected poems) of Sadi, the Divan of Halfiz, &c. The word *divan* is also among the Turks a common appellation for a saloon or hall which serves for the reception of company, for the transacting of business, or for occasional repose; hence in all probability the term is employed in all modern languages to signify a sofa.

DIVA'RICATE. (Lat. divarico.) In Zoology, when the divisions of a part spread out widely.

DIVE'RGENT. (Lat. divergo.) In Zoology, when the branches form a right angle with the stem; as the snags of certain antlers, the divisions of certain Polypiaries, &c.

DIVE'RGING. In Botany, used in describing the venation of leaves, to denote the angle which is formed by the midrib and one of the primary veins, when it is between 20° and 40°.

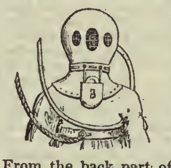
DI'VIDEND. (Lat. divido, *I divide.*) In Arithmetic, the number or quantity given to be divided. Dividend, in Commerce, is the name given to the payment made to creditors out of the estate of a bankrupt, and to the annual interest payable upon the national debt and other public funds.

DIVINA'TION. (Lat.) The art of foretelling future events. A singular and ever-active feeling of curiosity has in all ages induced mankind to cast an anxious look towards futurity in the desire of penetrating its mysteries, originally either by serious reflections on the past, by a comparison of the past with the present, or by inferences more or less satisfactorily deduced from the probable occurrence of events. But mankind did not rest here: since the remotest period of antiquity, divination formed a regular science, intimately allied to religion, and furnished with peculiar rules and regulations, more or less skilful and ingenious in proportion to the state of civilization of the people by whom it was practised. But of all the nations of antiquity there were none who, notwithstanding their great learning and refinement, cultivated the science of divination with such enthusiasm as the Greeks and Romans. Independently of their credulity with regard to auguries and oracles, which may be termed the higher class of divination, the most trifling incidents supplied them with the occasion to indulge in this propensity; and there was nothing in the wide range of human affairs from which they did not derive tokens of futurity. To enumerate all, or even the chief objects of divination among the ancients, would far exceed our prescribed limits. Under the different heads, as BELOMANCY, NECROMANCY, &c., the reader will find a notice of the principal of them; and for the rest he may consult with advantage Cicero, *De Divinatione*. *See* ORACLE.

DIVINE RIGHT, THE, OF KINGS. In Politics, means the absolute and unqualified claim of sovereigns on the obedience of the people; insomuch that, although they may themselves submit to restrictions on their authority, yet subjects endeavouring to enforce those restrictions by resistance to their unlawful acts are guilty of a sin. This doctrine, so celebrated in English constitutional history, has been asserted on very different grounds. Hobbes (*De Civ.*) deduced the absolute authority of kings from the supposed social contract, whereby men parted absolutely with their natural rights in exchange for protection. But the fashionable political writers and theologians of the times both of Charles I. and II. (in the latter reign, Sir Robert Filmer, author of the *Patriarcha*, may be more especially cited, on account of his having been directly answered by Leslie), maintained that government had an existence before property, and before any supposed social contract could take place; that it originated in the patriarchal sway, which was succeeded by the regal, and that no other was authorized by Scripture. See also the *Convocation Book* of 1603; Archbishop Leslie on the *Power of the Prince;* Sherlock's *Case of Resistance to Supreme Powers*, 1684; Mackenzie's *Jus Regium*, 1683. The same principles were practically adopted by the Jacobites, when they maintained the divine right of the expelled sovereign, and afterwards of his descendants, by hereditary title. As to the views of modern high church divines on the subject, see *Dr. Pusey's Sermon on the 5th of November*, 1837. *See* NON-RESISTANCE.

DI'VING. The art of descending in water. Independently of the valuable native productions which are found at the bottom of the sea, such as pearls, coral, sponges, &c., the treasure which is so frequently carried down in wrecked vessels makes it an object of importance to be able to descend to the bottom and remain there long enough to execute the operations necessary to recover it. But without the assistance of some mechanical apparatus, it is extremely little that even the most practised divers can perform. A minute and a half, or two minutes, is the longest time that a diver, in general, can remain under water. Besides, on account of the loss of weight in water, the power which a man can exert is extremely small, unless borne down by a load which would entirely prevent him from rising again to the top. For these reasons, numerous projects have been brought forward to assist the natural powers of the body, and render diving an art of more extensive utility. In all these projects, the principal object aimed at is to supply the diver with fresh air and light, and leave him the free use of his arms, and the power of walking within a moderate range at the bottom. Borelli contrived an apparatus which he called a diving bladder; the bladder being of brass or copper, about two feet in diameter, to contain the diver's head, and fastened to a goat skin covering exactly fitted to the shape of the head. An apparatus of this kind was successfully used by Mr. Deane on the west coast of Scotland, at Spithead, and at Donaghadee, where he brought up an immense number of dollars and various other articles from a vessel which had been wrecked there more than thirty years before.

The principal part of Mr. Deane's apparatus consists of a helmet of thin sheet copper, which covers the head of the diver, large enough to admit of free motion, and furnished with three eye-holes, covered with glass protected by brass wires. The helmet comes pretty well down over the breast and back, and is fastened by rivets to a water-proof canvass jacket so tightly that no water can penetrate. A leather belt passes round the diver, to which are attached two weights, one before and the other behind, each about 40 lbs. The belt is supplied with a buckle in front, which, in case of any accident happening, can be instantly undone. The diver is supplied with fresh air, by means of a flexible water-proof pipe, which



enters the helmet, and communicates with an air-pump, wrought above in the barge from which he descends. This pipe passes under the left arm of the diver, and enters the back of the helmet, being so contrived that the fresh air is made to impinge on the glasses; which in a great measure prevents their being dimmed by the moisture of the breath. From the back part of the helmet there is also led an eduction pipe, to allow the escape of the breathed air. A signal line passes under the right arm to communicate with attendants at the surface. The diver descends from the side of the vessel, either by means of a rope or wooden ladder, loaded at the lower end, the weight being kept at a little height above the ground. When the diver descends to the bottom, the weight is let down, and the rope allowed to become slack, to prevent the motion of the boat from obstructing him. His motion is rendered steady by heavy weights attached to his feet; and he carries a line in his hand, that he may, when necessary, guide himself back to the rope. A waterproof dress covers his body entirely; and he is thus enabled to remain under water five or six hours at once, all the while perfectly dry. (See *Popular Encyclopædia*, art. "Diving.")

DIVING BELL. An apparatus, by means of which persons are let down and enabled to remain under water, and execute various operations; such as levelling or clearing the bottoms of harbours, preparing a foundation for buildings, bringing up sunken materials, &c. The principle of the diving bell depends on the impenetrability of atmospheric air, and may be illustrated by a very familiar experiment. Bring the edge of an inverted tumbler, or any close vessel, to the surface of water, and, keeping the mouth horizontal, press it down in the water. It will be seen that, though some portion of water ascends into the tumbler, the greater part of the spacer emains empty, or only filled with air; and any object placed in this space, though surrounded on all sides with water, would remain perfectly dry. In fact, the quantity of air remains the same, but is compressed into a smaller volume, in proportion to the depth to which it is made to descend. Now, if we conceive a vessel of wood or iron, sufficiently capacious to hold several men, to be suspended by a chain, and lowered by means of weights attached to it to any moderate depth under water, it is evident that they may remain there for a considerable time, and perform any operation that could be executed on land in the same confined space. The machine, however, as thus described, is liable to two great defects, which must be obviated by other contrivances before any great advantage can be derived from it. In the first place, as the air by its compressibility allows the water to enter the lower part of the bell, the dry space is not only diminished, but the bottom on which the bell rests, and where the operations are to be carried on, is also covered with water to a proportional depth. In the second place, the air within the bell, by repeated respiration, soon becomes mephitic, and unfit to support life; so that it is necessary to elevate the apparatus after short intervals, to admit a fresh supply.

It is not known at what period the diving bell was invented. Beckman, in his *History of Inventions*, mentions that at Toledo, in the sixteenth century, two Greeks, in the presence of the emperor Charles V. and several thousand spectators, let themselves down under water in a large inverted kettle with a burning light, and rose again without being wet. George Sinclair, the author of *Satan's Invisible World Displayed*, in his work entitled *Ars Nova et Magna Gravitatis et Levitatis*, mentions some attempts that were made, about the year 1665, to raise, by means of a diving bell, the treasure from the ships of the Invincible Armada that went to the bottom near the Isle of Mull in the Hebrides, and describes the kind of bell that was employed. But, on account of the defects to which we have alluded, the diving bell continued to be of very little use till the time of Dr. Halley, who contrived a means of introducing fresh air into the bell while under water, and of allowing the mephitic or breathed air to escape. The bell he made use of he describes as having been of wood, containing about 60 cubic feet in its concavity, and of the form of a truncated cone, whose diameter at the top was three feet, and at the bottom five. This was coated with lead, so heavy that it could sink empty, and the weight so distributed about its bottom that it could only descend in a perpendicular direction. In the top a clear glass was fixed, to let in the light from above, and a cock to let out the air that had been breathed. To supply the air to the bell he caused a couple of barrels, of about 36 gallons each, to be cased with lead so as to sink empty, each of them having a bung-hole in its lowest part, to let in the water as the air in them condensed on their descent, and to let it out again when they were drawn up full from below. To a hole in the uppermost part of the barrels a trunk or hose was fixed, long enough to fall below the bung-hole, and kept down by a weight, so that no air could escape by the hose till its end was raised up. The barrels thus prepared were let down by the side of the bell. A man stationed on a stage suspended from the bell was ready to take up the hose; and, as soon as their ends were brought to the surface of the water in the barrels, all the air that was included in the upper parts of them was blown with great violence into the bell, while the water entered at the bung-holes below and filled the barrels. By means of this contrivance the air was not only kept fresh, but another great advantage was gained; namely, that by admitting a sufficient quantity of it the whole of the water was expelled from the inside of the bell, and the bottom of the sea laid dry.

By means of this contrivance for the admission of fresh air, it was now possible to remain for any length of time under water; but the use of the apparatus was still found to be attended with some inconveniences, and even considerable danger. The divers within the bell having no power over it, its rising or sinking depends entirely upon the people at the surface of the water; and as the bell, even when in the water, has a considerable weight, there is always a possibility of the chain by which it is raised breaking, which would inevitably be attended with the destruction of the divers. Another danger, still more to be apprehended, is, that if the mouth of the bell in its descent should come upon a sunken ship, or a rock projecting abruptly from the bottom, it might be overset before any signal could be given to those above. These defects were obviated by the very ingenious contrivances of Mr. Spalding of Edinburgh. In order to avoid the risk of being upset when the bell descends on a rocky or uneven bottom, he suspended a considerable weight, which he called a *balance weight*, below the bell, by a rope passing over a pulley fixed in the inside; and the other weights attached to the bell being so adjusted that they could not sink it without the balance weight, as soon as the latter rested on the ground the bell remained suspended in the water. In case of the mouth of the bell being caught by any obstacle, the balance weight is immediately lowered, till it rests on the bottom; and as the bell, when thus relieved, is buoyant, the divers, having disengaged it from the rock, have it in their power either to descend by pulling in the rope, or by allowing it to run to ascend to the surface. Another contrivance of Mr. Spalding deserves mention. He divided the bell into two compartments, the one above the other, and communicating by means of a stopcock. The divers are stationed in the lower one, and the weights are so adjusted that when the cavity above is empty the bell is buoyant; when it is filled with water, the bell sinks. Immediately above the partition are some slits in the sides of the bell; and at the top is an orifice, which can be opened or shut at pleasure. Suppose now, this orifice being open, the bell is required to be lowered; as it descends, the water enters at the slits, and the air escapes by the orifice. When the apparatus is entirely under water, and the cavity consequently completely filled, let the orifice be shut. The bell will now continue to descend; but if the stopcock communicating with the upper compartment be opened, the air will rush from the under to the upper, and displace a quantity of the water, and the apparatus will be lightened by the whole of the water so displaced. The divers have it thus in their power to regulate the descent or rise as they please. By admitting a certain quantity of air into the upper cavity, the descent of the bell is arrested; by admitting a greater quantity it becomes buoyant, and rises to the top. This method of constructing the diving bell has not, however, been adopted.

The greatest improvement on the diving bell, since that of Halley, was made by the celebrated Mr. Smeaton, and consists in forcing down a continued stream of air by means of an air pump through a flexible tube; and this plan is now always adopted. In the year 1788, Mr. Smeaton constructed a diving bell to be used in the operations then contemplated at Ramsgate harbour on a new and improved plan. Instead of a bell-shaped vessel sunk by weights, his apparatus consisted of a square chest of cast iron, four and a half feet long, four and a half feet high, and three feet wide, affording sufficient room for two men under it. It was cast of such a thickness that its own weight was sufficient to sink it; and its thickness was greatest near the mouth or lower part, to prevent it from being easily overset. This construction of the diving bell gave the men within it no power of raising or sinking it; but as the apparatus was made to be used at a place where the nature of the bottom was known, this advantage was not considered of great consequence; and, in fact, it is found by experience that it is better to leave the bell to be entirely guided from above. On account of the facility with which water conveys sound, the strokes of a hammer on the inside of the bell can be heard at a great distance; and the sound coming through the water has a peculiar character, which cannot be mistaken. By previous arrangement any directions can be given in this manner. For instance, one blow may denote more air; two, stand fast; three, heave up; four, lower down, and so on. With these successive improvements, the diving bell is found to be a most important machine in all great operations to be performed under water. It was used with great advantage by Mr. Rennie in the construction of the various harbours he projected; and it has recently been successfully employed in deepening the Clyde between Glasgow and Greenock, and improving the navigation of the river. See the article "Diving Bell," in the new edition of the *Encyclopedia Britannica*.

DIVI'NING ROD. *See* RABDOMANCY.

DIVI'SIBILI'TY. The property which all bodies possess of being separable into parts. It was a question formerly much agitated among philosophers, whether matter is divisible *in infinitum*; or whether a certain term does not exist beyond which the particles are reduced to simple atoms incapable of further division. The question is incapable of direct solution, and fortunately is of no importance to science; but the extent to which the actual subdivision of bodies has been carried in many cases in the arts may well be considered as prodigious. "In the gilding of buttons, 5 grains of gold, which is applied as an amalgam with mercury, is allowed to each gross; so that the coating left must amount to the 110,000th part of an inch in thickness. If a piece of ivory, or white satin, be immersed in a nitro-muriate solution of gold, and then exposed to a current of hydrogen gas, it will become covered with a surface of gold hardly exceeding in thickness the ten-millionth part of an inch."

"The solution of certain saline bodies, and of other coloured substances, exhibits a prodigious subdivision and dissemination of matter. A single grain of the sulphate of copper, or blue vitriol, will communicate a fine azure tint to five gallons of water. In this case the copper must be attenuated at least ten million times; yet each drop of the liquid may contain so many coloured particles, distinguishable by our unassisted vision. Odours are capable of a still wider diffusion. A single grain of musk has been known to perfume a room for the space of twenty years. Animal matter likewise exhibits in many instances a wonderful subdivision. The milt of a codfish when it begins to putrefy has been computed to contain a billion of perfect insects, so that thousands of these living creatures could be lifted on the point of a needle. But the infusory animalcules display in their structure and functions the most transcendent attenuation of matter. The *Vibrio undula*, found in duck weed, is computed to be ten thousand million times smaller than a hemp seed. The *Vibrio lineola* occurs in vegetable infusions, every drop containing myriads of these oblong points. The *Monas gelatinosa*, discovered in ditch water, appears in the field of a microscope a mere atom endued with life, millions of them playing like sunbeams in a single drop of liquid." (*Leslie's Natural Philosophy.*)

DIVI'SION. (Lat. divido, *I divide.*) One of the four fundamental rules of arithmetic, the object of which is to find how often one number is contained in another. The number to be divided is the *dividend*, the number which divides is the *divisor*, and the result of the division is the *quotient*. Division is the converse of multiplication.

DIVI'SION. In Music, a dividing or separation of the interval of an octave into a number of lesser intervals.

DIVI'SION, in Logic, is the enumeration of several things signified by a common name; thus, tree is said

to be divided into oak, ash, elm, &c. A common term may be divided in several ways, according to the various points of view in which it may be regarded for the purpose of qualification. Thus a bookbinder may divide books into folios, quartos, &c.; a librarian into theological, historical, &c.

Division, in the art Military, signifies generally a certain proportion of an army, consisting of cavalry and infantry together or separately, that is, under the order of a brigadier or other general officer; but, in a more restricted sense, it is applied to any number of men on military duty detached from an established body, as a division of artillery, pioneers, &c. The divisions of an army are the number of the brigades and squadrons of which it consists; the divisions of a battalion are the several platoons into which a regiment or battalion is divided either in marching or firing. (*James's Mil. Dict.*)

DIVO'RCE. (From the modern Latin word divortiare, *to turn or put away.*) The Jewish law of divorce is founded on the directions given in the 24th chapter of Deuteronomy; but the permission therein contained is subject to many obstacles and formalities in modern practice. In Greece, in classical times, the practice of divorce seems to have varied in different states; at Sparta it appears to have been unusual, in Athens great facilities were afforded by the law. In republican Rome great strictness in this branch of morals prevailed for a long period, although parties were less impeded in pursuing a divorce by the difficulties imposed by the law than by public opinion. But in the later period of the republic, and under the emperors, divorce became extremely common, and was obtained with equal ease by either sex. Our Saviour's declaration to the Pharisee, in the 19th chapter of St. Matthew, became the foundation of the law on this subject in Christian countries, and divorces were consequently allowed in one particular case only; but after the Roman church had erected matrimony into a sacrament, they became, as they now are in Catholic countries, wholly impossible: the only dissolution of marriage being in cases where it is void ab initio. In most Protestant countries, the facility of divorce has been so much restored in latter times as to approximate to the heathen practice. In England divorce *a vinculo matrimonii*, on the ground of adultery, can only be obtained by act of parliament; divorce *a mensâ et toro*, commonly termed separation, by sentence of the spiritual court. *See* Marriage, Law of.

DO. In Music, a syllable used by the Italians instead of *ut*, than which it is by them considered more musical and resonant.

DOCE'TÆ. (Gr. δοκειν, *to seem.*) One of the earliest heretical sects; so called from the reality of our Lord's incarnation, and considering him to have acted and suffered only in appearance. Some divines have conceived that the express declarations of the nature of Christ in St. John's writings were specially directed against these opinions.

DO'CIMA'STIC ART. (Gr. δοκιμαζω, *I prove.*) The art of assaying minerals or ores, with a view of determining the quantity of metal which they contain.

DOCK. (Probably from the Gr. δεχομαι, *I receive.*) An artificial basin for the reception of ships. Docks are of two sorts, wet and dry: the former are used for the purpose of loading and unloading a ship's cargo out of the influence of the tide, and are constructed with gates, which when shut keep the ship constantly afloat at low water; the latter are intended for the building, repairing, or examination of ships, which are admitted into them at flood tide, and are so called because they are either left *dry* by the ebbing of the sea, or rendered so by the use of great flood gates or of pumps. The reader will find in the *Commercial Dictionary* a full account of all the docks of Great Britain, with remarks on their utility, history, &c. A *naval dock* is a place provided with all sorts of naval stores, timber, and all the requisite machinery for ship-building. The principal naval docks of Great Britain are Portsmouth, Plymouth, Chatham, Sheerness, Woolwich, and Deptford. It is in these docks, and particularly the three first, that ships of war are laid up in time of peace.

DOCKET, DOCQUET, or DOGGETT (Lat. documentum), in Law, is an abridged entry of an instrument or proceeding on a small piece of paper or parchment. Exemplifications of decrees in chancery, fiats in bankruptcy, and other instruments, are thus *docketed* for purposes of reference.

DO'CTOR, or TEACHER. This title of learned distinction was first adopted in the twelfth century. The degree of Doctorate, succeeding and superior to that of Master in European universities, was first conferred at Bologna; by the university of Paris, in 1145, on Peter Lombard; in England, it is supposed, in the reign of King John. Before this time, if the appellation of Doctor was used, it was only in its plain sense of "teacher," and as synonymous with master. The degree of Doctor is conferred, in the English universities, in each of the three faculties of divinity, law, and medicine, — but not in that of arts, — and in the science of music. The Continental degree of Doctor of Philosophy is unknown among us.

Do'ctor. A thin plate of steel used in scraping the colour or mordant off the copper plates employed in calico printing; the term is probably a corruption of the word *abductor*.

DO'CTORS' COMMONS, is the popular name for the courts and offices occupied by the body incorporated in 1768 under the title of "The College of Doctors of Law exercent in the Ecclesiastical and Admiralty Courts," and which are situate on the southern side of St. Paul's Churchyard. The college consists of a president (the dean of the arches for the time being), and of those doctors of law who having regularly taken that degree in either of the universities of Oxford or Cambridge, and having been admitted advocates in pursuance of the rescript of the Archbishop of Canterbury, have been elected fellows of the college in the manner prescribed by the charter. *See* Courts, Ecclesiastical.

DO'CTRINAIRES. In Politics, a cant word, originally applied in France to a section of politicians who occupied a place, in the first chambers after the restoration of 1815, between the deputies of the centre, who generally supported ministers, and the extreme left, which always opposed them. The chief men of this party were systematic writers and speakers on government, who sought to establish a frame of constitution somewhat more resembling that of England than any which has hitherto subsisted in France. The nickname given to them implied that they were considered by the public as theorists: they were, in fact, the same class which Napoleon used to term Ideologists. They supported the Duc de Cazes when in office; afterwards they were generally in opposition until 1830, since which time several of their leaders have held office at different times. Royer Collard, De Broglie, the young Baron de Stael, Guizot, &c., were among the chief public men commonly called Doctrinaires; but this, like other party nicknames, has been, and is, employed in a very arbitrary manner.

DO'CTRINE (Lat. doceo, *I teach*), signifies, in its most extended sense, any thing that is taught either as a matter of faith or practice; and accordingly the term is applied more particularly to various theories that have been embraced and enforced in philosophy and religion: hence we hear of St. Augustine's *doctrine* of grace, Newton's *doctrine* of colours, &c.

DO'CUMENTS. (Lat. doceo, *I teach.*) In Law, written instruments adduced for the purpose of evidence. *See* Evidence.

DO'DECADA'CTYLUS. (Gr. δωδεκα, *twelve*, and δακτυλος, *a finger.*) The portion of the small intestines called *duodenum*, its length being about the breadth of twelve fingers: this at least may be the case in some animals to which the dissection of the earlier anatomists, who gave this name, was limited.

DODE'CAGON. (Gr. δωδεκα, and γωνια, *an angle.*) A regular polygon of 12 equal sides. If the side of a dodecagon be represented by 1, the area is $=3 \times (2 + \sqrt{3})$ $= 11{\cdot}196$ nearly. In general, the area of the figure is equal to the square of its side multiplied by the constant number 11·196.

DO'DECAHE'DRON. (Gr. δωδεκα, and ἑδρα, *seat.*) One of the five Platonic bodies or regular solids; its surface being composed of 12 equal and regular pentagons. The surface of a dodecahedron is found by multiplying the square of its side or linear edge into the number 20·64578; and its solidity by multiplying the cube of its side by 7·66312.

DODECA'NDROUS. (Gr. δωδεκα, and ανηρ, *a male.*) Any plant having twelve stamens.

DODECA'STYLE. (Gr. δωδεκα, and στυλος, *a column.*) In Architecture, a building having twelve columns on a front or flank.

DODO'NA. In Antiquity, the seat of the most ancient, and one of the most celebrated oracles of Greece, sacred to Jupiter. By some writers its origin is attributed to Deucalion, who is said to have built the town of Dodona where it stood; but according to the traditions of the priestesses of the temple, it was founded by a dove, which, perching on the branch of an oak, recommended in a human voice that a temple should be erected to Jupiter in that place. The situation of the oracle was in an extensive forest, the oaks of which are said to have been endowed with the gift of prophecy; and the oracles were most frequently delivered by three priestesses, who expounded the will of the divinity. That the responses of this oracle were received with singular veneration, may be inferred from the number of votaries by whom it was frequented, and the costly presents which adorned the temple and its precincts. This oracle continued to utter responses till the time of Augustus, when it ceased. (*Strabo*, vii.) *See* Oracle.

DO'DRANS. (Lat.) A measure equal to about nine inches, being the space between the end of the thumb and of the little finger when both are fully extended. It is about equal to the *palm*.

DOG. *See* Canis.

DO'G BELTS. A term used in some coal mines for a strong broad piece of leather round the waist, to which a chain is attached, passing between the legs of the men drawing the dans in the low works.

DOG DAYS. *See* Canicular Days.

DOGE. (Probably a corruption of the Lat. dux, *a leader.*) The title of the supreme executive magistrate in the republic of Venice. The origin of this office dates as far back as 697; when, owing partly to the dissensions and intrigues that resulted from the annual election of the seven tribunes by whom the affairs of Venice had been previously administered, and partly to so divided an authority being found inadequate to the conduct of the rapidly increasing powers of the state, the Venetians resolved to replace the tribunes by a single chief magistrate, who should hold office for life. This magistrate, whom they called *the Doge*, was clothed with almost regal authority. In him was vested the power of convoking assemblies, of declaring war or concluding treaties; of commanding the armies of the state; of appointing the military tribunes and the judges; of hearing appeals and deciding definitively on all matters at issue; of collecting the citizens in their different islands, and in the quarters or districts of Venice, for the purpose of choosing their parish priests or bishops; of judging all matters concerning the clergy in all causes, both civil and criminal; and of awarding ecclesiastical punishments, investing the bishops, and installing them in their churches. (*And. Dandolo apud Gallicioli. Chron.* i.) But notwithstanding these apparently vast powers which were vested in the doge at the first institution of the office, the slightest glance at the history of Venice, which for more than eleven centuries, with a few interruptions, continued to be governed by doges, will abundantly prove that though the Venetians allowed four centuries to elapse before they attempted to fix the bounds or control the exercise of the sovereign authority by any legal enactments, they never ceased to regard with jealousy the chief magistrate of their own appointment and approval, and at last succeeded in limiting and restricting his power, so as to render him a mere state pageant of the *grand* council, in which resided the supreme executive authority. The history of the doges is so incorporated with that of the Venetian republic as to be wholly inseparable from it; and a bare outline of the various phases which they exhibited during a career unrivalled for duration and brilliancy in the annals of human society, would be incompatible at once with our limits and the design of this work. The reader will find ample information on this subject in *Daru's Histoire de la République de Venise* (8 vols. 8vo. Paris); the *Quarterly Review*, vol. 31.; and *Edinburgh Review*, vol. 46. (*See* Bucentaur.) *Doge* was also the title given to the chief magistrates of Genoa, who were elected from the senatorial body. The doges of Genoa held office originally for life, as at Venice; but from 1528 down to 1797, when that form of government was abolished by the French, they remained in office only two years, and their authority was exceedingly circumscribed.

DO'GMA. (Gr. δοκειν, *to seem.*) Literally a conclusion founded upon experience. In Theology, *dogma* has been defined to be a fundamental article of belief derived from acknowledged authority, and is usually applied to what are considered as the essential doctrines of Christianity, deduced either from the Scriptures or from the fathers of the church. (*See* Theology.) There are, however, many other *dogmas* peculiar to the different sects into which Christianity is divided. Thus the bulls and decretals of the pope, together with all the councils both of earlier and later times, are regarded by the Roman Catholics with as much veneration as the authority of the Scriptures and the holy fathers. The Greek church, on the other hand, acknowledges the authority only of the earlier councils, in addition to that of the Scriptures and the fathers; and the Lutheran and other Protestant churches have embodied their dogmas in their respective confessions of faith and other ecclesiastical standards. *Dogmatic theology*, as this branch of divinity is called, in contradistinction to moral and scholastic theology, forms an important object of study in many of the Continental universities. In the Protestant universities of Germany, there are chairs set apart for the history of *dogmas*, or, as it is termed, *Dogmatik*; in which the origin and nature of the dogmas of the various Christian sects are examined, and the merit of the arguments by which they are supported respectively canvassed. Among the ancient physicians, the *dogmatists* founded their practice upon conclusions or opinions drawn from certain theoretical inferences, which they conceived might be logically defended or proved. At present a dogmatist is one who is fond of strong assertions not always founded upon correct reasoning.

DO'G STAR. A name popularly given to *Sirius*, a star of the first magnitude, in the constellation *Canis Major* (the Greater Dog), and the brightest fixed star in the firmament.

DO'GWOOD. A name applied to two different plants: in England to any of the shrubby species of *Cornus*; in the West Indies to the *Piscidia erythrina*. The former are of little interest, except as ornamental shrubs; the latter is a powerful narcotic, the real value of which in medicine has still to be determined.

DOLA'BRIFORM. (Lat. dolabra, *a hatchet.*) In Zoology, when a whole or part is shaped like a hatchet, as the foot of certain Bivalves.

DO'LCE. (It.) In Music, an instruction to the performer that the music is to be executed softly and sweetly.

DO'LERITE. A trap-rock composed of augite and felspar.

DOLICHO'TIS. (Gr. δολιχος, *long*, and ους, *an ear.*) The name applied by F. Cuvier to the subgenus of Cavies, to which the Patagonian hare (*Cavia Patachon.*) belongs.

DOLLAR. *See* Money.

DO'LOMITE. Magnesian marble, or granular magnesian carbonate of lime. Named after Dolomieu.

DO'LPHIN. This term is applied, in common language, to two inhabitants of the ocean of widely different habits and organization: by naturalists it is generally used to signify the dolphin of the ancients, which is a cetaceous mammal of the genus *Delphis* of Linnæus; by poets it is applied to the coryphene (*Coryphæna Hippurus*, Linn.), a fish long celebrated for the swiftness of its swimming, and the brilliant and beautiful colours which it successively assumes in the act of death.

DOM (Lat. dominus, *a lord*), in the middle ages, was a title originally possessed by the pope, and at a somewhat later period by the dignitaries of the Roman Catholic church. In more recent times, it formed a distinguishing title of certain monastic orders, such as the Benedictines, &c.; and it appears to have been equivalent to the *don* of the Spaniards, the *von* of the Germans, and the *de* of the French. Mabillon and Calmet are always spoken of as Dom Mabillon and Dom Calmet.

DOMAI'N (Lat. dominicum, from dominus, *lord*; in legal language, *demesne*), signifies properly that portion of the territorial possessions of a lord which he retains in his own occupation. Thus, the lands retained in possession of the crown, and not granted out to the great feudal lords, were styled domaines in France. *Ancient demesne*, in English law, is a peculiar tenure by which certain lands are held of the crown, being such as are evidenced by Domesday Book to have been in the possession of King Edward the Confessor.

DOME. (Lat. domus.) In Architecture, the spherical or other figured concave ceiling over a circular or polygonal building. A *surbased* or *diminished dome* is one that is segmental on its section; a *surmounted dome* is one that is higher than the radius of its base. The forms of domes are various, both in plan and section. In the former, they are circular and polygonal; in the latter, we find them semicircular, semi-elliptical, segmental, pointed, sometimes in curves of contrary flexure, bell-shaped, &c. The oldest cupola on record is that of the Pantheon at Rome, which was erected under Augustus, and is still perfect. We here subjoin a list of the domes whose dimensions entitle them to notice.

Domes.	Feet diam.	Feet high.
Pantheon at Rome - - -	142	143
Duomo at Florence, Sta. Maria del Fiore - - - - -	139	310
St. Peter's at Rome - - -	139	330
St. Sophia at Constantinople - -	115	201
Baths of Caracalla (Ancient) - -	112	116
St. Paul's, London - - -	112	215
Dome of the Mosque of Achmet -	92	120
Chapel of the Medici - - -	91	199
Baptistery at Florence - - -	86	110
Church of the Invalids at Paris - -	80	173
Minerva Medica at Rome - -	78	97
Madonna della Salute, Venice - -	70	133
St. Geneviéve at Paris (Pantheon) -	67	190
Duomo at Sienna - - -	57	148
Duomo at Milan - - - -	57	254
St. Vitalis at Ravenna - - -	55	91
Val de Grace at Paris - - -	55	133
St. Mark, Venice - - - - -	44	

DO'MESDAY BOOK (*Liber Judiciarius*, or *Censualis Angliæ*), according to Hume, the most valuable piece of antiquity possessed by any nation, was framed by order of William the Conqueror (1031-6), and contains a general survey of most of the lands in England, their extent in each district, their proprietors, tenures, value; the quantity of meadow, pasture, wood, and arable land which they contained; and, in some counties, the number of tenants, cottagers, and slaves of all denominations who lived upon them. It consists of two volumes; one in fol., the other in 4to.: the former comprehending 31 counties, the latter those only of Essex, Norfolk, and Suffolk. The counties of Northumberland, Cumberland, Westmoreland, and Durham, were not comprehended in this survey, probably on account of their then wild uncultivated state. Nor does Lancashire appear under its proper name; but Furness and the north-

ern part of that county, as well as the south of Westmoreland and part of Cumberland, are included within the West Riding of Yorkshire. Though in several respects the information contained in Domesday Book is inaccurate and defective, still in a variety of interesting particulars it serves admirably to illustrate the ancient state of England. The publication of Domesday Book was undertaken by order of Geo. III. in 1767, and was completed, under the superintendence of Mr. Abraham Farley, in 1783. The original is deposited in the Chapter House at Westminster, where it is open to inspection. Sir H. Ellis has published a useful introduction and index to it. Two volumes of Records supplementary to Domesday Book, framed for a similar purpose, and of a nearly contemporary date, were published in 1816 by the Commissioners upon the Public Records. The term Domesday is of doubtful origin: the first syllable seems derived from doom, *judgment*.

DO'MICILE. In Law, the place where a person has his home. Personal property, on the decease of the owner, is distributable according to the law of the country in which he was domiciled at the time of his death; not according to the law of the country in which the property is situate. Residence for forty days constitutes a domicile as to jurisdiction in Scotland.

DOMI'NICAL LETTER. For the purpose of exhibiting the day of the week corresponding to any given day of the year, the framers of the ecclesiastical calendar denoted the seven days of the week by the first seven letters of the alphabet, A, B, C, D, E, F, and G; and placed these letters in a column opposite to the days of the year, in such a manner that A stood opposite the 1st of January or first day of the year, B opposite the 2d, and so on to G, which stood opposite the 7th; after which A returns to the 8th, and so on through the 365 days of the year. Now if one of the days of the week, Sunday, for example, falls opposite to E, Monday will be opposite F, Tuesday G, Wednesday A, and so on; and every Sunday through the year will be represented by the same letter E, every Monday by F, and so on. The letter which represents Sunday is called the *Dominical Letter*, or *Sunday Letter*. As the number of days in the week and the number in the year are prime to each other, two successive years cannot begin with the same day; hence the Dominical Letter changes every year. This mode of representing the days of the week has now fallen nearly into desuetude, and the initial letter of the name of the day is placed in our almanacs opposite the day of the month.

DOMI'NICANS. Friars of the order of St. Dominic, instituted at the beginning of the 13th century. *See* art. ORDERS, MENDICANT.

DO'MINO. (Ital.) A long loose cloak of black silk, furnished with a hood removeable at pleasure, and worn chiefly at masquerades by persons of both sexes by way of general disguise. *See* MASQUERADE.

DON. (Lat. dominus.) A Spanish and Portuguese title, which the king, the princes of the blood, and the highest class of the nobility prefix to their names. The ladies of rank have the predicate donna. The title was originally equivalent to that of knight.

DO'NATISTS. A religious faction, which arose in Africa in the beginning of the 4th century in opposition to Cecilianus, bishop of Carthage. The Numidian bishops were indignant at a slight received from him at the time of his consecration, and declared him informally appointed, on account of their absence from the ceremony. They also accused him of unworthy conduct during the Diocletian persecution. There are two persons of the name of Donatus celebrated as leaders of this party. Their cause was heard before several councils (those of Arles, Milan, and Carthage), in all of which they were pronounced schismatics. The Donatists, however, continued to be a powerful faction for more than 100 years, and raised at various times great wars and commotions. The name of Circumcelliones was given to the numerous bands of country people of the lowest ranks who took up arms in their cause. St. Augustin was most successful in bringing public opinion to bear against the Donatists.

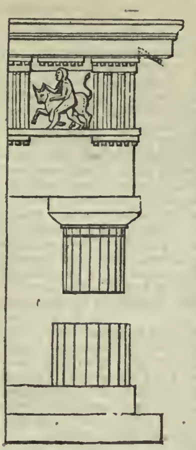
DO'NATIVE, in Law, is a benefice merely given and collated by the patron, without presentation or induction.

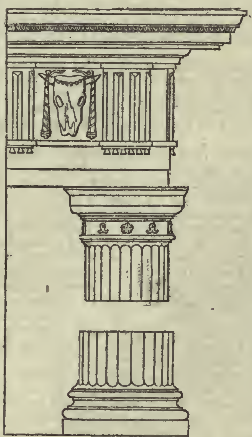
DO'NJON, or DUNGEON. Originally a fortress on a hill: from the Celtic dun, *height*. The central building or keep of an ancient castle; frequently raised on an artificial elevation.

DOOR (Sax. ðoꞃ, Gr. θυρα.) In Architecture, the gate or entrance of a house. The *door frame* is the surrounding case into and out whereof the door shuts and opens. It consists of two upright side pieces or posts and a head, generally fixed together by mortices and tenons, and wrought, rebated, and beaded.

DORA'DO. (Span. *gilt*.) A southern constellation, formed by Bayer; called also sometimes the Sword-fish.

DO'RIC ORDER. In Architecture, one of the five orders. The true origin and birthplace of this order is not satisfactorily known. The example here given is from the temple of Theseus at Athens. The principal points in which the Grecian differs from the Roman Doric are, that it stands at once on the pavement of the building, without socle, tori, or fillets; and that it presents a more pyramidal section than the other, from the great diminution given to it. Its flutes too are never deeply sunk; the capital has no astragal, but only some small annulets to separate it from the shaft. The entablature is so subdivided that the architrave and frieze are each more than a third of its height, the remainder being given to the cornice, which has a band under the mutulus. The mutulus projects forward under the corona, over which is generally placed an ovolo fillet, with another larger ovolo and fillet thereover. The column is usually five or six diameters high. The principal examples of the order are in the Parthenon, temple of Theseus, Propylæum, portico of the Agora at Athens, the temple of Minerva at Sunium, one at Corinth, temple of Apollo and portico of Philip in the Isle of Delos, &c. &c. The Roman Doric varies considerably from that above described. From the diagram it will be seen that the triglyphs are always placed over the centre of the column, and the metopæ should always be an exact square. It follows thence that the intercolumniations are always regulated by the triglyphs. Sometimes it is placed on a plinth, at other times on a pedestal sparingly decorated with mouldings. Though it occasionally, as in this example, has an Attic base, it is more commonly used with only a torus and astragal. The capital is formed with a neck and astragal under the ovolo, and a cymareversa and fillet on the abacus. The only pure ancient example of this order is that of the theatre of Marcellus at Rome. The flutes are without fillets between them, as in the Grecian Doric, and are twenty in number. Of the moderns, by far the most successful in his profile of the order, which they have made what may be called Italian Doric, is Palladio, from whom the example here given is selected.





DORI'PPE. A genus of the short-tailed Decapod Crustaceans, belonging to the tribe *Notopoda*. The species of this genus exist at great depths in the sea, and it is probable that they use the small feet, which are directed towards the back, to cover themselves with foreign bodies for concealment: they have been found in the Mediterranean, Adriatic, and Indian seas.

DO'RMER. (Lat. dormio, *I sleep*.) In Architecture, a window placed on the inclined plane of the roof of a house, whose frame is placed vertically on the rafters.

DO'RMITORY. (Lat. dormio, *I sleep*.) In Architecture, a large sleeping apartment capable of containing many beds.

DO'RNOCK. A stout figured linen, named after the town in Scotland where it was originally manufactured.

DORSIBRA'NCHIATES, *Dorsibranchiata*. (Lat. dorsum, *back*; branchiæ, *gills*.) A name given by Cuvier to an order of Anellidans, or red-blooded worms, comprehending those which have the gills projecting from the middle part of the back or sides of the body. The Nereis, or sea-centipede, is an example of this order.

DORT, SYNOD OF. An assembly of Protestant divines convoked at Dort in 1618-19, by the States-general, under the influence of Maurice, Prince of Nassau, in which the tenets of the Arminians on the five points

relating to election, redemption, original sin, effectual grace, and perseverance, were condemned by the adherents of Calvinism. This national synod consisted of thirty-eight Dutch and Walloon divines, five professors from different universities, and twenty-one lay elders; but besides these there were ecclesiastical deputies present from most of the states of the United Provinces, and from the churches of the Palatinate, Hesse, Switzerland, Bremen, England, and Scotland. This synod was opened on Nov. 13. 1618, and continued till May 29th in the following year, during which period it held 180 sessions; but long before these sessions had come to a close, the Arminians were pronounced guilty of pestilential errors, and condemned as corruptors of the true religion. For minute details of the proceedings of this celebrated synod, the reader may consult *Brandt's History of the Reformation in and about the Low Countries* (London, 1720-22), and the usual authorities in ecclesiastical affairs. It was at this synod that the project of obtaining a translation of the Bible into Dutch was first started. The execution of this task was entrusted to some of the most learned men of the time; and after the lapse of 19 years their labours were given to the world in what has been since known as the *Dort Bible*. (See *Townley's Illustrations of Biblical Literature*.)

DOSI'THEANS. The name of a religious sect which sprung up in the first century of the Christian era. Their principal tenets consisted in believing in the divine mission of their leader, Dositheus, from whom they derived their name, and in rejecting the authority of the prophets by denying their inspiration. This sect remained in existence till the 4th century; but with regard to its history, there exists but little authentic information.

DOTTREL. *See* Numerius.

DOU'BLE BASS. *See* Contrabasso.

DOU'BLE STARS. *See* Stars, Double.

DOUBLOO'N. *See* Money.

DOUCHE. (Fr.) A jet or current of water directed upon some part of the body. An apparatus for this purpose is to be found in most bathing establishments. Steam or vapour is also sometimes applied in the form of douche.

DO'VECOT. A structure for keeping tame pigeons; the only essential difference between which and a common poultry-house is, that the entrance for the birds must be raised to a considerable height from the ground, because pigeons fly higher in the atmosphere than most other birds.

DO'VER'S POWDER. A compound of ipecacuanha, opium, and sulphate of potash. It is the *pulvis ipecacuanhæ compositus*, or compound powder of ipecacuanha of the present Pharmacopœia. Ten grains, which is the average dose, contain one grain of opium and one of ipecacuanha. It is an excellent sedative and sudorific.

DO'VE-TAIL. (From its spreading like a pigeon's tail.) In Architecture, a joint used by carpenters in connecting two pieces of wood by letting one piece into the other, in the form of the expanded tail of a dove. It is the strongest method of joining masses, because the tenon or piece of wood widens as it extends, so that it cannot be drawn out, because the tongue is larger than the cavity through which it would have to be drawn. The French call this method *queue d'hironde*, or swallow's tail.

DOW'AGER (Fr. douairière), seems to signify a widow who either enjoys a dower from her deceased husband, or who has property of her own brought by her to her husband on marriage (dowry), and settled on herself after his decease. In the language of etiquette the term is applied to a widow lady, to distinguish her from the wife of her husband's heir having the same title.

DOW'ER (Lat. dotarium, from dos), in Law, is defined to be the estate for life a widow acquires in a certain portion of her husband's real property after his death. Dower by the common law entitles her to a third part of all the lands and tenements of which the husband was seised in fee-simple or fee-tail at any time during the coverture. Hence this species of dower could not be affected by the husband's conveyance of the lands, unless by fine or recovery in which the wife joined, or by his devise. But the law in this respect has undergone material alterations by the provisions of the 3 & 4 W. 4. c. 105. Dower by custom varies in different districts. There were other obsolete species of dower, now abolished by the statute already mentioned. A married woman may be deprived of her right to dower by attainder of her husband for treason, or herself for treason and felony; by divorce a vinculo matrimonii; by elopement from the husband and living with an adulterer, which incapacity may be removed by reconciliation with the husband. In order to prevent the inconveniences occasioned by this right, which materially impeded the conveyance of property, various modes of *barring*, i.e. defeating, the right to dower were invented by legal ingenuity. Of these the most usual in practice was and still is the limitation of a separate estate (commonly, although incorrectly, called a jointure) to the wife on marriage. This estate must be "a competent livelihood of freehold for the wife, of lands and tenements, to take effect in profit or possession presently after the death of the husband, for the life of the wife at least." This mode of barring dower derives its efficacy from the provisions of the Statute of Uses, 27 H. 8. c. 10. But now by 3 & 4 W. 4. c. 105. dower may be barred by a simple declaration in the deed by which land is conveyed to the husband, or in any deed executed by him; or by declaration in his will, or by any devise of real estate to her.

DOWLAS. A coarse kind of linen.

DOWNS, have been defined to be banks or elevations of sand which the sea gathers and forms along its shores, and which serve it as a barrier. The word is derived from the Celtic *dune*, which see. The term is also applied to large tracts of poor naked hilly land which serve chiefly for the grazing of sheep, thence called Down sheep. Downs is the name given to the well-known road for shipping in the English Channel, which possesses excellent anchorage, and in time of war forms the place of rendezvous for the English navy.

DOW'RY, although often confounded with *dower*, has a different meaning; namely, the *dos mulieris* or marriage portion brought by the wife to her husband. The word, however, has no legal signification.

DOXO'LOGY. (Gr. δοξα, *glory*; λογος, *discourse*.) A form of praise or glorification. The greater and lesser Doxologies, as they are distinguished by the liturgical writers, are the hymn sung by the angels at the Nativity, "Glory be to God on high," &c.; and the shorter form, "Glory be to the Father," &c. The last clause in the Lord's Prayer, as it is recorded by St. Matthew, the genuineness of which has been sometimes questioned, is also frequently called the Doxology.

DRACHM. There are two drachms in our system of weights; namely, the avoirdupois drachm, which is the sixteenth part of the avoirdupois ounce; and the apothecaries' drachm, which is the twelfth part of the troy ounce, and equivalent to sixty troy grains: the latter drachm is the only one which is retained in common use.

DRA'CHMA. (Gr. δραχμή.) An Athenian silver coin of the value of six oboli, or about 7¾*d.* of our money. Other Greek states had *drachmæ* of different values, but the above is that generally referred to. There was also a weight of this name nearly equivalent to 2 dwt. 7 gr. troy weight.

DRA'CO. (Lat. *the Dragon*.) One of the ancient constellations in the northern hemisphere.

DRA'CO MITIGA'TUS. An alchemical name of *calomel*: corrosive sublimate was probably called *draco* or the dragon.

DRACO'NIN, or DRACINA. The colouring matter of the resin called *dragon's blood*.

DRA'GOMANS. The interpreters attached to European embassies or consulates in the Levant. The dragoman of the Sublime Porte is an important Turkish officer, who forms the medium of communication between his own government and the embassies of foreign countries.

DRA'GON. (Gr. δρακων.) In Fabulous History, one of the most famous mythological creations of antiquity and the middle ages. The position which this being occupies in fabulous history presents one of the most singular phenomena of the human mind, as its existence was firmly accredited among the ancients of almost every nation, both in the eastern and western regions of the earth. It occurs in the sacred allegories of the Jews, and in the legends of the Chinese and Japanese; and the pages of the classic poets of Greece and Rome teem with representations of the dragon. Thus the dark retreats of their gods and their sacred groves were defended by dragons; the chariot of Ceres was drawn by them; and a dragon kept the garden of the Hesperides. In Scandinavian mysteries, the dragon was the minister of vengeance under their vindictive gods (see *Grimm's Deutsche Mythologie*); and the ancient Britons, enslaved in the trammels of Druidic superstition, entertained a similar notion of its nature. (*Rees's Cyclopædia*.) The allegory of the Dragon has even found a place among many nations who have embraced Christianity. In the the Book of Revelations (chap. 20.), the angel is represented as laying "hold on the dragon, that old serpent, which is the devil;" and hence in painting and statuary the triumph of Christianity over infidelity and heathenism is sometimes represented by a dragon pierced or trampled under foot. This representation forms also the attribute of different saints in the legends of Christianity, more especially of St. Michael, St. George, and St. Margaret the Martyr. The dragon of antiquity was a species of monstrous serpent with wings and feet; and he seems to have possessed many qualities in common with the most famed terrors of ancient Greece, such as the

Gorgons and hydras and chimæras dire,

with which he was in all probability intimately allied.

Dragon. In Zoology, this term is applied to a genus of small Saurian reptiles, characterized by two lateral aliform productions of the skin supported upon the first

six pairs of ribs; which, instead of bending round the thorax, are elongated and directed outwards for that purpose.

DRA'GON BEAM. In Architecture, an horizontal piece of timber on which the hip or angle rafters of a roof pitch. It is framed into a short diagonal piece, which ties the plates at the internal angles of a roof.

DRA'GON FLY. A common name for the Neuropterous insects belonging to the genus *Agrion* or *Lobellula*.

DRAGONNA'DES. (Fr.) The name given to the persecutions instituted by Louis XIV. and his successor against the French Protestants, from the coercive measures (parce qu'on y employait les *dragons*) which were put in force to effect their conversion.

DRA'GON'S BLOOD. A deep red resin used in colouring varnishes; it is the produce of the *Pterocarpus draco*, and is imported from India.

DRAGOO'NS (Fr. dragon; probably from the Lat. draconarius, *the bearer of a standard upon which was represented the figure of a dragon*), is the name given to a species of cavalry trained and armed to act either on foot or on horseback, as emergencies may require. The origin of this species of troops has been ascribed by Pere Daniel to the Marechal de Brissac; but there can be but little doubt that a sort of soldiers answering exactly to the definition above given of dragoons was in use among the ancient Romans. At present dragoons form part of the military force of all the powers of Europe. The first regiment of dragoons in this country was raised in 1681, and called the Royal Regiment of Dragoons of North Britain, now the *Scots Greys*. In England, this species of troops is of two sorts,—*Dragoons* simply, and *Dragoon guards;* the difference between them consisting in this, that the accoutrements and horses of the latter are somewhat heavier than those of the former. *See* CAVALRY.

DRAI'NING. The art of freeing the surface of the soil from superfluous water, considered with reference to cultivated vegetables, and the health of man and animals. Water may become superfluous by being collected in the natural hollows on the surface, and thus forming bogs; by being retained in the surface stratum, in consequence of a retentive subsoil; or by oozing through a moist subsoil to the surface stratum, in consequence of supplies from subterraneous sources. Water collected in bogs, or marshy places, remains there, because it has no natural outlet, neither by an opening or hollow along the natural surface, nor by the porosity of the subsoil, in consequence of which the water might sink into it and disappear. The obvious mode of draining in the first case is by a trench or drain, so deep as to draw the water from the lowest parts of the hollow, bog, or marsh. Where water is retained in the surface soil in consequence of a retentive subsoil, as in the case of clays and many loams, the most effective mode is to cut a number of small drains parallel to and at short distances from one another; and by the tops of these drains reaching within an inch or two of the bottom of the surface soil, which in cultivation is turned over by the plough, they absorb the superfluous water that passes through this soil and carry it off. Or, should the land be in pasture, the tops of the drain should be brought within an inch or two of the grassy surface, so as to intercept the water, both oozing laterally from the surface soil, and vertically from among the leaves of the grass. It may be observed also that pasture lands on this description of retentive soil may be more readily drained when laid into ridges, and an underground drain formed under each furrow or surface drain. This, however, is not essential; and though furrows or surface drains would be no deformity in field culture, yet in lawns and parks the appearance of furrows would destroy the continuity and evenness of surface, which in lawns is one chief source of beauty. To drain the surface soil, where it is supplied by water from the subsoil, requires some knowledge of the strata of which the subsoil is composed. In general the strata composing the subsoil lie over one another in a direction more or less approaching to horizontal; and when the natural inclination of the surface is everywhere parallel to this strata beneath, the water, if it oozes out of the subsoil at all, will generally do so equally throughout the subsoil; and in such cases numerous drains at no great distance are required to carry it off, precisely as in the case of draining soils with retentive subsoils. But when the line of surface does not correspond with the line of substrata, but intersects this line, then water will generally be found oozing out at the line of intersection, technically called the cropping out of the strata. The quantity of water which will issue from these sections or croppings out of broken strata will depend on a great variety of circumstances, into which it is unnecessary here to enter; because in all cases the mode of draining is the same, viz. that of forming a drain parallel to the line of the fracture of the strata. This drain in some cases is not required to extend the whole length of the line of fracture; because if the strata have a double inclination, so as it were to conduct the water to one angle or point, a drain at that angle or point will carry off the whole of the superfluous water contained in the strata. The subsoil in some cases is composed of strata in a nearly vertical position, and in others of strata alternately depressed and elevated, so that a section through them would form a serpentine line; and sometimes the subsoil is composed of strata the layers of which have been broken up and jumbled together. All these, and other cases, are to be drained in one or more of the above described modes; that is, accumulated water, whether in the soil or above it, is to be let off by cuts or drains made at the lowest points of accumulation; and surface soil saturated with water, whether from greater atmospherical supplies than can be carried off by evaporation or can sink into the subsoil, or whether it arise from sources in the subsoil, is to be carried off by numerous drains close to one another, and the tops of which are within a few inches of the cultivated soil, or of the permanent clothing of grass or other herbage.

DRA'MA (from the Greek word δρᾶμα, *an action or thing done;* derived from the verb δραω, *I act or do*), has been defined a species of poem in which the action or narrative is not related, but represented. The invention of the drama is one of those which should seem to proceed most naturally from the ordinary customs and feelings of men. There is a species of dramatic action which seems almost instinctive; we naturally imitate the tone and gestures of others in reciting their sayings or adventures, or even in adopting their sentiments. Yet some nations appear never to have taken the farther step of doing, methodically and with design, what all do involuntarily. In the accounts which we possess of the ancient Egyptians, for example, we have no trace of their having possessed dramatic representation. But among a great number of tribes, wholly independent of each other, we find something approaching to the dramatic art intermingled with their common or solemn customs, and generally connected with religious observance. This was especially the case in Greece, whence the name and substance of the drama have been chiefly derived by the modern European nations.

The history of the development of the dramatic art in Greece is well known: its elements were found in the religious festivals celebrated from the earliest ages in that country. The feasts of Bacchus in particular had sacred choruses or odes; these were afterwards intermixed with episodic narrations of events in mythological story, recited by an actor in the festival with gesticulation: thence again, the next step was to introduce two actors with alternate recitation; and thus were produced tragedy (τραγωδιά, *the song of the goat*, from the animal which was led about in those festive processions); and comedy (κωμωδιά, *the village song*), which differed from the former in that the dialogue of the interlocutors was satirical, and not mythological. The early Greek tragedy was a dramatic representation of some scenes or events recorded in the national traditions, the actors personating those who played a part in these events, together with a chorus or band of singers, representing such persons as might naturally be supposed to have been bystanders at the occurrence (captive women, old men, or counsellors, &c.), who sang at intervals, during the representation, hymns to the gods, or songs appropriate to the scenes passing in representation: while the Attic comedy, in its first invention, must be regarded as a parody on tragedy, in which the personages were either real characters introduced for the purpose of satire, or ludicrous personifications. Æschylus, the oldest tragic writer (with the exception of Phrynichus, his cotemporary), carried the Greek drama at once to nearly its highest state of perfection. Sophocles and Euripides introduced additional actors into the dialogue (which at first admitted only two at the same time), and turned the naked recitals of events which form the substance of the plays of Æschylus into something more nearly resembling the modern idea of a plot, with contrasted characters and incidents leading to the accomplishment of a main action. Many tragic writers, the whole of whose works have been lost, flourished after Euripides in Athens and Alexandria; but they do not seem to have altered the character of the art which they received from their predecessors. The fate of comedy was different: the old Attic comedy was a political or philosophical satire in action, which in form was a burlesque on the tragedy. Afterwards, passing through the intervening stage of the middle comedy, of which we know little, the art acquired in the new comedy of Menander and Philemon a character somewhat approaching to that in which it is at present cultivated; a narrative in representation of scenes and incidents in ordinary life of a light or ludicrous character.

The dramatic art among the Greeks aimed at producing an impression upon the spectators by three different means; which, according to modern phraseology, we may denominate poetical effect, dramatical effect, and theatrical effect. The poetry of the Greek drama was of the highest order; but it forms a topic to be considered apart. Dramatical effect is the proper subject of the dramatic art; and, in judging of the efforts of the Greek mind in this direction, we are assisted not only by the

study of the dramatic poems which we possess, but by the rules of criticism delivered to us by Greek authors, and especially by Aristotle. From these it appears that the parts or characteristics of a tragedy, essentially divided, were held to be the fable or story, the manners, the style, the sentiment, the music, and the diction: that the fable should consist of an entire action, namely, one principal event and the auxiliary events; and that the proper emotions to be excited by the action are terror and pity: that its parts of quantity, according to the division of form, were the prologue, being that part of the tragedy which precedes the parode or first entry of the chorus; the episode, being all those several parts which are included between the several choral odes; the exode, the part which follows the last choral ode; and the chorus itself, or the intervening odes, which also admit of various subdivisions. Formally considered, the arrangement of the old comedy nearly resembled that of tragedy; in the new, the chorus was altogether omitted. The unity of action was a remarkable characteristic of the Greek drama, although widely different from that peculiar quality which modern critics have characterized by the name: it should rather be termed unity of subject, inasmuch as in many of our remaining tragedies, and especially those of Æschylus, there is little or no trace of what we term a plot, *i.e.* a main incident at which we arrive through subordinate incidents tending to its accomplishment. The unity of time, —viz. that the imaginary duration of the action should not exceed twenty-four hours; and that of place,—namely, that the scene in which the events occur should be the same throughout,—are inventions of French critics, not warranted by the remains of Greek art, in which both are not unfrequently violated; but, although not rules of Grecian discovery, they are easily rendered applicable to the simple and severe form of the Greek tragedy.

In considering the theatrical effect of the Greek drama, we must remember that the tragedies were originally religious solemnities; the theatre, a vast building open at the top, calculated for the accommodation of several thousand spectators; the scene, &c. proportionally large. Dramatic representations were, at Athens, the offering of wealthy men to the people: he who contributed the expenses of the entertainment was said, εἰσάγειν, to bring in the play; the poet who produced it, διδάσκειν, to teach it, *i.e.* teach the actors to perform it. A complete representation consisted of four pieces by the same author; a trilogy, or three tragedies, narrating successive events in the same series of mythological tradition; and a fourth piece, termed a satyric drama, of which the chorus consisted of satyrs, and the mythological subject was treated in a manner approaching to burlesque. The features of the actors were exaggerated by masks, their height increased by dress, their powers of voice aided by acoustic contrivances, in order to suit the colossal dimensions of the theatre. The whole vocal part was rhythmical; the choral odes were sung, and accompanied by the choric dance, in which the actors composing the chorus took part, subjected to very peculiar rules: the narrative part of the performance was spoken in a peculiar modulated voice, resembling probably the recitative of the modern opera. As to the metrical character of the ancient Greek drama, the metre used in the dialogue was the iambic trimeter, varied occasionally with the anapæstic and trochaic, chiefly where the other dramatis personæ conversed with the chorus, or the members of the chorus itself took part in the action; the choral odes were composed in a great and very artificial variety of metre.

Latin Drama.—The early Etruscans possessed dramatic representations, whence the Romans derived some peculiar national entertainments (*see* MIMI); but, with this slight exception, their drama consisted merely in the first instance of translations, afterwards of close imitations of the Greek. Accius and Pacuvius transferred to the Roman stage the tragedy of the three Attic poets; Plautus and Terence the new comedy of Menander. Of these writers Terence is the only one who appears to have deviated, and that slightly, into original invention: in the degeneracy of the Roman empire even this adscititious taste ceased to be cultivated, and the theatres were entirely occupied by farcical buffoonery, or shows and sports on a gigantic scale. Among an infinite variety of works which treat of the classical drama, may be cited the first volume of *Schlegel on Dramatic Art and Literature.* A catalogue of them will be found at the end of the 4th edition of the *Theatre of the Greeks*, Cambridge, 1836. See also *Edin. Rev.*, vol. 49.

Chinese Drama.—Before proceeding to the dramatic art of modern Europe, derived as it is from that of Greece, two oriental nations may be noticed which possess a national drama of their own. In China, theatrical entertainments form one of the most popular amusements, and theatrical writing has been cultivated from a very early period. The Chinese drama comprises pieces which we should term both tragical and historical plays, tragicomedies, and comedies both of intrigue and of manners; together with abundance of low, pantomimic, and farcical representations. In their regular drama, however, there appears to be less of what we should term connected than of successive action: many of them are, as it were, dramatized memoirs or biographies of individuals, real or fictitious; the representation of some is said to require ten days. It is remarkable that, of all national dramas, the Chinese appears to be the only one in which we can trace no original connection with religious observance. (*Morrison, Horæ Linicæ; Abel Remusat; Memoirs of the Acad. des Inscriptions*, &c.)

Hindoo Drama.—The Hindoo plays which now exist are written for the most part in Sanscrit, although not a living language at the period when they were composed; mixed, however, with other dialects, which, according to Hindoo critics, are respectively appropriate to different parts of a play. They seem to have been appropriated to the entertainment of learned persons, and acted only on solemn occasions. They are few in number; about sixty only are known: some containing long mythological narratives, others much complicated incident of a domestic character, in a strain of tragedy alternating with comedy, like the romantic drama of modern Europe. The dramatic art appears to have flourished in India during a period of several ages, ending about the 14th or 15th centuries of our era. Dramatic criticism was also much cultivated; and the most minute and artificial rules are laid down by Hindoo commentators as to the conduct of a piece, the requisite ethics, the formal arrangement, and the characters which must be introduced. The Hindoo drama is so widely different from the Greek or Chinese, that it must be regarded, like them, as a spontaneous offspring of national genius. (*Wilson's Specimens of the Theatre of the Hindoos*, 2 vols. 8vo. 1835.)

Modern European Drama.—For many centuries after the downfall of the Roman empire, the dramatic art appears to have been entirely lost. Its first revival in the middle ages was owing to the solemnities of the church, into which dramatic interludes were introduced in various countries of western Europe, representing at first events in biblical history or the lives of the saints, and afterwards intermingled with allegorical fantasies. (*See* MYSTERIES, MORALITIES.) The framers of these early pieces were monks, and the monks were the only preservers of classical learning; but whether we can infer from these facts that the idea of these rude representations was suggested or their details improved by classical associations, it is not easy to pronounce. At the period of the revival of literature, however, the dramatic art was called nearly at once into life in the four principal countries of western Europe; Italy, France, Spain, and England. In the two first of these countries it arose simply classical, and unmixed with any original conceptions, or with the sentiments and fashions of the middle ages; in the two last it partook largely of both, and was also immediately derived from the mysteries and moralities above mentioned: hence, in a historical view, arose the distinction, so elaborately explained by modern critics, between the classical and romantic drama.

Italian Drama.—Originated in close imitation of classical models. The *Sofonisba* of Trissino (1515) is not absolutely the oldest Italian play, but the first which served as a model for subsequent composers. Rucellai and many others followed in the same track; Bibbiena, Machiavel, Ariosto, as closely imitated the model of the Terentian comedy. The pastoral drama of the 16th century, of which Tasso and Guarini were the most celebrated writers, furnished the first novelty in this branch of literature; but these are rather poetical than dramatical compositions. The true national theatre of Italy arose in the 17th century, in the musical drama (opera), to which Metastasio, early in the 18th, communicated all the charms of poetry; but since the period of that writer, the operatic part of the dramatic art has again been wholly disconnected from the literary, and the words only serve as vehicles for the music. While the higher classes were devoted to the opera, the lower found their national amusement in the commedie dell' arte; comedies performed by masqued characters, which gradually became fixed in the well-known persons of Harlequin, Pantaloon, Brighella, &c., who improvised their parts: Goldoni, in the middle of the 18th century, succeeding in establishing a regular comic drama in possession of the stage; while his rival, Gasparo Gozzi, took up the commedie dell' arte as models, and founded upon them a series of amusing extravagances. But since the period of these two spirited writers comedy has fallen almost completely into disrepute. At the end of the 18th century Alfieri, a bold and severe genius, produced tragedies in which the ancient classical form (with the exception of the chorus) was again reverted to, instead of the French imitations of it which had long been current in Italy as well as the rest of Europe; and several dramatic poets have since appeared, who have adopted the same model. (*Ginguené, Litterature Italienne; Tiraboschi; Walker on Italian Tragedy*, 1799; *On the Revival of the Drama in Italy*, 1805; *Riccoloni, Hist. of the Ital. Theatre.*)

French Drama.—The early French tragic writers, from the beginning of the 16th century down to Corneille in the

middle of the 17th, produced nothing but unsuccessful and somewhat barbarous imitations of the Greek tragedy. The first pieces of this kind represented on the French stage had prologues and choruses. Corneille had studied and loved the Spanish drama; and without introducing much of its varied form and incident, he transfused a portion of its boldness and romantic sentiment into the French theatre, together with a power of energetic declamation peculiarly his own. Racine, on the other hand, was a pure admirer of antiquity; but with a taste and delicacy of feeling which until his time had been very rarely found to accompany classical knowledge. The French tragedy grew up with these two great writers as models, and Boileau as its legislator. A peculiar and rigorous system of criticism was introduced, affecting both the form and the substance of dramatic writing; and this system became established in the minds of the French public, as the natural and not the conventional rule of beauty. It would be impossible to enter into an examination of the rules of the French drama; suffice it to say, that they banished from the tragic stage all except heroic characters and passion; required perfect simplicity of plot, uniformity of language, and, in addition, the observance of the before-mentioned technical unities of place and time. These rules have ever since been scrupulously followed, without deviation, on the regular French stage, and many of the greatest names in dramatic literature have voluntarily subjected themselves to their restraints. The French comedy, however, is infinitely more national and characteristic than the French tragedy: it originated in that of Spain, and was carried at once to a high degree of perfection by Molière, — rejecting the extravagance of the Spanish drama, confining itself within certain definite limits governed by analogy to those established for tragedy, and retaining satire instead of adventure as its leading principle. Since that period the French comic stage has been, beyond all contradiction, not only the best, but the model from which that of all other nations has been wholly derived. Of the present state of the French drama it is difficult to speak with precision; but the national or regular stage seems to be every day losing in popularity, while the attempts to establish a new one on what is termed in France the romantic model have hitherto met with very partial success. (*Laharpe, Cours de Littérature; Correspondance de Grimm*, passim; *Voltaire, Discourse on Tragedy; Schlegel.*)

Spanish Drama. — Spain commenced her literary career more independent of foreign aid than any other country. Her dramatic art appears to have originated as early as the 14th century; which produced satirical pieces in dialogue, and one complete dramatic romance by an unknown author (*La Celestina*), in addition to the mysteries and miracle plays, which were exhibited in Spain even more plentifully than elsewhere. The early Spanish comedies of the 16th century were conversations, like eclogues, between shepherds and shepherdesses; with occasional interludes of negroes, clowns, and Biscayans, the favourite subjects of popular jest. But the Spanish drama owed to one great author, Lope de Vega, what our own owed to his contemporary, Shakspeare, — a rise at a single bound from insignificance to great richness and variety; he created, moreover, nearly all its numerous divisions, and has left examples of each. The name comedy, in the early Spanish stage, implied no ludicrous or satirical representation, but simply a play of adventure. Comedias divinas, or spiritual comedies, were subdivided into lives of saints, and pieces of the holy sacrament (autos sacramentales): the comedies of human life into heroic, answering to the tragedy of our early English dramatists, although even less regular in form; and comedies of domestic adventure (comedias de capa y espada, — of cloak and sword). Besides these, the interludes which were played between the prologue and the piece (sayneteres) possess a distinct character as literary compositions. Almost all pieces have one favourite invariable character, the gracioso or buffoon. Calderon, a greater poet than Lope, and his equal in dramatic power, is the only other great name in the Spanish drama. Subsequent writers may all be classed as imitators either of their own older poets, or of the favourite dramatists of the French school. (*Bouterweck's Hist. of Sp. Literature; Quart. Rev.*, vol. 38.; *Sismondi, Lit. du Midi de l'Europe; Schlegel.*)

English Drama. — For the semi-religious representations out of which the English drama arose, *see* Mystery and Morality. One of the latter, *The New Custom*, was printed as late as 1573; by which time several regular tragedies and comedies, tolerably approaching to the classical model, had appeared. But a third species of exhibition soon took possession of the stage, the historical drama, in which the successive events of a particular reign or portion of history were represented on the stage; and, together with it, arose the English tragedy and comedy. Our first dramatic poets (those before Shakspeare) were scholars; hence they preferred the form of the ancient drama, the division into acts, &c. But they were also writers, who strove for popularity with the general class of their countrymen; hence, instead of imitating classical simplicity, and confining themselves to a peculiar cast of diction and sentiment removed from the ordinary course of life, they invented a species of composition which intermingled poetical with ordinary life and language. Comedy, again, became in their hands a representation of adventures, differing from those of tragedy only by ending generally in a happy instead of an unhappy exit, and not materially either in the characters or language. Thus the distinctions which they established between tragedy, comedy, and tragi-comedy, are little more than adventitious; and the Shakspearian drama, properly considered, must be looked on as a miscellaneous compound, in which actors, language, and sentiments, of a character far removed from those of ordinary life, alternate with those of a low and even a burlesque character. There is no tragedy of Shakspeare in which comic scenes and characters are not introduced: there is only one comedy (*The Merry Wives of Windsor*) without some intermixture of sentiment approaching to tragic. It continued to be the chief national literature, as well as the favourite national amusement, down to the period of the civil wars, when the opinions and legislation of the prevailing party put a stop to dramatic representation altogether. During the interval thus created the old English art was unlearned altogether, and the new drama, on the model of the French, introduced almost at once on the return of Charles II. and his courtiers from the Continent. The distinction between tragedy and comedy was then first substantially recognized: the former confined to heroic events and language, the latter to those of ordinary life. But tragedy, subjected to foreign rules, ceased entirely to flourish: and Otway, the last writer of the old English drama, who wrote partly on the ancient model, although after the Restoration, is also the last tragic poet of England who still occupies the stage; with the exception of Rowe, and of a few authors of that peculiar species of composition, the domestic tragedy, in which the distresses and melancholy events of common life are substituted for those of an heroic character. Comedy, on the other hand, obtained possession of the national taste and stage; and although the charm of poetry and romantic adventure, which had belonged to the old drama under either name, was denied to the modern comedy, it soon attained a high degree of excellence as well as popularity. The last comedies in verse were written shortly after the Restoration; since which time, with the exception of a few insulated attempts to revive the older form, it has been entirely framed on the French model. The main element of a modern comedy is satire; but it admits of a subdivision into comedy of intrigue and comedy of manners, — the former being chiefly directed to the development of a plot, the latter to the delineation of manners; although these qualities ought, properly speaking, to be united to constitute a good play. The most distinguished of our dramatic writers in the former line are, amongst many, Congreve, Vanbrugh, Farquhar, Colman, Sheridan: in the latter, the writings of Shadwell and Foote, perhaps, afford the most remarkable instances of that less popular form of comedy which almost neglects the interest of plot, and confines itself to a satirical representation of prevailing vices and follies. (See *Edin. Rev.* vol. 38.; *Prolegomena to Malone and Boswell's Shakspeare; Hazlitt's Lectures; Coleridge's Remains; Collier, Hist. of Eng. Dramatic Poetry.*)

German Drama. — The modern German drama is founded on the old English model; and, although the last in order of time, has risen to a high degree of excellence, the stage in Germany being incomparably more national and popular at the present time than in other European countries. While France, England, and Spain have to look back two hundred years for those names which form the glory of their dramatic literature, Lessing, Schiller, and Goethe are writers only of the past generation.

DRAMATU'RGY. (Gr. δϱαμα, and εϱγον, *work.*) The science or art of dramatic poetry and representation: a word used by German writers.

DRAM TIMBER. *See* Baulk.

DRA'PERY. (Fr. draperie.) In Painting and Sculpture, the clothing applied to the human figure. *See* Casting of Drapery.

DRA'STIC MEDICINES. (Gr. δϱαστικος, *effective.*) A term chiefly applied to purgatives and some other remedies which are rapid and powerful in their operation.

DRAUGHT OF WATER. The depth of the lowest point of the ship: as the keel is seldom exactly horizontal, the draught of water is taken forward and aft. A ship of the largest size draws nearly 30 feet.

DRAW'BACK. In Political Economy. When a duty is laid on an article produced in a country that is suitable for the foreign market, it is usual, on its being entered for exportation, to remit or pay back the duty to the exporter; and hence the technical phrase drawback. The policy of a measure of this sort is, in most cases, obvious. It is rarely for the public advantage to impose a duty on an article about to be exported; the inevitable effect of such duty is, by proportionally increasing the price of the article, to lessen the foreign

demand for it; and its probable effect is, in most instances, entirely to exclude it from the foreign markets. Except in a few rare cases, one country has seldom so great an advantage over others in the production of commodities as would justify the imposition of a duty on their exportation, without incurring an extreme risk of making them be supplied from some other quarter. This, however, is a result to be deprecated in every point of view. And hence in every case in which the exporting country has no ascertained or decided superiority over others in the production of commodities on which duties are laid at home, there can be no question as to the expediency of drawbacks. These must not, however, exceed the amount of duty charged; for when they do this, the excess becomes, in fact, a bounty.

DRAW′ING. (Sax. ðraᵹan, *to draw along.*) In the Fine Arts, the art of representing any object by means of lines circumscribing its boundaries. Drawing is of course the foundation of every thing in art, including within it a knowledge of perspective, anatomy, and proportion, and when acquired giving, as Sir Joshua Reynolds observes, "a proportionable power of drawing correctly what we imagine." The human figure is the principal, perhaps the only object, upon which a student should be first employed; for he who can correctly draw that will not be at a loss in representing any thing else he may wish. Sir Joshua observes, that he who endeavours to copy nicely the figure before him, not only acquires a "habit of exactness and precision, but is continually advancing in his knowledge of the human figure; and though he seems to superficial observers to make a slower progress, he will be found at last capable of adding (without running into capricious wildness) that grace and beauty which is necessary to be given to his more finished works, and which cannot be got by the moderns, as it was not acquired by the ancients, but by an attentive and well compared study of the human form."

DREAMS (Germ. Träume), may be defined to be those trains of ideas which occupy the mind, or those imaginary transactions in which it is engaged, during sleep. Dreams constitute some of the most curious phenomena of the human mind, and have in all ages presented to philosophers a subject of most interesting investigation. The theory of dreams embraces two distinct classes of phenomena, *physical* and *psychological*: the former relate to the question as to how the body is affected in a state of sleep (*see* Sleep), how the body in that state affects the mind, and how this affection operates to the production of the phenomena of dreams; the latter comprehend an inquiry into the laws which regulate the train of ideas that occur during sleep, and the mode in which these laws operate, together with an examination of certain psychological appearances peculiar to that state. To both these classes of phenomena the attention of some of the most distinguished philosophers, both of antiquity and of modern times, has been directed; and much labour and ingenuity have been expended in endeavouring to ascertain the origin and nature of dreams, and to account for the various phenomena by which they are accompanied. To give even an outline of the various theories that have been propounded on this subject, would be wholly incompatible with our limits. The system of condensation on which works of this species must be constructed is, as will be easily understood, but little suited for metaphysical disquisitions, in which, to use a remark of Horace, brevity so easily degenerates into obscurity; but in the present instance this is perhaps the less to be regretted, for of all those speculative questions which are said to lie beyond the reach of human inquiry, there is none on which the opinions of philosophers are more conflicting and unsatisfactory than the theory of dreams. Among a multitude of other *efficient* causes, dreams have been ascribed to direct impressions on the organs of sense during sleep, — to the absence of real impressions on the senses, — to a disordered state of the digestive organs, — to a less restrained action of the mental faculties, — to the suspension of volition while the powers of sensation continue, — and to the succession and unequal relaxation and cessation of the different senses at the commencement and during the time of sleep. (*Encyc. Edin.*) From the remotest period of antiquity, dreams have also been ascribed to supernatural agency. The records of history, both sacred and profane, abound in instances of dreams which it is impossible to account for on any other hypothesis than that of a supernatural interposition; and, as has been well observed, though there can be no doubt that many dreams which have been considered supernatural, as revealing facts and scientific truths, may now be explained by means within our own knowledge, it can just as little be doubted that many well authenticated dreams are utterly inexplicable by ordinary or natural means. This belief in the supernatural character of dreams is common to every nation in a greater or less degree; but it prevails more especially in the countries of the East, where, from time immemorial, there has existed a class of persons whose peculiar occupation consists in the interpretation and explanation of dreams. Those who wish for comprehensive details on this subject may consult the writings of Aristotle, Lucretius, Democritus, &c.; and, among ourselves, of Locke, Newton, Hartley, Baxter, Beattie, and Stewart; and still more recently, those of Abercrombie and Macnish, which are extremely valuable for the numerous instances of extraordinary dreams with which their theories are illustrated. The *Penny Cyclopædia*, also, contains an article upon dreams, which exhibits great metaphysical acumen. (See *The Royal Book of Dreams.*)

DRE′DGING MACHINE. A machine for clearing out or deepening the beds of navigable rivers, harbours, canals, &c., by the removal of deposited matters.

DRE′SSING. A term applied to gum, starch, and other articles used in stiffening or preparing silk, linen, and other fabrics.

DRE′SSINGS. In Architecture, mouldings round doors, windows, and the like.

DRIFT, in Navigation, is the angle which the line of a ship's motion makes with the meridian, when she is driven by the wind or waves and not governed by the helm. It also signifies the distance to which she is carried in a given time in that direction.

Drift. (Sax. ðrifan.) In Architecture, the horizontal force which an arch exerts with a tendency to overset the piers.

DRILL. In Mechanics, a small instrument of steel for perforating metals or hard substances. Its action is produced by communicating to it a very rapid rotation by means of a *drill-bow.*

Drill. In Agr., a machine for sowing agricultural seeds in rows; sometimes worked by the hand alone, and sometimes by the addition of a horse.

DRILL HUSBANDRY. In Agr., the cultivation of arable land, by sowing the crops in rows; the advantage of which is, that it admits of destroying the weeds, and stirring the soil in the intervals between the lines of plants. As this mode of cultivation requires some implements and machines not in use in the commoner kinds of farming, and as it is besides better adapted for some soils than for others, it is not so generally used as the obvious advantages attending it would lead us to expect.

DRIP. In Architecture, the same as Corona, which see.

DRI′PPING EAVES. (Dan. dripper, *to drop.*) In Architecture, the lower edges of a roof wherefrom the rain drips or drops to the ground.

DRI′VING NOTES. In Music, such notes as connect the last note of one bar with the first of the following one, so as to make only one note of both. They are also used in the middle of a measure, and when a note of one part terminates in the middle of the note of another, in which case it is called *binding* or *legature.* Driving notes are also called *syncopation,* when some shorter note at the beginning of a measure or half measure is followed by two, three, or more longer notes, before any other occurs equal to that which occasioned the driving note to make the number even; for instance, when an odd crotchet succeeds two or three minims, or an odd quaver two or more crotchets.

DROITS OF ADMIRALTY. The perquisites resulting chiefly from the seizure of the property of an enemy at the commencement of a war, and attached to the office of lord-high-admiral, or to the crown when that office is vacant. These perquisites were originally vested in the sovereign, to enable him to provide for the expense of defending the realm, and clearing the seas of pirates; and their value and importance will be at once perceived from the following brief statement. In 1798, one ship which had been captured brought 55,000*l.*; in 1800, another brought 65,000*l.*; in 1804, one captured ship was worth 105,000*l.*; and in 1806, several taken at once netted 155,000*l.* During the last war, also, the Dutch ships at one seizure brought 1,030,000*l.*; the Spanish ships, 2,200,000*l.*; and so large were the sums made at one and the same moment in this rich fund, that the crown one year, after paying many hundred thousands to captors, and large sums to different branches of the royal family, gave a million out of the residue to the public service. (*Edin. Rev.* vol. xxxiii. p. 482.) By the civil list introduced on the accession of William IV., it was arranged that all the droits of admiralty which might accrue during his reign should be paid into the exchequer for the benefit of the public service; and the civil list of her present Majesty has made no alteration in that arrangement. *See* Prize Money

DRO′MEDARY. *See* Camelus.

DROPS. (Sax. ðroppan.) In Architecture, the frusta of cones in the Doric order, used under the triglyphs in the architrave below the tœnia. They are also used in the under part of the mutuli or modillions of the order. In the Greek examples they are sometimes curved a little inwards on the profile.

DROP SERENE. (Lat. gutta serena.) *See* Amaurosis.

DRO′PSY. (Gr. ὕδωρ, *water.*) An unnatural collection of watery fluid in any part of the body. When it

takes place in the cellular membrane, it constitutes *anasarca;* when in the cavity of the abdomen, *ascites;* in the cavity of the cranium, *hydrocephalus;* in the scrotum, *hydrocele;* in the uterus, *hydrometra;* and in the chest, *hydrothorax*. Dropsy may arise from a variety of morbid actions, either of the secerning or absorbing vessels. When the fluid which lubricates the internal surfaces and cavities of the body is secreted in excessive quantity, or is not adequately removed by the absorbents, it may so accumulate as to constitute the various forms of this disease; it may therefore arise out of excessive as well as of defective action; it may also result from a variety of other causes connected with organic lesion or derangement, both vascular and nervous. The treatment of dropsy will of course vary with the cause of the disease: it sometimes requires depletion, and at others tonics; and local accumulation of fluids is often susceptible of removal by remedies which stimulate the absorbents to increased action, or which excite the excretories of the intestines or promote the flow of urine. Dropsy is a common symptom of a broken constitution and failure of the powers of life.

Dro'psy. In Botany, a disease peculiar to succulent plants, arising from an excessive introduction of water into the system. It produces rapid rottenness, and can only be stopt by destroying all the parts affected by it, and exposing the individual to a very dry atmosphere.

DROSO'METER. (Gr. δροσος, *dew*, and μετρον, *measure*.) Any instrument for measuring the quantity of dew that collects on the surface of a body exposed to the open air during the night. The first instrument for this purpose was proposed by Weidler. It consisted of a bent balance which marked in grains the preponderance which a piece of glass of certain dimensions, laid horizontally in one of the scales, had acquired from the settling and adhesion of the globules of moisture. A simpler and more convenient drosometer would be formed on the principle of the rain gauge; and in order to facilitate the descent of the dew down the sides of the funnel into the tube, a coat of deliqueate salt of tartar may be spread over the shallow surface. Dr. Wells, in making his celebrated experiments on dew, exposed a small quantity of wool to the open sky, and the differerence in its weight when laid down and taken up showed the quantity of moisture it had imbibed in the interval.

DROW'NING. When a person is submerged under water, suffocation ensues, not in consequence of the access of water to the windpipe or lungs, but merely from the exclusion of air, the mechanism of the glottis, or upper portion of the windpipe, being such as to prevent, by the spasmodic closure of the epiglottis, the entrance of more than a very trifling and accidental quantity of water. Under these circumstances, however, an attempt is made to inspire, which is followed by the reaction of expiration, and consequently a little air is thrown out, and the residuary quantity in the lungs still further diminished; access of oxygen to the blood is therefore effectually cut off, the aëration of the blood is prevented, and venous blood circulates in the arterial system, the right side of the heart becoming loaded with it, and the pulmonary vein returning it to the right cavities of that organ. The consequences of the non-aëration of the blood thus ensuing upon the vital functions is their suspension and rapid extinction; so that in the course of four or five minutes after the access of air has been cut off death ensues, although some of the organic functions may and do continue for a much longer period. When therefore a person has been perfectly submerged in water for the space of five minutes, perfect insensibility ensues, and the functions upon which life more immediately depends cannot be restored.

In consequence, however, of the struggles made by a drowning person, and of their chances of occasional gasps of air, and of the varying quantity of air which the lungs may contain, we must not despair of the possibility of resuscitation, even when the body has been for fifteen or twenty minutes in the water, although it must be confessed that after four or five minutes' submersion the chances of recovery are very remote.

The state of alarm and agitation into which persons falling into the water, and who cannot swim, are thrown, and their ignorance in general of the means which should be resorted to upon such an emergency, as well as want of presence of mind to adopt them, lead to neglect of those obvious measures by which immediate dangers might be averted. They should endeavour to recollect that the specific gravity of the human body when the lungs are filled with air, is less than that of water, and that consequently the body has, under such circumstances, a natural tendency to float; and that if the head can then be so placed as to keep the mouth or even the nostrils above water, respiration may be continued. They should also remember that by a forced inspiration a much larger quantity of air may be drawn into and retained in the lungs than in a common or natural inspiration; and that therefore the blood will continue longer aërated, and consequently a longer period will elapse before a second attempt at inspiration need be made, and before insensibility or the cessation of the vital functions will ensue. If, for instance, while breathing as usual, we suddenly hold our breath, we shall find ourselves forced to make an inspiration in the course of from a quarter to half a minute; but if we previously make two or three forced respirations, so as to cleanse the lungs in the first instance of foul air, and then take a forced inspiration, we shall be able to hold breath for more than a minute, and sometimes even for two minutes. It is upon this principle, that skilful divers are enabled to remain under water for a period that sometimes appears almost incredible; and if the depth of water be considerable, and the air supplied from a diving bell, its degree of condensation or diminished bulk will of course enable a given volume to oxygenate the blood more effectually than the same volume at common atmospheric pressure.

Such, then, is an outline of the physiology of drowning; it naturally leads to the important question as to the most effective means of restoring suspended animation in such cases. It of course follows from what has been said, in the first place, that not a moment is to be lost in getting the body out of the water, and removing it with the utmost speed to any place where further means can be resorted to; and now air should be thrown into the lungs, and artificial respiration should be attempted with as little loss of time as possible, for till the blood has an opportunity of being aërated, the return of the vital functions is of course impossible. The body should also be immediately stripped of the wet clothes, which should be cut off or otherwise removed with the utmost speed; and warm blankets should be at hand as wrappers, and warm towels for rubbing and drying the body. Artificial respiration, together with warmth and friction, carefully, however, and moderately employed, are the first and most essential remedies. Much has been said of the advantage in these cases of electricity; and, if possible, it should certainly be resorted to: slight shocks should be passed through the region of the diaphragm, the heart, and along the course of the spine; and various forms of the magneto-electric machine seem particularly well adapted to these purposes. The truth is, that the means to be adopted in all these cases are few and simple; but unless they are immediately at hand, and instantly available, they will fail, even under the most favourable circumstances. Yet, where even a glimmering of hope remains, they should, even under unfavourable circumstances, be as speedily and completely as possible resorted to; for there are on record extraordinary cases of resuscitation, when every thing appeared to militate against a successful issue.

But in these cases it is not only important to know what to do, but also what to avoid. Nasal stimulants, such as ammonia, aromatic vinegar, and other pungent and volatile applications, should be avoided: they can be of little use under the most favourable circumstances, and in the most judicious hands; and if unskilfully employed, may do infinite mischief. The warm-water bath is a bad substitute for warm air and friction; it interferes with the latter, and with the use of electricity, and places the body in a constrained and unfavourable position. In these days it is scarcely necessary to point out the extreme absurdity of holding the body with the head downwards, to allow the water to run out by the mouth, or the still more dangerous use of tobacco, especially of the injection of tobacco smoke,—means calculated to put the life of a healthy person in jeopardy, and every way suited to render all attempts at the restoration of suspended animation ineffectual.

DRU'GGET. A coarse and flimsy woollen texture, chiefly used for covering carpets. It was formerly extensively employed as an article of clothing by the poorer classes, more especially of females; but this and similar fabrics are now almost wholly superseded by cotton goods, which induce greater cleanliness, and are less liable to retain infectious and contagious poisons.

DRU'IDS. The priests of the Celtic inhabitants of ancient Gaul and Britain. Our classical information respecting them is chiefly derived from Julius Cæsar; Strabo, Tacitus, Pliny, Lucan, and other authors, have also left us particulars respecting them. On those slender foundations very extensive superstructures have been raised by the imagination of English and French antiquaries. The classical name of Druid was derived by the Latins from δρυς, an oak; but is more probably of Celtic origin. The doctrine of the Druids was not committed to writing, but retained by memory in the form of verses; of which the Welsh Triads are supposed, with some probability, to retain the form and vestiges. There appears to have been much of fraud and vulgar delusion mixed up in the religious rites which they practised. The gods whom they worshipped, according to classical writers, were Jupiter (Taranis), Apollo (Belenus), Mars (Hesus), and several others, whom they believed to be the same with personages of the Grecian mythology. The sacrifice of human victims is uniformly represented as a part of their worship. Their places of worship were chiefly conse-

crated groves, of one of which Lucan has given a fine description in the second book of his *Pharsalia*. The rock-altars, cromlechs, cist-vaens, and other relics of antiquity, which are scattered over the surface of parts of England and France, are attributed by antiquaries for the most part to the Druidical age. Claudius and other Roman emperors issued severe edicts against the Druids, but did not succeed in extirpating them. This was only effected by the general introduction of Christianity; and some suppose that the celebrated Culdees of Scotland and Ireland were converted Druids.

DRUM. (Dan. tromme.) In Architecture, the upright part of a cupola either above or below a dome. The same term is used to express the solid part or vase of the Corinthian and Composite capitals.

DRUM. In Music, an instrument of percussion, formed by stretching a piece of parchment over each end of a cylinder formed of thin wood, or over the top of a cauldron-shaped vessel of brass; the latter is hence called a kettle drum. The large drums which are beaten at each end are called double drums, and are used chiefly in military bands. Kettle drums are always used in pairs; one of which is tuned to the key note, the other to the fifth of the key. It is principally used for military purposes, especially for exciting the soldiers under the fatigue of march or in battle. The drum is supposed to be an eastern invention, and to have been brought into Europe by the Arabians, or perhaps the Moors. The kettle drum, the bass drum, and tambourine, are common in the East.

DRUM OF THE EAR. *See* EAR.

DRUPE. In Botany, a one-celled, one or two-seeded, superior, indehiscent fruit; the outer coat is soft and fleshy, and separable from the inner or endocarpium (stone), which is hard and bony: the whole proceeding from an ovarium, which is perfectly simple. The peach, plum, apricot, cherry, are examples of this.

DRY. (Sax. ðriȝ.) In Painting, a term applied to a painting wherein the outline is too strongly marked, and the colours of the objects do not unite with those by which they are surrounded. In sculpture it is used in speaking of a work wherein there is a want of luxuriousness and tenderness in the forms.

DRY'ADS. (Gr. δρυς, *an oak*.) In the Heathen Mythology, a kind of imaginary female deities whom the ancients believed to inhabit the woods and groves.

DRY DISTILLATION. This term is applied to the distillation of substances *per se*, or without the addition of water: thus if we put wood into a retort or other distillatory apparatus, and subject it to heat, it yields tar, vinegar, water, and various gaseous and other matters, which are called the products of its *dry* or destructive distillation.

DRY'ING OIL. This term is generally applied to linseed and other oils which have been heated with oxide of lead; they are the bases of many paints and varnishes.

DRY ROT. A disease which attacks wood, rendering it brittle, and destroying the cohesion of its parts, is known by this name. It occurs among the timbers of ships, where it sometimes commits the most serious damage, and in damp ill-ventilated houses. It is usually ascribed to the attacks of fungi, especially to such as *Polyporus destructor* and *Merulius lachrymans*, whose filamentous spawn or thallus appears upon the surface, overspreading it like a tough thick skin of white leather; and there is no doubt of its being often connected with the appearance of such fungi. But dry rot is certainly, in some cases, to be identified with the presence of fungi of a more simple kind than those just mentioned; especially of such as belong to or resemble the genus *Sporotrichum*.

The destruction of timber by such plants is effected in part by the disintegration of the tubes of the weed, in consequence of the introduction between them of the fine filamentous spawn of the fungi, and in part by the dampness which is thus conveyed to the interior of the wood, where it soon produces decomposition. It is not, however, certain that dry rot is always caused in this manner; on the contrary, the term appears to be frequently applied to cases of spontaneous decomposition of timber without the presence of fungi, or when the appearance of the latter takes place long after the commencement of the disease.

When dry rot produced by fungi has once made its appearance, there is no means of arresting its progress without removing the whole of the diseased and neighbouring parts; and even then it will probably again break out, unless means can be taken to introduce a circulation of fresh air among the parts liable to the affection. For if timber is allowed to remain in a damp situation, and in the dark, it affords so favourable a nidus for the seeds of fungi, that they are almost certain to vegetate upon it; unless some means have been previously taken to render the timber permanently unsuited to their growth. This end appears to have been attained by Mr. Kyan, who has obtained a patent for pickling timber, as a preventive of the dry rot, and who employs for this purpose a solution of corrosive sublimate. This salt of mercury is a well-known vegetable poison: if any animal jelly, upon which fungi will quickly appear in the form of mouldiness, is mixed with a minute quantity of corrosive sublimate, no fungi will in that case be produced; so that both theory and experience are in favour of Mr. Kyan's process. It is not improbable that the progress of dry rot might even be arrested in the buildings where it occurs, if the timbers could be got at and well washed with the same solution.

Although dry rot generally fixes itself upon timber, it will also attack any form of vegetable matter. The paper hangings of rooms, chiefly composed of cotton and linen thread, are occasionally overrun in houses which have been long shut up and neglected; and the mildew which destroys the strength of canvass is only another form of dry rot, the appearance of which is altered by the special circumstances under which the fungus is developed, or by the species of the fungus itself.

DRY'SALTER. A dealer in salted or dried meats, and in the materials used in pickling, salting, and preserving various kinds of food; hence drysalters usually sell a number of saline substances and miscellaneous drugs.

DRY'STOVE. A glazed structure for containing the plants of dry arid climates; such as the cactuses, mesembryanthemums, aloes, and other succulents of Africa.

DU'ALISM. A name given to those systems of philosophy which refer all existence to *two* ultimate principles. Dualism is a main feature in all the early Greek cosmogonies, and is that which distinguishes them from the eastern speculations on similar subjects, which mostly regard all things as *emanating* from a single principle. The dualistic hypothesis was, doubtless, originally suggested by the analogy of male and female in animal existence. The earliest forms under which the theory appeared are, as might be expected, rude in the extreme. The Orphic poets made the ultimate principles of all things to be Water and Night; by others Æther and Erebus, Time and Necessity, are severally deemed worthy of this distinction. (*Brandis, Gesch. der Phil.* i. p. 71.; *Arist. Metaph.* xix. 3.) The ancient Greek and Roman mythology was evidently constructed on this principle. (See *Varro, De Re Rustica*, i. 2.) In its more philosophic form, the dualistic theory was maintained among the ancients by Pythagoras and many of the Ionian school; among the moderns, chiefly by Descartes. (*See* arts. IONIC PHILOSOPHY, CARTESIAN PHILOSOPHY.) It may be expressed generally as the assumption of the coeternity and simultaneous development of the formative with the formed, of the *natura naturans* with the *natura naturata*. So the system of philosophy which regards matter and spirit as distinct principles is a species of dualism, as opposed to materialism.

In Theology, the doctrine of the two sovereign principles of good and evil (*see* MANICHEISM) is also dualistic; and the high Calvinistic theory may be said to be a species of dualism, viz. that all mankind are divided, in the eternal foreknowledge of God, and by his arbitrary decree, into two classes, — tne elect and reprobate.

DU'AL NUMBER, in Grammar, is the name given to that form of the verb and substantive by which, in the ancient Greek, Sanscrit, and Gothic, and the modern Lithuanian languages, *two* persons or things are denoted, in contradistinction to *plural*, which expresses an indefinite number of persons or things. For full discussions on the nature and peculiarity of the dual number, see *Buttmann and Matthäi's Greek Grammar*; see also the *Penny Cyclop.*, and the authorities there referred to.

DU'BBING OUT. A term used by plasterers to signify the bringing of an uneven surface to a plane by pieces of tiles, slate, plaster, or the like.

DUCAT, DUCATOON. *See* MONEY.

DUCK. *See* ANAS.

DUCKBILL. *See* ORNITHORHYNCHUS

DUCTI'LITY. (Lat. duco, *I draw*.) A property of certain bodies, in consequence of which they can be *drawn out* at length without suffering any interruption of the continuity of their constituent particles. The term ductility is frequently confounded with malleability, or that property of bodies through which different forms can be given to them by pressure or percussion. In general ductility depends, in a greater or less degree, on the temperature. Some bodies, wax for example, are rendered ductile by a small degree of heat; while glass requires a violent heat before it acquires ductility. Some of the metals — for example, gold, silver, lead, &c. — are ductile under all known temperatures.

"The ductility of some metals far exceeds that of any other substance. The goldbeaters begin their operations with a riband an inch broad and 150 inches long, which had been reduced, by passing it through rollers, to about the 800th part of an inch in thickness. The riband is cut into squares, which are disposed between leaves of vellum, and beat by a heavy hammer till they acquire a breadth of about three inches, and are thus extended to ten times their former surface. These are again quar-

tered, and placed between the folds of goldbeaters' skin, and stretched out by the operation of a lighter hammer to the breadth of five inches. The same process is repeated, sometimes more than once, by a succession of lighter hammers; so that 376 grains of gold are thus finally extended into 2000 leaves of 3·3 inches square, making in all 80 books, containing each of them 25 leaves. The metal is consequently reduced to the thinness of the 282,000th part of an inch, and every leaf weighs rather less than the fifth part of a grain. A particle of gold, not exceeding the 500,000th part of a grain, is hence distinctly visible to the naked eye."

"It has been asserted that wires of pure gold can be drawn of only the 4000th part of an inch in diameter; but Dr. Wollaston, by an ingenious procedure, has lately advanced much farther. Taking a short cylinder of silver, about the third part of an inch in diameter, he drilled a fine hole through its axis, and inserted a wire of platinum only the 100th part of an inch thick. This silver mould was now drawn through the successive holes of a steel plate, till its diameter was brought to near the 1500th part of an inch; and consequently the internal wire, being diminished in the same proportion, was reduced to between the 4000th and 5000th part of an inch. The compound wire was then dipped in warm nitric acid, which dissolved the silver, and left untouched its core, or the wire of platinum. By passing the incrusted platinum through a greater number of holes wires still finer were obtained, some of them only the 30,000th part of an inch in diameter. The tenacity of the metal, before reaching this limit, was even considerable; a platinum wire, of the 18,000th part of an inch in diameter, supporting the weight of a grain and a third." (*Leslie's Elements of Nat. Philosophy.*)

Glass, when well softened by the fire, becomes as ductile as soft wax, and may be spun out into threads of greater fineness than any hair, and which bend and wave like hair in the wind. The method of producing these threads is exceedingly easy. Two workmen are employed; the first holds the glass over the flame of a lamp; the second applies a hook to the metal in fusion, which, when drawn back, brings with it a thread of glass, still adhering to the mass; the hook is then fitted on the circumference of a wheel, which, being turned round, draws out the thread, and winds it about its rim. Some of these threads are scarcely larger than that of a silkworm, and are surprisingly flexible.

DUCTS. Those membranous tubes in the internal anatomy of plants which have conical or rounded extremities; their sides being marked with transverse lines, or rings, bars, or dots, arranged spirally, and being incapable of unrolling.

DU'EL (Lat. duellum, *a conflict between two individuals;* in the original use of the Roman word, *between two states*), signified originally a trial by battle resorted to by two persons as a means of determining the guilt or innocence of a person charged with a crime, or of adjudicating a disputed right; but in more modern times it is used to signify a hostile meeting between two persons, arising from an affront given by one to the other, and for the purpose (as is said) of affording *satisfaction* to the person affronted.

The practice of the duel, as a private mode, recognized only by custom, of deciding private differences, seems to be of comparatively recent date, and descends by no very direct transmission from the ancient appeal to the judicial combat as a final judgment in legal disputes. That it originated with the feudal system is abundantly clear, if it were only from the fact that in Russia, where that system was never known, the custom of the duel was unheard of, until introduced by foreign officers even within the memory of the present generation. But it is certain that many antiquarian writers have confused together two very different institutions: the *appeal to arms*, as an alternative for the trial by ordeal or by compurgators, appointed by traditionary usage from the earliest periods of Germanic history; and the *voluntary challenge or defiance*, resorted to for the purpose of clearing disputes involving the honour of gentlemen. This last custom was first elevated to the dignity of an established institution by Philip le Bel of France, whose edict regulating the public combat between nobles bears the date of 1308: the best comment on which may be found in the spirited and accurate representation, by Shakspeare, of the quarrel between Mowbray and Bolingbroke.

The duello, in this its high and palmy state, when favoured by princes and tolerated by the church, became the subject of many fantastic regulations, partly framed on the imaginary code of chivalry, and partly on the precepts of the civil law. Thus, in a curious treatise on this subject by Dario Attendoli, an officer of the Italian wars (printed in 1565), we find it laid down that not less than twenty days must elapse between the receipt of a cartel or challenge and the answer; because such was the time required to elapse, in civil suits, between the plaintiff's charge and the defendant's first pleading. Three, four, or five months must then be allowed to the champions for preparation. The combat must take place in lists, and under the eyes of the sovereign authority of the city selected by the challenger. The strictest equality of rank must be observed between the parties; a rule which appears to have been tolerably well attended to, and must have saved the shedding of much unnecessary blood. But, while every precaution was taken to render such duels not easily to be engaged in on light grounds, it was part of the same code that they should be carried through in serious earnest. In another curious Italian book of problems concerning the duel (of the same date), the question is put, "Whether a prince will do well or ill in separating two champions, when both shall be so weakened by loss of blood as to appear unable to continue the combat?" and resolved in the negative. And if the vanquished had his life spared him, he was bound to consider himself the prisoner of his conqueror, and devoted to his service, until released by death or by positive permission; although Attendoli intimates that, in his opinion, the limitation of thirty years, according to the maxims of the civil law, ought to apply to this servitude.

The particular regulations of these Italian laws of honour are of the most curious and pedantic minuteness. Attendoli has favoured us with several common precedents of challenges and answers. The commencement of the cartel, "per injuria di fatti," for injury in deeds, runs as follows: — "I, M., having been by thee, N., enormously beaten with a stick (superchievolmente con un bastone percosso) at Rome, on the —— ultimo, after an evil fashion, from behind, I not being aware of thee, and in time of peace, say to thee that thou hast done basely and wickedly, and as a traitor and vile cavalier." To this cartel are appended the signatures of four witnesses, who affirm themselves to have been present at the administering of the bastinado. The cartel was to be publicly placarded in the streets; as was also the answer, or, if the adversary declined the combat, a statement of his refusal. In this latter case, it was debated whether it were not allowable to hang up a likeness of the person declining to fight; but this singular species of posting, although we are told it was not uncommon, is reprobated as unbecoming a gentleman. The distinctions as to persons are not less amusing. (See *e.g.* question 3d of the Book of Problems in the treatise of Attendoli above referred to.)

The fashion of the public duel seems never to have prevailed to any extent in England. Although the ancient Judicium Dei was so interwoven with our laws that, at a comparatively late era, the whole court of Common Pleas would occasionally adjourn in full term to Smithfield or Bankside, to see the long-contested intricacies of a "writ of right" brought fairly to issue in a match at singlestick; yet the stern necessity of washing out affronts in blood, whether in open or private quarrel, does not seem to have been strictly adhered to until the latter part of the reign of Queen Elizabeth. Then the the imaginations of the young nobles of the court, heated with the favourite study of chivalry, readily adopted the sanguinary practice of foreign realms. At this period appeared the famous *Treatise of Honour* of Vincentio Saviolo — a fierce and punctilious Italian, a fencing master by profession, bred in the wars of Italy, and deeply versed in the science of the public duello, then a favourite theme of reminiscence, although no longer known in practice, as will be presently shown. This little work, published in 1594, — now little known to us, save by the famous quarrel in Shakespeare's *As You Like It*, concerning the cut of the courtier's beard, which seems intended as a parody on some parts of it, — appears to have been adopted by the gallants of the time as a standing book of reference in all cases of supposed insult. Saviolo resolves all quarrels into the lie, — that is, he supposes the original insult to be followed, either expressly or impliedly, by a regular series of replies and retorts, until one or the other party is reduced to give the lie direct; which, like the phrase "stupid youth" (*dummer junge*), in some German universities, was immediately followed by the appeal to arms.

> That ordinary commotioner the lie,
> The father of most quarrels in this climate,

appears to have been raised to this "bad eminence" by Francis the First, the great guide of his day in matters of chivalry, who first gave it as his opinion, that the lie could under no circumstances be brooked by a man of honour. Attendoli holds that the virtue of the insult lies mainly in the word lie; and that any circumlocution, however plain, greatly deprives it of its effect. This, however, Saviolo stoutly denies; and maintains that an imputation on the veracity of a party, in whatever words it may be couched, is equally deserving of resentment. The lie, being a matter of so great importance, became the subject of much nice distinction; insomuch that a note to *Dr. Moore's Essay on Duelling* informs us, that they enumerated thirty-two different ways of giving the

lie in the latter part of the sixteenth century. Saviolo, however, contents himself with the division into the lie direct and lie circumstantial; each of which he subdivides into general and special; besides a fifth sort, which he calls "fictitious" or "sham" lies. These, he says, seem to have originated from the custom that he who receives the lie direct, or last retort, being of necessity the challenger, has the choice of weapons; to gain which advantage it was not unusual for one who sought a quarrel to address his enemy with, "If you say I am a scoundrel, you are a liar;" by which means they supposed that the latter was put to the necessity of making a direct reply. In opposition to this notion, Vincentio shows divers honourable devices by which an ingenious duellist, when assailed in this manner, may retort on his adversary, so as to throw the burden of the last word on him. Paris de Puteo, a Neapolitan lawyer, is said to have practised chiefly in this branch of business, and to have answered cases on the point of honour put to him from all parts of Europe.

Yet, however extravagant the foolery of these early writers may seem on a matter of such serious nature, it must be confessed that, retaining as they did much of the old opinion, refined into a sentiment, respecting the immediate interposition of God in the judicial combat, the true point of honour was far safer in their hands than in the less scrupulous ones of the professed duellists of modern times. Saviolo does not hesitate earnestly to inculcate on his pupil the duty of maintaining no cause except that which he seriously believes to be just and true, and of submitting to any humiliation rather than fight in defence of a falsehood. A fine, although somewhat extravagant illustration of this chivalric principle, may be found in the old play of *A Fair Quarrel*, by Middleton and Rowley. Captain Ager, the hero of the piece, is saluted by his colonel on the occasion of some dispute with the appellation of "son of a whore." A challenge follows, and time and place are fixed; but the captain cannot satisfy his conscientious honour without repairing to his mother, and acquainting her, although indirectly, with the provocation he has received. She, suspecting his meaning, and fearing for his life, in a moment of weakness falsely intimates the imputation to be a true one. The captain's mind is instantly made up—he will not fight in a bad quarrel; but, for his mother's sake, he will not divulge the reason. His two seconds arrive, and he hears, with seeming equanimity, their expostulations, and at last their insults, declaring that although he is ready to follow them to the field, he will not fight a stroke. But, being branded on that account by his adversary with the epithet "coward," he thankfully seizes on the opportunity afforded him by this fresh insult; draws in "a fair quarrel," and overthrows his opponent.

In 1547, Henry II. of France issued an edict absolutely prohibiting the judicial or public combat. This decree was produced by the death of his favourite, La Chataigneraye, in consequence of wounds received in the lists in the presence of Henry himself. By a curious coincidence, the abolisher of one of the grand institutions of the feudal ages was destined, in his own person, to be the cause of the disuse of another: he was slain in a tournament, and that knightly exercise was no longer practised at courts after that melancholy event. The public duel survived some time longer in Italy, as may be seen by the dates of the treatises quoted above. Its abolition in France was by no means followed by the good effects which the statesmen of those days probably anticipated from it. Debarred from public conflict, the gentlemen of France were at the same time freed from its manifold restraints; and private duels, conducted with a ferocity and sanguinary spirit hitherto unheard of, became prevalent to the most astonishing degree. The wars of religion, prosecuted with a degree of bitterness perhaps unexampled in the history of any nation, added public causes of dispute to those of an hereditary and personal nature. Even the ordinary laws of honour, which seem inseparable from the practice, were neglected. We find in Brantome, that there were duellists who prided themselves on the advantages which they had taken of their antagonists, and were not esteemed the less in society for having done so. Not only had individuals and families their quarrels; we are told that there were regiments in the same service, of which the officers were bound to fight one another whenever they met. The duellist seems to have usurped, with the fair sex, the attentions usually paid to the soldier. We have the testimony of Lord Herbert of Cherbury, himself a vain and cold-blooded quarreller, for the honour in which the ladies of France held the brave Balagny—an ordinary man, in a threadbare doublet and grey breeches, with neither figure, wit, nor fortune to recommend him; but whose testimonials consisted in the fact of his having killed eight or nine of his friends in single combat.

It was about the reign of Henry III. also, that the sanguinary custom of the seconds taking part in the quarrel of their principals seems first to have become established, a custom which only gradually wore out in the beginning of the last century. When such bloody practices were rife in all parts of France, we are scarcely tempted to doubt the extraordinary assertions we find in the writers of those days,—that one hundred and twenty gentlemen were killed in duels, in a single French province, in six months; that in the reign of Henry IV. four thousand fell in two years; that this strange species of mania cost France more gentle blood than thirty years of civil war. Henry IV. issued edicts against duelling; Louis XIII. proceeded against it at one time with such severity, that we are told that wounded duellists were dragged at once from the field to the gibbet; but this unwarrantable violence, as usual in such cases, had no effect. The evil at length produced a remedy by its own excess. In the minority of Louis XIV. the Duke de Nemours, a prince of the blood, fell, with two of his four seconds, in a quarrel with another grandee of the court. After this deplorable event, many noblemen and gentlemen of undoubted courage entered into a voluntary compact to abstain from duelling. Louis XIV., when of age, approved of their resolution, and seconded it by several edicts. To the honour of this prince, it should be remembered that during the whole of his life he laboured firmly and temperately to correct this abuse, and with no ordinary success. This he effected, not merely by the force of laws, but by exhibiting in his own demeanour, and encouraging in his courtiers, that mixture of dignity with gentleness which most readily turns away wrath and repels insolent familiarity. One of his expedients, however, it must be admitted, seems to our modern ideas not very likely to attain the object proposed. This was the establishment of a court of chivalry,—the members of which were the marshals of France,—which was to decide on all questions in which a gentleman might conceive his honour to be involved. It is said that this singular sort of arbitration was at first very efficacious; although in Mercier's time (the reign of Louis XVI.) he tells us (as we might naturally suppose) that a person who should have resorted to the court to redress an insult would only have incurred ridicule, in addition to the disgrace of not personally resenting it. Various laws relating to the duel have been since made in France, but have fallen into disuse for the most part. Whether slaying in a duel be murder, is a point on which there has been a continual conflict between the courts of cassation and the royal courts since 1817, when it was raised in the case of De Poligny and Rosay. But the legal question is of comparatively small importance, from the licence assumed by juries in that country. A civil action lies on behalf of the friends of the slain man.

In England, the first attempt made to introduce legislative enactments in aid of the common law for repressing of duels is said to have taken place in 1713; when, after the celebrated duel of Duke Hamilton and Lord Mohun, a bill for that purpose was brought into the Commons, but lost on the third reading. A provocation or challenge to fight is a high misdemeanor. In Scotland, as late (we believe) as the middle of the 16th century, licences for duelling were granted by the crown, and formed a source of revenue: death in a duel without licence was murder. (See *Pitcairn's Criminal Trials*.) The new codes of Bavaria and Prussia contain a number of provisions, with perhaps too much minuteness of distinction, against duels, challenges, &c. The common punishment is imprisonment for a shorter or longer term.

See as to duels, in addition to former works on the subject, *Fougeroux de Campigneulles, Histoire des Duels*, 3 vols. 8vo. 1834; in which most authorities are collected, although it is a compilation including many anecdotes, &c. of no authenticity. For modern legislation on the subject, the article "Duel," in *Ersch and Gruber's Encyclopædia*, may be consulted with advantage.

DUE'NNA. (Span. dueña.) The chief lady in waiting on the queen of Spain. In a more general sense, it is applied to a person holding a middle station between a governess and companion, and appointed to take charge of the junior female members of Spanish and Portuguese families.

DUE'T. (Lat. duo, *two*.) A piece of music composed for two performers, either vocal or instrumental.

DUGO'NG, or DUYONG. The name of a herbivorous cetaceous animal, characterized by two large permanent incisive tusks in the upper jaw, and four molar teeth above and below, the grinding surface of which exhibits a rim of cementum surrounding a slight excavated centre of ivory. The upper lip is beset with numerous strong bristles, and similar ones are found more sparingly scattered over the body. The anterior extremities are fin-like, and without nails. The caudal fin is broad, and of a crescentic figure. One species (*Halicore Indicus*, Cuv.) inhabits the seas of the Indian Archipelago. A second dugong has been recently discovered in the Red Sea (*Halicore tabernaculi*, Ruppel), but which is at most only a variety of the preceding. The fabled mermaid seems to have been founded on the dugong.

DUKE. (From the Latin dux, *leader or commander*.)

The title of Duke is said to have originated in the usages of the Lower Empire, where it was given to the military governors of provinces. From thence it was borrowed by the Franks, who adopted, in many respects, the titles and distinctions of the empire. Charlemagne is said to have suffered it to become obsolete, but the emperor Louis created a duke of Thuringia in 847. In course of time, according to the usual progress of feudal dignities, the title became hereditary. In Germany the dukes became the chief princes of the empire; this title being proper to all the secular electors, and to most of the greater feudatories. In other countries their dignity became merely titular. In Italy and France dukes form the second rank in the nobility, being inferior to princes: in England they form the first. The title was not known in the latter country until the reign of Edward III.; and the word dux is used by writers before that period as synonymous with count or earl. In the eleventh year of the latter monarch the dignity of Duke of Cornwall was bestowed on his eldest son, Edward the Black Prince. In the year 1351, his third son, John of Gaunt, Earl of Lancaster, was created Duke of Lancaster for life, furnishing the next instance of this dignity. In neither of these instances, nor in any subsequent one, according to Sir H. Nicolas (*Introduction to the Peerage*, vol. i. p. lxxvii.), was the dignity thus created a dukedom by tenure: it has always remained a personal title only, and descendible according to the limitations of the charter.

DULCAMA'RA. (Lat. dulcis, *sweet*, and amarus, *bitter*.) The common woody nightshade, the stalk of which is used in medicine to furnish a decoction which is somewhat narcotic and diuretic, and has a very peculiar bitter-sweet flavour. It has been recommended in chronic rheumatism, and as an alterative in some cutaneous cases, but is not much depended upon.

DU'LCIMER. (Etym. uncertain.) A musical instrument, of what description is unknown, but probably of the wind species, in use among the Jews.

DU'MBNESS. (*Aphonia* of medical writers; from α, privative, and φωνη, *voice*.) This term is generally applied to persons who are either born deaf, or become so in early infancy; the consequence of which is that the organs of speech have never been called into due action, their functions being at first imitative in respect to sounds, and the numerous muscles of the tongue, glottis, &c. concerned in speech remain inactive; for persons who even in very early life become deaf are not rendered dumb, the organs of speech having been once called into activity, and having acquired their peculiar powers and consentaneous actions. Dumbness may also arise from injury to the lingual nerves, or from great general or local debility; in which case blisters, stimulants, tonics, and other remedies may be resorted to for the restoration of speech. It is remarkable that the loss of the tongue, and even of part of the palate, does not necessarily occasion dumbness: this has happened from disease, and among barbarous nations the tongue was occasionally extirpated; yet cases are on record showing that even under such circumstances speech was more or less perfectly retained; and there is an account in the *Memoires de l'Academie des Sciences* for 1718 of a girl who was born without a tongue, and yet acquired the faculty of speech. The case of Margaret Cutting, related in the *Philosophical Transactions* (1742) by Dr. Parsons, may also be consulted in reference to this subject.

DU'MUS. In Botany, a low and much-branched shrub.

DUNES. (Ang. Sax. *low hills*.) Hills of moveable sand, which are met with along the sea coast in various parts of Great Britain, Ireland, and the Continent. The mode of their formation and progress is exceedingly curious. In various districts the sea deposits on the beach a quantity of fine sand, which is carried forward by the wind till it meets with some obstruction in the shape of large stones, roots of trees, or other obstacles, when it gradually accumulates into mounds or hillocks, "whose general appearance, size, and distribution depend on those of the obstacles to which they owe their existence." When these mounds have attained a certain elevation they are urged forward upon the land; for, as Cuvier observes, "le même vent qui éleve le sable du rivage sur la dune jette celui du sommet de la dune à son revers opposé." The direction which they take depends chiefly on that of the wind; and their inroads upon the land are attended by the most destructive effects. One of the departments of France, the Landes, has been nearly overwhelmed by their progressive advance. The quantity of moveable sand which the sea annually deposits on that coast has been estimated at upwards of 3,000,000 square feet, and its annual progress inland at about 72 feet. In that department the dunes advance in a north-easterly direction; and it has been calculated, with apparently sufficient exactness, that unless their progress be arrested, they will have reached Bordeaux in 1500 years. During the violent hurricanes which frequently occur in these regions, the whole mass of sand of which the dunes are composed appears to be in agitation; and such is the rapidity with which they then advance, that entire villages, fields, and gardens are almost instantaneously engulphed, and the aspect of whole districts changed within four and twenty hours. The progress of the dunes, however, as already remarked, is in general slow and steady. Thus the town of Mimizan, after struggling for more than the fourth part of a century against their encroachments, is now almost buried beneath them; and such have been their destructive effects upon a village of Britanny, that nothing is visible of it except a small part of the church steeple. As will be easily imagined, the means of arresting the progress of the dunes forms a most interesting and important inquiry. For this purpose various measures have been recommended; but by far the most efficient means hitherto adopted consists in planting close together, so as to form, as it were, a line of defence against the sand, such trees and shrubs as are known to thrive in a barren soil. This process, wherever it has been tried, has been found not only to fix the dunes, but at the same time to form a simple and secure barrier against all further encroachment of the sand.

DU'NKERS. A Christian sect, which formed itself into a society under peculiar rules in Pennsylvania in the year 1724. The origin of their name is unknown. They practise abstinence and mortification, under the idea that such austerities are meritorious in the sight of God, and effective, first in procuring their own salvation, and further in contributing to that of others. They form a society strictly connected within itself, and hold love feasts in which all assemble together; but their devotions and ordinary business are carried on in private, nor do they recognize a community of goods. They also deny the eternity of future punishments; conceiving that there are periods of purgation, determined by the sabbath, sabbatical year, and year of jubilee, which are typical of them.

DU'NNAGE. Any light or loose material, as wool, &c., used as a bed in the stowage of heavy articles.

DUODE'CIMAL. (Lat. duodecim, *twelve*.) Proceeding by twelves. The term is given to a rule or operation of arithmetic, by which the contents of any surface or solid are found by multiplying together its linear dimensions, expressed in feet, inches, and lines, and is consequently much used by artificers in finding the contents of their work. The rule is also called cross multiplication, from the manner in which the operation is usually performed, and which is as follows: Suppose it were required to find the superficial content of a plank 12 feet 9½ inches long, and 3 feet 7 inches broad. Set down the two dimensions under each other, placing feet under feet, inches under inches, &c., and for the half inch put down its equivalent 6 lines, as in the following example: —

$$\begin{array}{rrr}
12 & 9 & 6 \\
3 & 7 & \\
\hline
38 & 4 & 6 \\
7 & 5 & 6\frac{1}{2} \\
\hline
45 & 10 & 0\frac{1}{2} \\
 & 12 & \\
\hline
 & 120\frac{1}{2} &
\end{array}$$

Now, since the feet are conceived to be units of measure, the inches are so many 12ths of unity, and the lines so many 12ths of a 12th, or 144th parts of unity. The units consequently form the first column, the 12ths the second, and the 144ths the third. Multiplying therefore the first line by 3 feet or 3 units, we get 38 feet, 4-12ths of a foot, and 6-144ths of a foot. Next, multiplying the upper line by 7-12ths, we get first the 6 lines or 6-144ths, multiplied by 7-12ths, equal to 42-1728ths, which is equal to 3½-144ths. Then the 9-12ths multiplied by the 7-12ths give 63-144ths, which added to the 3½ make 66½-144ths, or 5-12ths and 6½-144ths; therefore 6½ is placed in the third column, and the 5-12ths carried on. Lastly, the 12 units multiplied by the 7-12ths give 84-12ths, which added to the 5-12ths make 89-12ths, and this is equal to 7 units or feet and 5-12ths; consequently 7 is placed in the first column and 5 in the second. Adding the two products together, we get 45 feet, 10-12ths of a foot, and ½-144ths of a foot. But in square or superficial measure the 144th part of a foot is an inch; and 10-12ths = 120-144ths; consequently the result of the operation is 45 sq. feet and 120½ sq. inches.

The operation is itself much simpler than the description or explanation, which is found embarrassing to beginners; it would therefore, perhaps, be better to reject the rule altogether from elementary books of arithmetic; and, regarding the inches and lines as parts of a foot, to perform the operation by the ordinary rule of *practice*.

DUODE'CIMO. (Lat.) A book is said to be in *duodecimo* (abbreviated 12mo.), when every sheet being six times folded makes twelve leaves or twenty-four pages.

DUODE'NUM. (From duodenus, *consisting of twelve*.) The commencement of the intestinal canal, forming a division, which in some animals is about as long as the breadth of twelve fingers. This term, introduced by the older anatomists, is still applied to that portion of the intestines, though the measure is generally inapplicable.

DU'PLICATE RATIO, is the ratio of the squares of two quantities, or the square of their ratio. Thus the ratio

of a^2 to b^2 is the duplicate of the ratio of a to b. If there be three quantities in continued proportion, the first is to the third in the duplicate ratio of the first to the second: — thus if a, b, c be continual proportionals, that is, if $a : b :: b : c$, then a is to c in the duplicate ratio of a to b.

DUPLICA'TION OF THE CUBE. A celebrated problem of the ancient geometry. While a plague was desolating Athens, a deputation was sent to consult the oracle of Apollo at Delos, who returned for answer that the plague would cease when they had doubled the altar of the god. The altar was cubical, consequently the problem was to find the side of another cube of twice the solid contents. As this problem requires the solution of a cubic equation, it cannot be solved by plane geometry; but Hippocrates of Chios reduced it to another; namely, the insertion of two mean proportionals between two given straight lines, a problem which several of the ancient geometers, particularly Archimedes, Eutocius, Pappus, and Nicodemes, discovered methods of constructing by means of the higher curves. Among the modern geometers who have not disdained the same inquiry, are the illustrious names of Newton and Huygens. See *Montucla, Histoire des Mathematiques*.

DU'PPER, or DUBBER. A globular short-necked vessel made of buffalo's hide, in which castor oil is imported from India. Each dupper holds about 80 lbs. of oil.

DU'RA MATER. A thick membrane enveloping the brain and adhering to the inner surface of the cranium. *See* BRAIN.

DURA'MEN. (Lat.) The fully formed central layers of the wood of Exogenous trees; what is called in common language the heart wood. It is only the sapwood solidified by the introduction of various secretions into the interior of the cells or tubes of which such wood is composed.

DU'RESS (Lat. duritas, *hardship*), in Law, is such constraint, either actual or by threats occasioning a reasonable fear, as will invalidate legal acts done by a party suffering it. Duress of imprisonment must be by illegal imprisonment. Duress per minas, by threats, is interpreted to mean such threats as occasion fear of life or limb.

DUTCH GOLD. Copper, brass, and bronze leaf is known under this name in commerce; it is largely used in Holland for ornamenting toys and paper.

DUTCH SCHOOL. In Painting, this school, generally speaking, is founded on a faithful representation of nature, without attention to selection or refinement. The ideas are usually low, and the figures local and vulgar. Its merit lies in colouring and drawing with extreme fidelity what was before the eye of the artist. The pothouse, the workshop, or the drunken revels of unintellectual boors, seem to have furnished its principal subjects. The great appearance of reality infused into its productions induced Hagedora to call it the School of Truth. Notwithstanding its deficiency in all that tends to raise the mind, it has gained an unspeakable lustre from its great head, Rembrandt van Rhyn, to whose name may be added those of De Leide, Heemskirk, Polemburg, Wouvermans (an exception to our general observations), Gerard Dow, Mieris, and Vandevelde, &c.

DUU'MVIRI. A general appellation, among the ancient Romans, given to any magistrates elected in pairs to perform any function or class of functions. The chief Duumviri were the Duumviri Sacrorum, to whom were entrusted the care and the interpretation of the Sibylline books. The Duumviri Municipales had almost consular power in the municipal cities. The Duumviri Navales were officers appointed to man, equip, and command the Roman navy.

DWA'RFING TREES. Dwarf trees may be produced in three different ways: by grafting on dwarf slow-growing stocks, as, for example, the pear on the quince; by planting in pots of small size filled with poor soil, by which the plant is starved and stunted; and by causing a portion of the extremity of a branch to produce roots, and then cutting it off and planting it in a pot or box of poor soil. This last is the Chinese method, and is thus performed: — The extremity of a branch two or three feet in length, in a fruit or flower-bearing state — for example, the points of the branches of a fir tree bearing cones, or of an elm bearing blossom buds — being fixed on, a ring of bark is taken off at the point where it is desired that the roots should be produced. The space thus laid bare is covered with a ball of moist clay, which is kept moist by being covered with moss, which is occasionally watered. In the course of two or three months in some trees, and of a year or two in others, roots are protruded into the ball of clay. The branch may then be cut off below the part from whence the roots have been protruded, and the branch being planted in a pot of poor soil, and kept sparingly supplied with water, it will remain nearly in its present state for many years; producing leaves, and perhaps flowers, annually, but never shoots longer than a few lines.

DWARF WALL. (Sax. ðpeorh.) In Architecture, a low wall, not so high as the story of a building in which it is used.

DY'EING. The object of this beautiful art is to fix certain colouring matters uniformly and permanently in the fibres of wool, silk, linen, cotton, and other substances. There are a few dyeing materials which impart their colour to different stuffs without any previous preparation, and these have been technically termed *substantive colours;* by far the greater number, however, of colouring materials, only impart a fugitive tint under such circumstances, and require that the stuff to be dyed should undergo some previous preparation, in order to render the colour permanent; that is, capable of resisting the action of air, light, and water. The substance applied with this intention is called a *base* or *mordant*, and must posesss an affinity for the fibre of the stuff on the one hand, and for the colouring materials on the other. The mordant often effects another important object; that of changing or exalting the colour at the same time that it fixes it. The principal mordants are aluminous earth and oxide of iron, and these are usually applied in the state of acetates. As an instance, we may mention the mode of dyeing calico red by means of *madder*, a decoction of which, if applied to the unprepared goods, would only give them a dirty red tinge, neither agreeable nor permanent. If the calico be previously passed through a weak solution of acetate of alumina, and then dried at a high temperature, and afterwards washed, a portion of the alumina is retained in chemical combination with the fibre of the calico; and when thus prepared and submitted to the action of a hot decoction of madder, and again washed, it comes out of a fine red, which is fixed in consequence of the attraction of the alumina for the peculiar principle which gives colour to the madder. If the mordant be oxide of iron instead of alumina, the colour which is then produced is purple; and various shades and colours are obtained by mixing mordants, by using more or less of them, and by applying the coloured solutions in various states of concentration. Sometimes articles are dyed by a similar precipitation of coloured metallic oxides in the fibre; thus yellow is obtained by passing cloth impregnated with acetate of lead through a solution of chromate of potash: a double decomposition ensues, and yellow chromate of lead is precipitated in and combined with the vegetable or animal fibre. Blues are produced by passing the goods previously mordanted with iron through an acidulated solution of ferrocyanate of potash; these are generally called *chemical colours*, though not in fact more so than the others. Scarlet is exclusively produced by the colouring matter either of the cochineal or of the lac insect, which is fixed by oxide of tin, or by alumina, and heightened by the action of tartar.

The chemical principles of the art of *calico printing* are the same as those of dyeing, but the details are more difficult and complicated; and in consequence of the combination of a great variety of colours upon the same ground, the process is sometimes extremely refined and intricate; so that a rich, varied, and pleasing pattern, thus effectively produced, may be considered as a triumph of practical skill over theoretical difficulties, which is scarcely rivalled, and certainly not excelled, in any other of the arts. It is obvious that calico printing is in the abstract a topical dyeing; and much discrimination and taste are requisite in the contrivance of the pattern, its general design, and the colours in which it is exhibited. In this art the mordants, and sometimes the colours, are applied either by *blocks*, upon which the pattern is designed in relief, or by *copper plates*, which are engraved, or by *cylinders* or rollers. If the aluminous mordant be printed by one block and the iron mordant by another, and a mixture of the two by a third, and the piece thus prepared be then passed through a madder bath, and properly cleansed and bleached, the colour will only adhere to the mordanted places, and it will be red where the aluminous earth only has been applied, purple with the mixed mordant, and black with the iron; if the same three mordants be used with a decoction of quercitron bark, the resulting colours will be yellow, olive, and brown; and in this way a great variety of colours may be produced. Sometimes copperplate and block printing are combined; a fine running pattern being printed by the plate or cylinder over the whole surface, which serves as a groundwork, and upon which other figures are printed by blocks. Sometimes the mordant and colour are both applied at once by means of a block, and rendered fixed and permanent by exposing the goods for some time to steam. Some beautiful effects are also produced by printing the pattern upon a mordanted ground with some substance which will *resist* the colour, and so produce a white pattern upon a coloured ground. The same effect is sometimes brought about by *discharging* the colour by the topical application of certain bleaching materials.

DYKE, or DIKE. When a mass of unstratified or igneous rock, such as granite, trap, or lava, appears as if injected into rents and fissures in the stratified rock, so as to intersect the strata, it is called a *dyke*. *Dyke* is also the name given to a mound of earth, stones, or other materials, intended to prevent low land from being inundated by the sea, &c.; as the dykes of Holland.

DYNA'MICS (Gr. δυναμις, *force or power*), signifies literally the doctrine of force or power; but as force or power is known to us in no other way than by its effect, that is, by the *motion* which it produces in the body on which it acts, and is measured by that motion, dynamics may be defined to be the science which treats of the motion of bodies. It is, however, usually restricted to those circumstances of motion in which the moving bodies are at liberty to obey the impulses communicated to them; the opposite cases, or those in which the bodies, whether by external circumstances, or by their connection with one another, are not at liberty to obey the impulses given, being comprehended in the science of *mechanics*. Thus, the motion of a stone falling freely to the ground, or of a celestial body in its orbit, belongs to dynamics; while that of a body descending an inclined plane would properly belong to mechanics.

The theory of varied motions, and of the accelerating forces which produce them, is founded on two general laws: 1st, That all motion impressed on a body is by its nature uniform and rectilinear; and 2nd, That different motions impressed either simultaneously or successively on the same body, are compounded in such a manner that the body is found at every instant in the same point of space in which it would have been found in consequence of the combination of the motions had they existed separately. Thus, if a body be acted on by two forces at the same instant, one of which acting alone would cause it to move uniformly over A B, and the other acting alone would cause it to move over A C at right angles to A B in the same time; the velocity of the body in the one of these directions will not be changed by the force impelling it in the other. With regard to the first of these laws, it is evident that a body in motion, not subjected to the action of any new force, will continue to move in the prolongation of the straight line in which it moves at any given instant, since there is no reason why it should deviate from its rectilinear direction rather to one side than the other; but the uniformity of its motion cannot be asserted *à priori*: it is only by induction and experience that we come to be persuaded that the velocity with which any body is impressed will not diminish of itself, nor the body finally come to rest unless it is impeded by some external causes. The second law, which involves the theory of the *composition of forces*, has been demonstrated by several mathematicians, particularly Daniel Bernoulli, D'Alembert, Laplace in the *Mécanique Céleste*, and Poisson in his excellent *Traité de Mécanique*; but all these demonstrations are too difficult to be accounted elementary.

The science of dynamics is due entirely to the moderns, and its foundations were laid by the celebrated Galileo. Before him no one had considered the forces which act on bodies, excepting in the case of equilibrium; and although the acceleration of falling bodies, and the curvilinear motion of projectiles, had been attributed to the constant action of terrestrial gravity, no one had yet succeeded in determining the laws of these common phenomena. Galileo first made this important step in advance, and thereby opened a new and boundless field for the progress of mechanics. Huygens added to Galileo's theory of the acceleration of falling bodies the theories of the motion of pendulums and of centrifugal forces, and thus prepared the way for the great discovery of universal gravitation. In the hands of Newton mechanics became a new science; and the discovery of the infinitesimal calculus at length enabled geometers to express all the laws and circumstances of the motion of bodies by analytical equations. The investigation of the forces which produce the phenomena of the material world, or of the mutual action of the different parts of matter on each other, now form indeed the principal object of mathematical studies. The best systematic treatises on Dynamics are to be found in *Lagrange's Mécanique Analytique*, and *Poisson's Traité de Mécanique*. Of late years several valuable elementary treatises have appeared in our own language. See FORCE, MECHANICS, MOTION.

DYNAMOMETER. (Gr. δυναμις, *power*, and μετρον, *measure*.) An instrument for measuring power of any kind, as the strength of men and animals, the force of machinery, the magnifying power of a telescope, &c. An instrument for measuring animal force was invented by Mr. Graham many years ago, and afterwards improved by Desaguliers; but as it consisted of wooden works, it was too heavy and bulky to be conveniently used for ordinary purposes. Leroy, of the Academy of Sciences of Paris, proposed a dynamometer, which consisted merely of a tube of metal of ten or twelve inches in length, placed vertically on a stand, and containing a spring in its interior, which indicated by its compression the amount of the force applied. This instrument was in fact the same in principle as the common spring balance.

The most convenient dynamometer is that of Regnier, which is described in Cahier 5. of the *Journal de l'Ecole Polytechnique*. It consists of an elliptical steel spring of about 12 inches in circumference, and the force is applied either by pressing the two vertices of the axis minor against each other, or by drawing in opposite directions the two ends of the axis major. In both cases the sides of the spring are made to approach each other; and thus they move an index which marks the degree of approximation on a semicircular scale. By means of this machine the mean force is ascertained which a man can exert with the right hand, or with the left, or with both together, and in various positions of his body. Some interesting results relating to the average strength of men at different ages, and of different weights and sizes, have been deduced by M. Quetelet of Brussels from numerous experiments with this dynamometer. See STRENGTH OF ANIMALS.

DYNA'STIDÆ. (Gr. δυναστης, *a master*.) A family of beetles, including the giants of the Coleopterous order. They are remarkably powerful insects, excavating burrows in the earth and in putrescent timber, upon the latter of which they principally feed.

DY'NASTY. (Gr. δυνάστεια, from δυνάστης, *a lord or chieftain*.) A race or family of sovereigns in succession.

DYSÆSTHE'SIA. (Gr. δυς, an adverb signifying in composition *badness* or *difficulty*, and αισθανομαι, *I feel*.) Impaired sense of touch.

DY'SENTERY. (Gr. δυς, and εντερα, *bowels*.) A disease of the bowels, endemic in many climates in the autumnal months, and frequently arising from marsh miasma, bad diet, exhaustion and fatigue: its symptoms are loss of appetite, sickness, pain about the bowels, and a frequent ineffectual desire to evacuate their contents, which when passed are mucous, fetid, and bloody, with small indurated lumps. It is often accompanied by intermittent and remittent fever, especially in hot and damp countries. In this country dysentery is generally a mild disorder, and not infectious; and is commonly cured by gentle aperients, such as castor oil, or salts and manna, to cleanse the bowels, and opiates to allay irritation. The chronic symptoms which remain are treated with mild tonics, especially vegetable bitters, such as infusion of calumba, angustura, or cascarilla. The contagious dysentery of camps, attended by remittent or typhoid fever, is an alarming and fatal disease; its treatment requires much consideration and skill, and consists in judiciously meeting the various symptoms as they arise. Aperients, diaphoretics, and nauseants, succeeded by tonics, are leading remedies; and the febrile symptoms must be treated according to their inflammatory or putrid tendency.

DYSPE'PSIA. (Gr. δυς, and πεπτω, *I digest or concoct*.) Indigestion. This is a complaint from which few entirely escape, which assumes an infinite variety of shapes and symptoms, and which arises from many causes. In the higher ranks of society, and amongst the luxurious and opulent, it is a common consequence of over eating, or of indulgence in difficultly digestible or over-stimulating food, or of want of due exercise and general bodily and mental exertion. In others it results from mental anxiety and labour associated with a sedentary life; from the fatigues of business, or the influence of debilitating passions. In the lower orders it is the constant result of indulgence in spirituous liquors, combined in many instances with want of proper food, the means which ought to be applied to procuring it being disposed of in the gin shop.

The symptoms of dyspepsia vary, therefore, in the different grades of life. The epicure loses his relish for the most refined dishes, becomes bloated, plethoric, heavy, and perhaps apoplectic; the lady of fashion suffers from headaches, flatulence, occasional giddiness, and dimness of sight; she becomes indolent, capricious, and full of fancies, or, as the old physicians used to say, she has the *vapours*; the studious man feels the intensity of his mind blunted, loses his appetite, or at least all enjoyment of meals, sleeps ill, and dreams much, gets whimsical and discontented with himself and his friends, and becomes a *hypochondriac*; the lower classes at first take their glass of gin or of rum because they find it a cheap stimulant, little thinking of the misery they are laying up for future years; this stimulant soon becomes habitual, and they not only feel miserable and heartbroken without it, but the single glass soon loses its efficacy, and the dose must be gradually increased till they degenerate into regular tipplers, the aspect and characters of whom it were needless to describe, as they may be daily and hourly studied in those hells of temptation and iniquity, the gin shops of London, — where it is curious and instructive, but humiliating and alarming, to witness the various grades of mental and bodily disease in the men, women, and even children, who there immolate to Satan.

Complicated as are the symptoms of dyspepsia, and numerous as are the remedies and modes of treatment proposed for its relief or cure, they really resolve themselves into a few simple rules. In the majority of cases, *abstinence* is the first and most essential step: the epicure must abstain from the luxuries of the table, eat and drink with moderation, rise betimes, and use due exercise; the woman of fashion must revert to regular hours, that is,

the night and the day must be employed as intended by nature, and not in inverted order; the philosopher and the scholar must occasionally, and often frequently and assiduously, divest themselves of their mental labours, and resort to amusements and occupations of a more trivial character. Those among the lower orders who have once acquired the habit of dram drinking are incurable; for such is the depression of mind and body, and such the gnawing restlessness that want of the accustomed stimulus occasions, that without it they become miserable and inconsolable, and usually fall a sacrifice to mental or bodily disease, or to both combined: here, therefore, prevention is the only cure. The medical treatment of dyspepsia generally resolves itself into that of such of its particular symptoms or consequences as are most prominent; the inactivity of the bowels is to be opposed by proper aperients properly administered; the debilitated stomach to be strengthened by mild tonics, antacids, and stimulants; the mental symptoms often yield to the same treatment, and often require local depletion, or diffusible stimulants, such as ammonia and ether; and lastly, change of air, of scene, and of occupation are often indispensable, under which head sea bathing and courses of mineral waters may be included. The above observations are of course inapplicable to all cases of dyspepsia resulting from structural disease, which, though often an effect, is also a frequent cause of symptoms of indigestion; indeed, such are the sympathies of the stomach that it is apt to be affected by any aberration from health.

DYSPHA'GIA. (Gr. δυς, and φαγω, *I eat.*) Difficulty of swallowing. Paralysis, stricture of the œsophagus, enlarged tonsils, relaxed uvula, a debilitated state of the muscular coat of the pharynx and œsophagus, spasm of the organs concerned in deglutition, inflammation, are among some of the leading causes which occasion difficulty of swallowing; it is also an attendant upon hysteria, hypochondriasis, tetanus and trismus, and hydrophobia. The treatment will depend upon the prevailing cause, and is noticed under other articles.

DYSPNŒ'A. (Gr. δυς, and πνεω, *I breathe.*) Difficulty of breathing. This is generally a symptomatic affection, and commonly attends upon various morbid affections of the lungs, heart, &c. It occasionally happens that persons in full health are seized with an attack of difficulty of respiration; where this occurs in nervous irritable habits it generally goes off by perfect quiet, with the help of a little ether or ammonia; if in full habits, bleeding is sometimes requisite. Persons who are subject to these attacks should keep themselves as quiet and tranquil in body and mind as possible, and should avoid excess of food and wine, and even all stimulating diet. A recumbent posture, and sudden change of air, — as going out of a warm into a cold room, or into the open air, — will often relieve an accidental attack of dyspnœa.

DYSU'RIA. (Gr. δυς, and ουρον, *urine.*) Dysury. Difficulty in voiding the urine. A common symptom in cases of gravel, inflammation of the urinary organs, spasm, and stricture. The nature of the relief must depend upon the exciting cause.

E.

E. The fifth letter in the Hebrew alphabet, and in those derived from it. In the Latin language it is often interchanged with *i* and *o*; and in the Greek with *a*, *o*, and occasionally *u*. In most languages *e* admits of great variety in its pronunciation, and, in French and English particularly, surpasses every other letter of the alphabet in this quality: as a Latin numeral E signifies 250 —

E quoque ducentos et quinquaginta tenebit.

E. In Music, the third note or degree of the diatonic scale, corresponding to the *mi* of the French and Italians. In the bass clef it is that on the third space of the staff, in the tenor on the first space, in the counter tenor on the fourth line, and in the treble clef that on the first line.

EA'GLE. In Ornithology. *See* Aquila, Falconidæ.

Ea'gle. In History, the symbol of royalty; as being, according to Philostratus, the king of birds. Hence, in the Scriptures, a Chaldæan and Egyptian king are styled eagles. The eagle was borne as a standard by many nations of antiquity. The first who assumed it, according to Xenophon (*Anab.* i. 10.), were the Persians, from whom (in all probability through the medium of the Greeks) it was borrowed by the Romans at an early period of their history, but first adopted as their sole ensign in the consulate of C. Marius. (*Plin.* x. 4.) Previously to that period they had used as standards wolves, leopards, eagles, and other animals, indifferently, according to the humour of their generals. The Roman eagles were gold or silver figures in rilievo, about the size of a pigeon; and were borne on the tops of spears, with their wings displayed, and frequently with a thunderbolt in their talons. When the army marched the eagle was always visible to the legions; and when it encamped the eagle was always placed before their *prætorium* or tent of the general. The eagle on the summit of an ivory staff was also the symbol of the consular dignity. In modern times Napoleon caused the tricolor flag, which at the outbreak of the first French Revolution had become the standard of France, to be surmounted with an eagle; and thus constituted it the standard of the consular and imperial armies. From this circumstance, and from the almost unprecedented career of victory so long pursued by the French under this standard, the expression *eagles of Napoleon* is often used metaphorically to designate the *armies* under his command. After the battle of Waterloo the eagle was superseded in France by the fleur de lys, the ancient emblem of the Bourbon race. Eagles are frequently found on ancient coins and medals; where, according to Spanheim, they are emblematic of divinity and providence, but according to all other antiquaries of empire. They are most usually found on the medals of the Ptolemies of Egypt and the Selucidæ of Syria. An eagle, with the word *consecratio*, indicates the apotheosis of an emperor.

Eagle. In Heraldry, a bearing of frequent occurrence, and particularly assumed by sovereigns as the emblem of empire, from having been borne on the legionary standard of the ancient Romans. The eagle of Russia is *or*, with two heads displayed, sable, each ducally crowned of the field; the whole imperially crowned, beaked, and membered, gules. The eagle of Austria is also displayed with two heads; the Prussian eagle has one only. The Americans have adopted an eaglo of a peculiar species belonging to their continent as the device of the Union, which is impressed on their gold coins.

EA'GLE, BLACK. A Prussian order of knighthood, founded in 1701; united with the order of the Red Eagle, or order of Sincerity, instituted by the Margraves of Bayreuth.

EA'GLE STONE. A term applied by the old pharmaceutists to globular clay ironstone, which they called *lapis ætites.*

EA'GLE WOOD. A fragrant wood, used by the Asiatics for burning as incense. The Malayan name is *Agila*, whence the Portuguese name *Pao d'Agila.*

EAR. (Germ. ohr.) The external ear is formed of a pliant cartilage covered by a thin skin, and having appropriate nerves and muscles; its various cavities and projections have received distinctive names from the anatomist. The curved and irregular passage which leads to the inner ear is called the *meatus auditorius*, and

in the adult is more than an inch in length; it is lined with a peculiar secretion called *cerumen.* The *tympanum* separates the external from the internal ear; it is closed by a membrane called the *membrana tympani* or *drum of the ear*, upon the inner surface of which a nerve called the *chorda tympani* ramifies, and to the centre of which is affixed the process of a little hammer-shaped bone, called the *malleus*, and which, together with the *incus*, the *os orbiculare*, and the *stapes*, forms a chain of communication between the *tympanum* and the *fenestra ovalis:* these small bones are supplied with appropriate muscles. The *vestibule* is a small cavity in the petrous portion of the temporal bone, having a little spiral cavity called the *cochlea* connected with it, and three cylindrical cavities, or tubes, bent in a semicircular form, two of which are horizontal and one vertical. These cavities contain a liquid; and in them the auditory nerve, which proceeds from the fourth ventricle of the brain, ramifies and terminates. It is obvious that vibration of the tympanum, occasioned by undulations of the air, may be communicated through the bony chain above mentioned to the fluid in the vestibule, and thence to the acoustic nerve; but any further uses of this extraordinary and complicated mechanism are beyond our knowledge. In the annexed diagram *a* represents the external ear, *b* the external meatus, *c* the tympanum, *d* the malleus, *e* the incus, *f* the stapes, *g* the semicircular canals, and *h* the cochlea.

EA'RINGS. Small ropes fastened to cringles (loops) in the upper corners, and also to the *leeches* of sails, for the purpose of fixing the leeches of the sail to the yard. The first or head earings fix the corners of the sail permanently, the second are used only in reefing.

EARL. A title of dignity, derived from the Anglo-Saxons. It denoted at first any person of noble race (see *Palgrave's Rise of the E. Commonwealth*); and there seem to have remained in popular language traces of this ancient use of the name down to a late period. Afterwards some of the Saxon earls were hereditary, and some official governors of extensive districts. After the Conquest, the title of earl was used by the English to express the French title of count (in Latin comes); to which again the word graf (identical in origin with the English reeve) furnishes an equivalent in Germany. Hence the wife of an earl is still styled countess. In writings earlier than the age of Stephen, the Latin word consul is also used as synonymous. It has been supposed (and the explanation is supported by Mr. Cruise, *On Dignities*, p. 17.) that the dignity of an earl was originally annexed to the possession of a certain tract of land, and that there were three sorts of earldoms — one, when the dignity was annexed to the possession of a whole county with *jura regalia*, in which case the county was a county palatine, as Chester, Pembroke, and Durham; the second, where the earl had no possession of the county, and no advantage from it, but the third penny or third part of the sum arising from pleas in the county court; the third, where a tract of land was granted to hold as a county, "per servitium unius comitatus." But this is an opinion open to controversy; and it may be doubted whether there are any settled principles as to the creation or descent of earldoms earlier than the reign of Edward III., when they were granted by letters patent to the earl and the heirs of his body. Earldoms, like baronies, gradually became converted from territorial to merely titular honours. These two were the only titles in the English peerage, until the creation of the duchy of Cornwall in the 11th year of Edward III. (See *Nicolas's Synopsis of the Peerage of England*.)

EARL MA'RSHAL OF ENGLAND. One of the great officers of state, who regulates all great ceremonies, takes cognizance of all matters relating to honour, arms, and pedigree, and superintends the proclamation of peace or war. The court of chivalry, *curia militaris* (now almost forgotten), was formerly under his jurisdiction: he is still at the head of the herald's office, or college of arms. Camden, in his discourse concerning the etymology, antiquity, and office of earl marshal, alleges that it was first introduced in the reign of Richard II., who conferred it on Thomas Mowbray, Earl of Nottingham, his predecessors having been styled only *Marshals* of England. Various limitations have been made in the grants of this office from time to time; but it is now hereditary in the family of Howard, and enjoyed by its head, the Duke of Norfolk.

EA'RNEST (Lat. arrhæ; Fr. arrhes), in Law, is a part of the subject of a contract, as money or goods, transferred, in order by such delivery to pass the property in the whole, or in some other way to confirm the contract. By the Statute of Frauds, 29 C. 2. c. 3., no contract for sale of goods of the value of 10*l*. or more is good unless in writing, or unless such earnest be given or taken.

EA'R RINGS. (Germ. ohrringe.) Well-known ornaments worn by women, and sometimes by men, in all ages and countries. They have assumed an endless variety of forms; but consist generally at present of a simple ring, to which are attached pendant jewels, such as pearls, diamonds, or other precious stones. In the middle ages they were termed *pendants*, to which article the reader is referred for full information.

EARS. In Architecture. *See* CROSETTES.

EAR SHELL. *See* HALIOTIS.

EARTH. (Germ. erde, Lat. terra.) The name of the planet which we inhabit. It is the third in order from the sun, its orbit embracing the orbits of Mercury and Venus, but being within the orbits of all the other planets. The earth is endowed with a double motion: first, a motion of rotation about an axis passing through its centre; and secondly, a motion of revolution about the sun. It is the first of these motions which produces the phenomena of day and night, and the apparent diurnal revolution of the celestial bodies. The time in which the earth's rotation is performed is measured by the interval which elapses between two transits of the same fixed star over the meridian of any place; and this interval is always precisely the same, for astronomers have proved that it cannot have varied so much as three times the thousandth part of a second since the date of the first astronomical observation, that is to say, during the last two thousand years. It is called the *sidereal day*, and forms a perfectly uniform measure of time.

The revolution of the earth about the sun is performed in an elliptic orbit, which lies all in one plane, and has the sun in one of the foci. The eccentricity of the orbit, or the distance of the foci from the centre, is 0·01679 parts of the mean distance of the earth from the sun; so that if we take the mean distance for unity, the greatest distance of the sun is 1·01679, and the least 0·98321. The mean distance is nearly 95 millions of miles. The motion of the earth in its orbit is not uniform; being most rapid when it is at its *perihelion*, or point nearest the sun, and slowest at its *aphelion*, or greatest distance from the sun. This inequality of the angular motion of the earth about the sun gives rise to an inequality in the lengths of the *apparent* solar day, which is the interval of time between the successive transits of the sun over the same terrestrial meridian. If the earth moved uniformly in its orbit, accomplishing its annual revolution in the same time it does, the interval between any two consecutive transits of the sun over the same meridian would always be the same. This interval is called the *mean solar day*. The time in which the earth performs a revolution in its orbit, with respect to the fixed stars, or points in absolute space, is 365·2563612 mean solar days, or 365 days, 6 hours, 9 minutes, 9·6 seconds. This is called the *sidereal year*.

The plane which contains the earth's orbit is called the plane of the *ecliptic*. The axis of the earth's diurnal rotation is not perpendicular to the plane of the ecliptic, but makes with it an angle of 66° 32′ 4″; whence the *equator* of the earth is inclined to the ecliptic in an angle of 23° 27′ 56″. This inclination, which is called the *obliquity of the ecliptic*, gives rise to the phenomena of the seasons. In fact, as the two planes intersect always at the centre of the earth, it is evident that if, while the earth is carried round its orbit its axis of rotation remains always parallel to itself, the sun must rise above the equator during one half of the revolution, and fall below it during the other. Now this is what takes place: — the earth's axis of rotation preserves its parallelism, or points always towards the same star; and the sun in consequence at one period of the year is 23° 27′ 56″ to the north of the equator, and at the opposite season of the year is precisely the same distance to the south of it. The straight line formed by the intersection of the planes of the equator and ecliptic does not preserve the same position on the ecliptic; it has a slow motion *westward*, or contrary to the order of the signs, and retreats at the rate of 50·1″ annually; so that when the sun appears to return to the equator the sidereal revolution has not been quite completed: there remains an arc of 50·1″. The time in which the sun, or, to speak correctly, the earth, describes this arc is 20 minutes, 19·9 seconds; consequently the periodical return of the seasons is shorter by 20 m. 19·9 sec. than the true sidereal revolution of the earth round the sun. But the revolution of the seasons forms what is called the *equinoctial* or *tropical* year; which, therefore, is equal to 365·2422414 mean solar days; or 365 d. 5 h. 48 m. 49·7 sec.

The figure of the earth is that of an oblate spheroid of revolution, the axis of the poles being to the diameter of the equator in the ratio of 301 to 302. The equatorial diameter is nearly 7925 English miles, and the polar diameter about 7898 miles. (*See* DEGREE.) The mean radius of the earth is 3956 miles. Hence, supposing the earth to be a sphere, its whole surface would contain about 196,663,000 square miles.

The knowledge of the true figure and dimensions of the earth has been obtained by a combination of the results of mathematical theory with the actual measurement of degrees, and observations of the length of the seconds' pendulum at different places on its surface. As a great portion of the surface of the earth is covered by the sea, the general figure must be such as will satisfy the conditions of hydrostatic equilibrum. If the earth were fluid, and had no motion of rotation, its figure would be that of a sphere; but the rotation gives rise to a force which tends to cause every particle to recede from the axis, and which is proportional to the distance of the particle from the axis. Hence the attraction of the whole mass on any particle is to a certain extent counteracted by the centrifugal force of rotation, and the attraction is most diminished at the equatorial parts, where the distance from the axis is the greatest. Hence, in order that equilibrium may be restored, an accumulation of matter must take place round the equator, so that the mass will bulge out in that region, and become flattened at the poles. These theoretical considerations only render the spheroidal form of the earth probable; but they are fully confirmed by experiments of different kinds. If the earth is an oblate spheroid of revolution, the force of gravity at its surface must increase on going from the equator towards the poles; and the increase must be exactly proportional to that of the square of the sine of the latitude. Now it has been found by swinging an invariable pendulum at a great number of places, that the increase of gravity from the equator to the poles does follow this law. Anomalous results, indeed, appear; but they are only such as might be expected *à priori* from local irregularities of the surface, which, however, bear a much smaller proportion to the whole mass of the earth than the protuberances on the skin of an orange to its diameter. Another method of determining the exact form of the earth is by measuring the length of degrees of the meridian. Supposing the meridian to be an ellipse, the degrees of latitude must

become longer and longer as we recede from the equator, and the augmentation must be proportioned to the square of the sine of the latitude. This has likewise been found, by numerous measurements undertaken for the purpose, to hold true; so that theory and experiment fully concur in proving the general form of the earth to be that of an oblate spheroid of revolution.

On account of the large proportion of the earth's surface which is covered with water, and the comparatively small height to which the dry land rises above the level, it is evident that the figure of the earth cannot deviate much from that which is required for the hydrostatic equilibrium. It is computed that the proportion of water to land over the whole surface is as 2 to 1; that is to say, two thirds of the whole surface is covered with water, the surface of which must be in equilibrium. The altitude of the highest mountains on the earth above the level of the sea is supposed to be about 26,000 feet, or nearly five miles. But the mean radius of the earth, as we have already stated, is nearly 4000 miles; consequently the greatest superficial inequalities do not exceed the 800th part of the radius. In general they amount to but a small part of this quantity.

The *mass* of the earth compared with that of the sun is nearly as 1 to 355,000. Its mean density, which has been ascertained by observing the effect of mountains in deflecting the plumb-line from the perpendicular (ATTRACTION OF MOUNTAINS), and by experiments on the attraction of leaden balls, is to that of water as $5\frac{1}{2}$ to 1. The centrifugal force at the equator is to that of gravity as ·00346 to 1; and the force of gravity there is such that bodies fall through $16\frac{1}{12}$ feet in the first second of time. If the rotation of the earth were 17 times more rapid, the centrifugal force at the equator would be just equal to the attractive force, and bodies would have no weight.

From a knowledge of the form of the earth, and of its mean density, we are enabled to form some conjecture respecting its interior constitution. Newton demonstrated that if the earth were a homogeneous mass, or of equal density throughout, the ratio of its polar to its equatorial diameter would be that of 230 to 231; that is, the ellipticity would be $= \frac{1}{231}$. But the ellipticity found from the actual measurement of degrees is, as we have seen, considerably less than this fraction; consequently the earth is not homogeneous. Huygens, on the other hand, adopting the hypothesis that the density increases regularly from the surface to the centre, at which point it is infinite, found the ratio of the diameters to be that of 578 to 579. The true compression considerably exceeds that given by this ratio; and therefore, since it lies between the results of the two hypotheses, we infer that the density increases towards the centre, but that the density at the centre is not infinitely great.

Considering that the mean density of the whole earth is only about five and a half times that of water, and that the materials of which the crust of the earth is composed are all compressible in a greater or less degree, so that even at no very great depth the density of the different substances must be greatly increased by the mere pressure of the superincumbent materials, some philosophers have supposed that the effects of pressure must be counterbalanced by the expansive force of a great heat subsisting in the interior of the earth; and others that the earth is not solid, but merely a hollow shell of inconsiderable thickness. It has been calculated that at the depth of 35 miles, air, subjected to the pressure of a column of matter of the mean density of that at the surface of the earth, would acquire the density of water; that at the depth of 173 miles, water itself, which is eminently incompressible, would acquire the density of marble; and at the centre, marble would have a density 119 times greater than at the surface. But the comparatively small mean density of the mass proves that none of these effects take place. The hypothesis which supposes the earth to be hollow in the interior, is contrary to every analogy; and as it can be demonstrated from astronomical considerations that the density must increase in descending from the surface to a depth equal at least to one fourth of the radius, it is infinitely probable that this density continues to increase even to the centre; but that a very high temperature exists in the interior of the earth, in consequence of which the materials resist the effects of the condensation due to the pressure to which they are subjected. The principal arguments which have been brought forward to prove the high temperature of the interior parts of the earth, or the central heat, are drawn from the following circumstances: —

1. The form of the earth, nearly spherical, and flattened at the poles of rotation, together with the regular disposition of the materials about the centre in elliptic layers, proves that it must have originally existed in a fluid, if not an aëriform state; so that the constituent molecules must have had free liberty to obey the forces arising from their mutual attraction and from the position of the whole mass, and arrange themselves in the position of equilibrium. But there is no other agent than heat to which we can attribute the fusion of such substances as compose the greater part of the exterior crust of the earth. 2. The phenomena of volcanos, hot springs, and earthquakes, receive a very simple explanation on the hypothesis that the nucleus of the earth still remains in a state of fusion, and that the consolidation of the exterior crust still proceeds, though at an extremely slow rate. 3. The fact, which now appears to be fully established, that a sensible increase of temperature takes place as we descend from the surface (in deep mines for example), after passing the depth at which the influence of the solar heat ceases to be felt, furnishes a direct proof of a very high temperature in the interior of the earth. Much uncertainty exists as to the rate at which this increase takes place; but the mean results of a number of experiments made in the deep mines of Cornwall, and different parts of France and Germany, gives an increase of 1° of Fahrenheit's thermometer for every 15 yards of vertical descent, after passing the stratum of constant temperature. Admitting this rate of increase, and supposing it to be continued to the centre, the intensity of heat at the centre will be expressed by 3500° of Wedgewood's pyrometer. The temperature of 100° of Wedgewood, which is sufficient to fuse the lavas and the greater part of the known rocks, would be found at the depth of 125 miles; but M. Cordier, who, in the *Memoirs of the Royal Academy of Sciences of Paris* (volume for 1827), has collected a great number of facts relative to this subject, is of opinion that the phenomena warrant the conclusion that the mean thickness of the solid crust of the earth does not exceed 60 miles.

In order to explain the primitive fluidity of the earth, which it is necessary to admit in consequence of its figure and the law of the diminution of gravity from the poles to the equator, a different hypothesis has been proposed, and had numerous partisans. It consists in supposing a primitive dissolution of all the materials of the earth in a liquid, such as water. But if we consider that the fluidity of all bodies, even of liquids, is an effect of heat; that it is necessary to suppose not merely a partial fusion of the exterior crust, but of the whole mass of the earth; and that the weight of all the water on the globe does not probably amount to a 50-thousandth part of that of the solid materials, the insufficiency of this hypothesis will be apparent.

In whatever manner the earth may have taken its existing form, there are abundant proofs that its surface has been the theatre of many great revolutions. The masses of sand and gravel, and beds of limestone composed of shells and corals, which are found in the interior of continents, and even to the summits of the highest mountains, plainly show that the present land was once immersed deep under the waters of the ocean. The remains of animals and plants belonging to tropical countries, found in the highest latitudes, indicate an entirely different disposition of climates from that which now exists. The appearances of the mineral strata, twisted, and dislocated, and broken asunder, also afford undeniable evidence that the changes which have taken place on the surface of the earth have not all been brought about by the silent action of the causes which we see in daily operation, but by the operation of some violent force which has shaken the globe to its very centre. Whether these convulsions have been produced by an internal or external force; by the action of a central heat heaving up the solid crust of the earth, and raising mountains from the depths of the ocean; or by the collision of a comet, changing the axis of the earth's diurnal rotation, destroying the pre-existing equilibrium, and carrying the waters towards the new equator, — can never be any thing more than matter of speculation and conjecture. All that science makes known on the subject is, that since the time of the first recorded astronomical observations, that is to say, during the last two thousand years, the poles of the earth have been at precisely the same points on its surface as at the present day. *See* GEOGRAHY, PLANET.

EARTH. In Agriculture, earths are distinguished from soils by their being without organized matter in their composition. Though scarcely any such earths are found on or near the ground's surface, yet the distinction is of use in speaking of soils. Thus we say a soil, the basis of which is earth, of sandstone, or of chalk, &c.

EARTH. In Chemistry this term is applied to certain insoluble metallic oxides of abundant occurrence in rocks and soils, such as silica and alumina. Lime, magnesia, baryta, and strontia have been called *alkaline* earths, their action on vegetable colours being similar to that of the alkalis.

EARTHENWARE. *See* POTTERY.

EARTH NUTS, are various subterranean substances produced by plants. In England the name is given to the nut of *Conopodium flexuosum*, an umbelliferous plant; in Egypt to the round tuber of *Cyperus rotundus*, and other species of the same genus; in China to the subterranean pods of *Arachis hypogæa*, a leguminous plant; and in other countries to similar pods produced by the genera *Voandzeia*, *Amphicarpæa*, &c.: or to the small tubers of Cyperaceous plants.

EARTHQUAKE. One of the most formidable phenomena of nature. As the name implies, it consists of a vio-

lent agitation of the earth, accompanied by various other phenomena more or less singular and destructive in their effects, but by no means uniform in character, as the following enumeration of concomitant circumstances, gleaned from the accounts of various earthquakes that have occurred in ancient and modern times, will sufficiently evince. Earthquakes are usually preceded by a general stillness in the air, and an unnatural agitation of the waters of the ocean and of lakes. The shock comes on with a deep rumbling noise, like that of a carriage over a rough pavement, or with a tremendous explosion resembling a discharge of artillery or the bursting of a thunder cloud; and sometimes heaves the ground perpendicularly upwards, and sometimes rolls it from side to side. The single shocks of an earthquake seldom last longer than a minute, but they frequently follow one another at short intervals for a considerable length of time. During these shocks large chasms are made in the ground, from which sometimes smoke and flames, but more frequently stones and torrents of water, are discharged. In violent earthquakes, these chasms are sometimes so extensive as to overwhelm whole cities at once. In consequence of these shocks, also, whole islands are frequently sunk and new ones raised; the course of rivers is changed; seas overflow the land, forming gulfs, bays, and straits; sometimes disrupting the land into islands, and sometimes joining them to the continent.

There is no portion of the earth's surface, whether it be land or water, that is not more or less subject to earthquakes; and records of their destructive effects have been transmitted to us through every age. The first earthquake particularly worthy of notice was that which, in A.D. 63, destroyed Herculaneum and Pompeii. In the fourth and fifth centuries, some of the most civilized parts of the world were almost desolated by these awful visitations. Thrace, Syria, and Asia Minor, according to contemporary historians, suffered most severely. On the 26th of January, A.D. 447, subterranean thunders were heard from the Black to the Red Sea, and the earth was convulsed, without intermission, for the space of six months; and in Phrygia, many cities and large tracts of ground were swallowed up. On the 30th of May, A.D. 205, the city of Antioch was overwhelmed by a dreadful earthquake, and 250,000 of its inhabitants are said to have been crushed in its ruins.

In the year 1346, Asia Minor and Egypt were violently shaken; and in the following year severe earthquakes were experienced in Cyprus, Greece, and Italy.

In 1692, the island of Jamaica was visited by a terrible earthquake, in which enormous masses of earth were detached from the Blue Mountains; and vast quantities of timber, hurled from their flanks, covered the adjacent sea, like floating islands. It was during this earthquake that the city of Port Royal, with a large tract of adjacent land, sunk instantaneously into the sea. In the following year great earthquakes occurred in Sicily, which destroyed Catania and 140 other towns and villages, with 100,000 of their inhabitants.

Since the records of history, there have been no earthquakes equal in intensity to those which ravaged different parts of the world in the eighteenth century. Passing over the convulsion which in 1746 nearly laid waste Lower Peru, and those by which in 1750 the ancient town of Concepcion in Chili was totally destroyed, we come to 1755, when the city of Lisbon was almost wholly destroyed by one of the most destructive earthquakes which ever occurred in Europe. It continued only six minutes; but such was the violence of the convulsion, that in that short space upwards of 60,000 persons are said to have perished. The phenomena that accompanied it were no less striking. The sea first retired and laid the bar dry; it then rolled in, rising fifty feet or more above its ordinary level. The largest mountains in Portugal were impetuously shaken from their very foundations; and some of them opened at their summits, which were split and rent in a wonderful manner, huge masses of them being thrown down into the subjacent valleys. But the most remarkable circumstance which occurred at Lisbon during this catastrophe was the entire subsidence of the new quay, called Cays de Prada, to which an immense concourse of people had fled for safety from the falling ruins. From this hideous abyss, into which the quay sunk, not one of the dead bodies ever floated to the surface; and on the spot there is now water to the depth of 100 fathoms. This earthquake excited great attention from the incredibly great extent at which contemporary shocks were experienced. The violence of the shocks, which were accompanied by a terrific subterranean noise, like the loudest thunder, was chiefly felt in Portugal, Spain, and northern Africa; but the effects of the earthquake were perceived in almost all the countries of continental Europe, and were even experienced in the West Indies, and on the Lake Ontario in North America. Ships at sea were affected by the shocks as if they had struck on rocks; and even at some of the Scottish lakes, Loch Lomond in particular, the water, without the least apparent cause, rose to the perpendicular height of two feet four inches against its banks, and then subsided below its usual level. During the next twenty years, various earthquakes occurred in different parts of the world, attended with more or less destructive consequences. In 1759, Syria was agitated by violent earthquakes, the shocks of which were protracted for three months, throughout a space of 10,000 square leagues, and levelled to the ground Accon, Saphat, Balbeck, Damascus, Sidon, Tripoli, and many other places. In each of these places many thousands of the inhabitants perished; and in the valley of Balbeck alone, 20,000 men are said to have been victims to the convulsion. In 1766, the island of Trinidad and great part of Columbia were violently agitated by earthquakes. In 1772, the lofty volcano of Papandayang, the highest mountain in Java, disappeared, and a circumjacent area, fifteen miles by six, was swallowed up. In 1783, the north-eastern part of Sicily and the southern portion of of Calabria were convulsed by violent and oft-repeated shocks, which overthrew the town of Messina, and killed many thousands of its inhabitants, as well as many persons in Calabria. In the same year the islands of Japan, Java in 1786, Sicily and the Caraccas in 1790, Quebec in 1791, and the Antilles and Peru in 1797, were violently agitated by convulsions of this kind.

Since the commencement of the present century, various earthquakes have occurred both in the Old and New World. In 1811, violent earthquakes shook the valley of the Mississippi, by which lakes of considerable extent disappeared, and new ones were formed. In 1812, Caraccas was destroyed, and upwards of 12,000 of its inhabitants buried in the ruins. In 1815 the town of Tombora, in the island of Sumbawa, was completely destroyed by an earthquake, which extended throughout an area 100 miles in diameter, and destroyed 12,000 persons. In 1819, a violent earthquake occurred at Cutch, in the Delta of the Indus, by which, among other disastrous consequences, the principal town, Bhoog, was converted into a heap of ruins. In 1822, Aleppo was destroyed by an earthquake. In the same year Chili was visited by a most destructive earthquake, from which the coast for 100 miles is stated to have sustained an elevation of from two to four feet, while about a mile inland from Valparaiso it was raised from six to seven feet. In 1827, Popayan and Bogota suffered severely from earthquakes, during which vast fissures opened in the elevated plains around the latter city. In 1835, the town of Concepcion, in Chili, was entirely demolished by an earthquake. In 1837, the countries along the eastern extremity of the Mediterranean, especially Syria, were violently agitated by an earthquake, which caused great damage to the towns of Damascus, Acre, Tyre, and Sidon, and entirely destroyed Tiberias and Safet. Such are some of the most violent earthquakes that have occurred within the period of authentic history. The reader will find in *Poggendorf's Annalen* lists of the different earthquakes that have taken place within the last twenty years; and from these it will be observed that scarcely a month elapses without being signalized by one or many convulsions in some part of the globe. Shocks of earthquakes have at different times been felt in various parts of Britain, and more particularly in Scotland; but they have all fortunately been so insignificant, compared to those which have been experienced in other countries, that we shall refrain from entering into any details respecting them.

But though history supplies us with so large a catalogue of well-authenticated earthquakes, it is surprising that so little was done by the ancients either in investigating their causes or noticing their effects. It is only within the last century and a half, says Mr. Lyell, since Hooke first promulgated his views respecting the connection between geological phenomena and earthquakes, that the permanent changes effected by these convulsions have excited attention. Before that time the narrative of the historian was almost exclusively confined to the number of human beings who perished, the number of cities laid in ruins, the value of property destroyed, or certain atmospheric appearances which dazzled or terrified the observers. The creation of a new lake, the engulphing of a city, or the raising of a new island, are sometimes, it is true, adverted to, as being too obvious or of too much geographical interest to be passed over in silence. But no researches were made expressly with the view of ascertaining the amount of depression or elevation of the ground, or any particular alterations in the relative position of sea and land; and very little distinction was made between the raising of soil by volcanic ejections, and the upheaving of it by forces acting below. The same remark applies to a very large proportion of modern accounts; and how much reason we have to regret this deficiency of information appears from this, that in every instance where a spirit of scientific inquiry has animated the eye-witnesses of these events, facts calculated to throw light on former modifications of the earth's structure are recorded. Upon these questions, however, it is not our present intention to enter, as they will be more appropriately treated of under the heads GEOLOGY

and VOLCANO; to which articles we must refer the reader for an account of the various theories that have been maintained in regard to the origin or cause of earthquakes, as well as for a view of the grand permanent changes which these convulsions have produced on the surface and in the internal structure of the earth's crust. See *Bakewell's Introduction to Geology; Lyell's Geology; Traill's Physical Geography;* and *Phillips's Geology.*

EA'RWIG. *See* DERMAPTERA FORFICULA.

EA'SEL. (Germ. esel, *an ass.*) In Painting, a wooden frame used for supporting a picture during the progress of its execution.

EA'SEL PIECES. In Painting, pictures whose size is small enough to be painted on an easel.

EA'SEMENT. In Law, a convenience which one man has of another, his neighbour, by grant or prescription. Easements were included in the Roman law under the title servitutes; such are a way over the lands of another, or a water-course.

EAST. (Germ. Ost.) The point of the horizon at which the sun rises at the time of the equinoxes; or the point determined by a perpendicular to the meridian drawn towards the quarter of sunrise. The *east* is one of the four *cardinal points* of the compass.

EA'STER. (Germ. Ostern.) The festival which is held in commemoration of our Lord's resurrection. The term seems to be derived from a Saxon word signifying *rising.*

The Jews celebrated their passover, in conformity with the directions given them by Moses, on the 14th day of the month Nisan, being the lunar month of which the 14th day either falls on, or next follows, the day of the vernal equinox. In the year of our Lord's crucifixion this fell on a Friday: the resurrection, therefore, took place on the first day of the next week, which from thence is denominated the Lord's day. The primitive Christians in their desire to celebrate this anniversary fell into two different systems. The Western churches observed the nearest Sunday to the full moon of Nisan, taking no account of the day on which the passover would be celebrated. The Asiatics, on the other hand, following the Jewish calendar, adopted the 14th of Nisan upon which to commemorate the crucifixion, and observed the festival of Easter on the third day following, upon whatever day of the week that might fall; hence they obtained the name of Quartodecimantes: the former appealed to the authority of St. Peter and St. Paul, the latter to that of St. John.

The dispute which took place upon this point in the 2d and 3d centuries of our era is remarkable, as connected with perhaps the first event which can be brought to bear upon the question of the primacy of the Roman bishop; and it is the more interesting as both parties are accustomed to claim it as a testimony in favour of their own views. Victor, bishop of Rome, wrote an imperious letter to the Asiatic bishops, requiring their conformity to the Western rule; which was answered by Polycrates, bishop of Ephesus, in the name of the rest, expressing their resolution to maintain the custom handed down to them by their ancestors. The Roman bishop thereupon broke off communion with them; but he was rebuked by Irenæus of Lyons, and it was agreed by his mediation that each party should retain its customs. Such continued to be the practice till the time of Constantine, when the Council of Nice determined the matter by the following canons:—

1. Easter must be celebrated on a Sunday.
2. This Sunday must *follow* the 14th day of the paschal moon; so that if the 14th day of the paschal moon falls on a Sunday, then Easter must be celebrated on the Sunday following.
3. The paschal moon is that moon of which the 14th day either falls on, or next follows, the day of the vernal equinox.
4. The 21st day of March is to be accounted the day of the vernal equinox.

The new moons, it is necessary to observe, are those of the ecclesiastical calendar, which are determined arbitrarily (by the lunar cycle in the Julian calendar, and by means of the table of epacts in the Gregorian); so that the above rules define Easter without ambiguity. The new moons of the calendar are in general one or two days, sometimes even three days, *later* than the astronomical or true new moons; and the 14th day of the moon is accounted the full moon, although the opposition takes place more frequently on the 16th day. *See* CALENDAR, EPACT.

EAST INDIA COMPANY. A famous joint stock association originally established to carry on the trade between this country and the East Indies, or rather with the countries to the eastward of the Cape of Good Hope. It was constituted by royal charter in 1600, and continued, notwithstanding repeated efforts to open the trade, to enjoy the exclusive privileges originally conceded till 1688. At that period the power of the crown to restrain the freedom of trade without the sanction of parliament having been denied, a rival association obtained an act of parliament in its favour; but after a variety of negotiations, which it is unnecessary to specify, the two corporations were joined in 1702 under the name of "The United Company of Merchants trading to the East Indies;" an appellation which has been continued to the present day. In 1708 the United Company was secured by parliament in the exclusive privilege of trading to all places eastward of the Cape of Good Hope to the Straits of Magellan; and this privilege, with some modifications, was confirmed and prolonged by successive acts of parliament down to 1814. By the act 53 Geo. 3. c. 133., passed in 1813, the East India Company's charter was renewed for twenty years; but it then received some important modifications, by which a restricted intercourse was permitted to all British merchants with the whole of the Company's Indian possessions; the monopoly of the trade between England and China being, however, retained in the hands of the East India Company. These concessions paved the way for the act of 1833, by which, though the Company's charter was prolonged till 1854, not only was the monopoly of the China trade abolished, but an end wholly put to the Company's original character of a commercial association.

But it is not as a commercial association so much as a great territorial power, that the East India Company has become so distinguished. The first establishments of the English in India, as of other European nations, arose out of the alleged necessity of providing armed factories or strongholds, where the adventurers might warehouse their goods, and reside in safety for the purpose of carrying on their intercourse with the natives; but the factories speedily degenerated into fortifications, and the garrisons into armies. For a while the power of the English and French was pretty nearly balanced in India; but the talents and victories of the famous Lord Clive gave us a decided superiority over every competitor, foreign or native, and extended our sway over some of the largest and finest portions of the Mogul empire. The policy of Clive, whether it were really approved by the succeeding governors-general of our Indian dominions, or were forced upon them by necessity, has, some few short intervals excepted, been steadily followed up; and with such signal success, that our Indian empire comprizes at present the whole of Hindostan from the Himalaya Mountains to Cape Comorin, with a population of above 120 millions!

The most exaggerated accounts have been at all times current in Europe of the extraordinary wealth of India, and of the importance of the commerce with that part of the world. After the victories of Lord Clive, the most sanguine expectations began to be entertained, not only of a vast increase of trade with India, but that we should draw from her an immense amount of surplus revenue, or tribute. Perhaps it is not going too far to say that these expectations have been entirely disappointed. Great abuses existed in the government of the Bengal provinces when conquered by Clive; the servants of the East India Company making large fortunes by the oppression of the natives and the ruin of the country. But, notwithstanding the eradication of the abuses in question, the immense additions that have since been made to our empire, and the oppressive taxes laid on the natives, it is not very clear that England has hitherto derived any direct revenue from India. The distance of the country, and the totally dissimilar language and customs of the people, are very great obstacles to our governing it with the economy necessary to make it yield any considerable amount of surplus revenue. The East India Company always contended that the profits made by their monopoly of the China trade were necessary to enable them to conduct the government of India. But, though there are strong grounds on which to impeach the accuracy of this statement, still it is abundantly clear that the surplus revenue we have derived from India, supposing there has been any such, has been comparatively inconsiderable; and quite trifling, indeed, compared with our own anticipations, and with the notions entertained by others of its magnitude.

Until 1815 and 1816, when the continued fall in the price of cotton goods, caused by the astonishing discoveries and inventions of Arkwright, and the other founders and improvers of the cotton manufacture, enabled us to export cottons to India and to undersell the natives, the trade between this country and India was of the most limited description. Previously to the opening of the trade in 1813-14 the total amount of the exports of all sorts, including the important item of military stores, by the East India Company and by private traders in the Company's ships, did not amount to 1,400,000*l.* a year; and even on this a considerable loss is believed to have been incurred! But such has been the increased demand for British cottons, that the value of those exported to India amounts, at present, to above 2,500,000*l.* a year, and the whole of our exports to her to near 4,000,000*l.* Even this, considering the vast extent of India, is but a trifling export; it is, in fact, less than half the amount of our exports to the United States.

The restricted amount of our commerce with India may, perhaps, be in some degree ascribed to its having

been so long monopolized by the East India Company. But this will not explain the small surplus of Indian revenue; for, however ill fitted to serve as a commercial engine, the East India Company has governed India with singular discretion; and has made the most praiseworthy efforts to enforce economy in all departments of the administration, and to appoint the best men to all situations of power and emolument in that country. The patronage of India has always been less jobbed and abused than that of England; and there are few governments that have made more vigorous exertions to repress abuse, and to protect the rights of their subjects.

Under the act 3 & 4 W. 4. c. 85., to which we have alluded above, for continuing the charter till 1854, the functions of the East India Company have been rendered wholly political. She is to continue to govern India, with the concurrence and under the supervision of the Board of Control (*see* Control, Board of) nearly on the plan laid down in Mr. Pitt's act, in 1784, by which the Board of Control was constituted. All the real and personal property belonging to the company on the 22d of April, 1834, is vested in the crown, and is to be held or managed by the company in trust for the same; subject, of course, to all claims, debts, contracts, &c. already in existence, or that may hereafter be brought into existence by competent authority. The company's debts and liabilities are all charged on India. The dividend, which is to continue at 10½ per cent., is to be paid in England out of the revenues of India; and provision is made for the establishment of a *security fund* for its discharge. The dividend may be redeemed by parliament, on payment of 200*l*. for 100*l*. stock, any time after April, 1874; but it is provided, in the event of the company being deprived of the government of India in 1854, that they may claim redemption of the dividend any time thereafter upon 3 years' notice. (3 & 4 *Will*. 4. c. 85.)

Company's Stock—forms a capital of 6,000,000*l*., into which all persons, natives or foreigners, males or females, bodies politic or corporate (the Governor and Company of the Bank of England only excepted), are at liberty to purchase, without limitation of amount. Since 1793, the dividends have been 10½ per cent., to which they are limited by the late act.

General Courts.— The proprietors in general court assembled are empowered to enact by-laws, and in other respects are competent to the complete investigation, regulation, and control of every branch of the company's concerns; but, for the more prompt despatch of business, the executive detail is vested in a court of directors. A general court is required to be held once in the months of March, June, September, and December, in each year. No one can be present at a general court unless possessed of 500*l*. stock; nor can any person vote upon the determination of any question who has not been in possession of 1000*l*. stock for the preceding 12 months, unless such stock have been obtained by bequest or marriage. Persons possessed of 1000*l*. stock are empowered to give a single vote; 3000*l*. are a qualification for two votes; 6000*l*. for three votes; and 10,000*l*. and upwards for four votes. There were 2003 proprietors on the company's books in 1825; of these, 1494 were qualified to give single votes; 392, two votes; 69, three votes; and 48, four votes. Upon any special occasion, 9 proprietors, duly qualified by the possession of 1000*l*. stock, may, by a requisition in writing to the court of directors, call a general court; which the directors are required to summon within 10 days, or, in default, the proprietors may call such court by notice affixed upon the Royal Exchange. In all such courts the questions are decided by a majority of voices; in case of an equality, the determination must be by the treasurer drawing a lot. Nine proprietors may, by a requisition in writing, demand a ballot upon any question, which shall not be taken within 24 hours after the breaking up of the general court.

Court of Directors.— The court of directors is composed of 24 members, chosen from among the proprietors, each of whom must be possessed of 2000*l*. stock; nor can any director, after being chosen, act longer than while he continues to hold stock. Of these, 6 are chosen on the second Wednesday in April in each year, to serve for 4 years, in the room of 6 who have completed such service. After an interval of 12 months, those who had gone out by rotation are eligible to be re-elected for the ensuing 4 years. Formerly, no person who had been in the company's civil or military service in India was eligible to be elected a director until he had been a resident in England two years after quitting the service; but this condition no longer exists; and all civil or military servants of the company in India, supposing they are otherwise eligible, may be chosen directors immediately on their return to England, provided they have no unsettled accounts with the company; if so, they are ineligible for 2 years after their return, unless their accounts be sooner settled. (3 & 4 *Will*. 4. c. 85. § 28.) The directors choose annually, from amongst themselves, a chairman and a deputy-chairman. They are required by by-laws to meet once in every week at least; but they frequently meet oftener, as occasion requires. Not less than 13 can form a court. Their determinations are guided by a majority. In case of an equality, the question must be decided by the drawing of a lot by the treasurer: upon all questions of importance, the sense of the court is taken by ballot. The company's officers, both at home and abroad, receive their appointments immediately from the court, to whom they are responsible for the due and faithful discharge of the trust reposed in them. The patronage is, nevertheless, so arranged, as that each member of the court separately participates therein.

Secret Committee. — The principal powers of the court of directors are vested in a secret committee, forming a sort of cabinet or privy council. All communications of a confidential or delicate nature between the Board of Control and the company are submitted, in the first instance at least, to the consideration of this committee; and the directions of the board, as to political affairs, may be transmitted direct to India, through the committee, without being seen by the other directors. The secret committee is appointed by the court of directors, and its members are sworn to secrecy.

The territorial possessions of the East India Company are divided into the three presidencies of Bengal, Madras, and Bombay, at each of which the executive government is administered by a governor and three councillors, the governor of the Bengal presidency being at the same time governor-general of India. In their several presidencies, the governors and their councillors possess the privilege of enacting and enforcing laws; subject, however, in some cases, to the concurrence of the supreme court of judicature, and, in all cases, to the approval of the court of directors and the board of control.

We copy the following tables of Revenue, &c. from Mr. M'Culloch's *Statistics*, vol. ii. p. 519.

An Account of the Total Annual Revenues and Charges of the British Possessions in India under the East India Company, from 1809-10 to 1829-30; showing also the Nett Charge of Bencoolen, Prince of Wales Island, and St. Helena, the Interest paid on account of Debts in India, and the Amount of Territorial Charges paid in England. —(*Parl. Papers*, No. 22. Sess. 1830, and No. 306. Sess. 1833.)

Years.	Total Gross Revenues of India.	Total Charges in India.	Nett Charge of Bencoolen, &c.	Interest on Debts.	Territorial Charges paid in England.			General Result.

N.B. The Company realized in 1834-35 the sum of 10,679,223*l.* by the sale of commercial assets. The debts of the Company in India on the 30th of April, 1834, amounted to 34,463,483*l.*, bearing an interest of 1,754,545*l.* a year. — (*Parl. Paper*, No. 380. Sess. 1836.)

We subjoin the following table, exhibiting the extent and population of India, which we copy from the second edition of Mr. Hamilton's *Indian Gazetteer*. Some later accounts have been published as to the population of particular provinces; but we believe that this is the most accurate statement that has hitherto been framed, embracing the whole country.

	British Square Miles.	Population.
Bengal, Bahar, and Benares - - - - -	162,000	39,000,000
Additions in Hindostan since A. D. 1765 - - - - -	148,000	18,000,000
Gurwal, Kumoon, and the tract between the Sutuleje and Jumna - -	18,000	500,000
Total under the Bengal presidency - - - -	328,000	57,500,000
Under the Madras presidency - - - - -	154,000	15,000,000
Under the Bombay presidency - - - - -	11,000	2,500,000
Territories in the Deccan, &c., acquired since 1815, consisting of the Peishwa's dominions, &c., and since mostly attached to the Bombay presidency - - -	600,000	8,000,000
Total under the British government - - -	553,000	83,000,000
BRITISH ALLIES AND TRIBUTARIES.		
The Nizam - - - - -	96,000	10,000,000
The Nagpoor Raja - - - - - -	75,000	3,000,000
The King of Oude - - - - -	20,000	3,000,000
The Guicowar - - - - -	18,000	2,000,000
Kotah, 6,500; Boondee, 2,500; Bopaul, 5,000 - - -	14,900	1,500,000
The Mysore Raja - - - - -	27,000	3,000,000
The Satara Raja - - - - -	14,000	1,500,000
Travancore, 6,000; Cochin, 2,000 - - - - -	8,000	1,000,000
Under the Rajas of Jondpour, Jeypoor, Odeypoor, Bicancere, Jesselmere, and other rajpoot chiefs, Holcar, Ameer Khan, the Row of Kutch, Bhurtpoor, Macherry, and numerous other petty chiefs, Seikes, Gonds, Bheels, Coolies, and Catties, all comprehended within the line of British protection - - - - -	283,000	15,000,000
Total under the British government and its allies - -	1,103,000	123,000,000
INDEPENDENT STATES.		
The Nepaul Raja - - - - -	53,000	2,000,000
The Lahore Raja (Runjeet Singh) - - - -	50,000	3,000,000
The Ameers of Sinde - - - -	24,000	1,000,000
The dominions of Sindia - - - -	40,000	4,000,000
The Cabul sovereign, east of the Indus - - -	10,000	1,000,000
Grand total of Hindostan - - -	1,280,000	134,000,000
INDIA BEYOND THE GANGES. — *British Acquisitions in* 1824 *and* 1825.		
Countries south of Rangoon, consisting of half the province of Martaban, and the provinces of Tavoy, Ye, Tenasserin, and the Mergui isles - - -	12,000	51,000
The province of Arracan - - - - -	11,000	100,000
Countries from which the Burmese have been expelled, consisting of Assam and the adjacent petty states, occupying a space of about - - -	54,000	150,000
Total - - - - -	77,000	301,000

EASY. The sea phrase for a ship that moves over the sea without jerking or straining.

EAU DE COLOGNE. A perfumed spirit originally prepared at Cologne, and principally used as a perfume; though many imaginary medical virtues have also been ascribed to it. Various recipes have been published for the preparation of eau de Cologne, some of them extremely complicated. (See *Ure's Dictionary of Arts and Manufactures*, art. "Eau de Cologne.") The following affords a good imitation of the original article:—Take of alcohol one pint; of the oils of bergamot, orange-peel, and rosemary, each one drachm; of bruised cardamom seeds one drachm; orange-flower water one pint; distil one pint from a water-bath.

EAU DE LUCE. A strong solution of ammonia, scented and rendered milky by the addition of a little mastic and oil of amber. It is considered an effective remedy in India against the bites of poisonous snakes.

EAVES. (Fr. eaux.) In Architecture, the lowest edges of the inclined sides of a roof which project beyond the face of the wall so as to throw the water off therefrom, that being their office.

EBBING OF THE TIDE. The reflux of the tide. *See* TIDE.

EBENA'CEÆ. (Ebenus, one of the genera.) A natural order of shrubby or arborescent Exogens chiefly inhabiting the tropics. They are allied to *Oleaceæ*, with which they agree in the placentation of their seeds; but are distinguished by their alternate leaves, and axillary usually unisexual flowers. They are more closely related to *Aquifoliaceæ;* but differ in the number of their stamens and in their divided sexes. Some species are remarkable for the hardness and blackness of their wood, known under the name of ebony and iron wood; others, as the *Kaki* of China, yield an eatable fruit; all are beautiful objects when growing.

E'BIONITES. An ancient sect (referred by Mosheim to the second century), who believed in Christ as an inspired messenger of God, but considered him to be at the same time a mere man, born of Joseph and Mary. They maintained also the universal obligation of the Mosaic law, and rejected the authority of St. Paul. The origin of their name is uncertain, some deriving it from that of their supposed founder; others deduce it from a Hebrew word signifying *poor*, and suppose the title to be given to them in reference either to the *poverty* of the class to which they mostly belonged, or the *meanness* of their doctrine. (See *Gieseler's Eccl. Hist.* b. i. c. 3.)

E'BONY. *See* EBENACEÆ.

EBULLI'TION. (Lat. ebullitio, *bubbling up.*) The motion produced in a liquid by its rapid conversion into vapour.

ECCHYMO'SIS. (Gr. εκχεω, *I pour out.*) The extravasation of blood into the cellular membrane which results from blows and bruises.

ECCLE'SIA. (Gr. εκκλησια.) In Ancient History,

the great assembly of the Athenian people, at which every free citizen might attend and vote. This assembly, though nominally possessed of the supreme authority of the state from the earliest times, yet having no fixed times of meeting, was but seldom convened at all; so that the archons, who were elected from the body of nobles or eupatridæ, had virtually the whole management of the state. But the regulations of Solon, which appointed it to meet regularly four times in every period of thirty-five days, besides extraordinary occasions on which it might be convened, called it into active energy. Solon, however, restricted the subjects discussed in the Ecclesia to such as had before passed through the senate of five hundred; but when the democratic spirit of after times prevailed, this rule was not at all strictly observed. The magistrates who had the management of these assemblies were the Prytanes (*see* PRYTANES), the Prohedri (*see* PROHEDRI), and Epistates (*see* EPISTATES). The first of these sometimes convened the people, and hung up in a conspicuous place a programme giving an account of the matters to be discussed. The *Prohedri* proposed to the people the subjects on which they were to decide, and counted the votes. The *Epistate*, who presided over the whole, gave the liberty of voting, which might not be done before his signal was given.

The forms of their proceedings were as follow: — First, an expiatory victim was sacrificed, and his blood carried and sprinkled round the bounds of the assembly. Then the public crier demanded silence, and invited all persons above fifty years of age to speak; after that, any one who pleased. After the subject was discussed, they proceeded to vote on the crier's demanding of them, "whether they would consent to the decree proposed to them?" The votes were commonly given by show of hands, but on some occasions by ballot. When the suffrages had been examined and their numbers declared, the *Prytanes* dissolved the assembly. In order to incite the people to attend the Ecclesia, a small pay of one or three oboli was given for early appearance; and a rope, rubbed with vermilion, was carried through the Agora, to mark such as lagged behind, who were accordingly fined.

ECCLE'SIA'STES. One of the canonical books of the Old Testament, so called from the Greek word signifying a preacher. Solomon is generally supposed to be the author of this book, though various opinions have been entertained on the subject; and indeed the whole question of its author, date, and design is involved in such difficulty, "that the labours of critics and commentators serve rather to perplex than to assist the inquirer." (*Holden on Eccles.*)

ECCLE'SIA'STIC. Something pertaining to or set apart for the church; in contradistinction to *civil* or *secular*, which regards the world. Ecclesiastics are persons whose functions consist in performing the service or in maintaining the discipline of the church. *See* CLERGY.

ECCLESIASTICAL COURTS. The ordinary Ecclesiastical Courts in England and Wales are, beginning with the lowest, —

1. The Peculiar Courts, which are very numerous; Royal, Archiepiscopal, Episcopal, Decanal, Sub-decanal, Prebendal, Rectorial, and Vicarial; with jurisdiction frequently extending only to a single parish, and sometimes limited only to a part of the matters usually subject to ecclesiastical cognizance.

2. The Archdeacon's Court, generally subordinate, with an appeal to that of the bishop.

3. The Courts of Commissaries, especially appointed by the bishop.

4. The Diocesan Court of every bishop within his respective diocese.

5. The Provincial or Archiepiscopal Courts.

These, in the province of Canterbury, which contains twenty-two dioceses, are —

(1.) The Court of Peculiars, which takes cognizance of matters arising in some particular deaneries.

(2.) The Prerogative Court. This court has authority in the matter of all wills or administrations of property left by persons having *bona notabilia*, that is, personal estate to a certain amount, within several dioceses of the province. It grants administration to the effects of all such persons dying intestate, and probate of wills.

(3.) The Court of Arches, or Supreme Provincial Court of Appeal. It also may take original cognizance of causes, by letters of request from the inferior courts; and it has a separate jurisdiction of its own in suits for legacies.

The province of York, including four dioceses besides that of Sodor and Man, has two courts; the Prerogative Court, and the Chancery or Court of Appeal.

A suit is commenced in the Ecclesiastical Courts by a process, sued out by the party complaining, and served on the other party by an officer of the court. The party cited may appear either in person or by his proctor, who discharges duties similar to those of the attorneys in common law courts. A party disobeying citation may be pronounced contumacious, and imprisoned by an attachment out of the lord chancellor's court.

In case the party cited appear to show cause against his citation that the court has no jurisdiction, or that he is not amenable to it, this preliminary objection is heard upon petition and affidavits. If the judge decide against the defendant on the question of jurisdiction, the latter may apply to the courts of common law for a prohibition.

If the cause proceed to trial, the plaintiff's first statement of facts is termed, in criminal cases, *articles*; in testamentary causes, an *allegation*; in other civil proceedings, a *libel*. Every subsequent plea in all cases is called an allegation; and every allegation is divided into separate heads or articles; so that witnesses are produced and examined, not as to the whole allegation, but as to such special facts as may be within their knowledge. Where a plea has been admitted, a certain time, or *term probatory*, is allowed to the party making it to examine his witnesses.

The witnesses are either brought to London, or examined in the country by a commission. The depositions are taken in private, and in writing, by the examiners of the court; who, on view of the allegations, examine the witnesses by such questions as they judge most proper to elicit the truth. The cross-examination is conducted by means of interrogatories, delivered by the adverse party to the examiner, and by him addressed to the witness. The examinations are kept secret until publication passes; after which either party is allowed to except, by a plea called an exceptive allegation, to the credit of an adverse witness.

When the cause is heard, the judge first peruses and carefully considers all the pleas and evidence, and then hears the case argued by counsel. Judgment is given in open court; and execution enforced by the compulsory process of *contumacy*, *significavit*, and *attachment*. Such is a very general view of the ordinary process of these courts.

If either party be condemned in costs, the other party's bill is taxed by the registrar. But the costs due by a party to his own proctor cannot be recovered in this court, and must be sued for by an action at law.

The law of the Ecclesiastical Courts is administered by men associated, as a distinct profession, for the practice of the civil and canon laws. They are incorporated as "the college of doctors of law." Every advocate must have taken that degree in the university of Oxford or Cambridge. From the college of advocates the archbishop selects the judges of the provincial courts.

The jurisdiction of these courts may be considered as threefold: — 1. In causes of a purely spiritual nature pertaining to the discipline of the church; 2. In mixed causes, partaking of a spiritual and civil nature; 3. In causes of a purely civil nature.

1. The first of these branches arises out of the natural power exercised by every church to correct its communicants by censures and discipline submitted to. Under this class falls the cognizance of offences committed by the clergy themselves by neglect of duty, immoral or heretical delinquencies, suffering dilapidations, &c.; also by laymen, in brawling and other indecent conduct in churches and churchyards, in neglecting to repair churches, in cases of incest, incontinence, defamation. All these, except the last, are termed "causes of correction." The punishments inflicted are monition, penance, excommunication, suspension *ab ingressu ecclesiæ*, and (in the case of clergymen) suspension from office and deprivation. In the case of laymen a great part of this jurisdiction has fallen into disuse; and the real penalty, whenever a cause is tried, consists, for the most part, in the payment of costs by the guilty party. The terrors so long attached to the process of excommunication (the only one by which ecclesiastical courts can enforce a sentence), are now matter of history. By the common law a person excommunicated was incapacitated from any legal act, and was, moreover, on certificate from the bishop, liable to imprisonment until reconciled to the church; but now, by the statute 53 George 3. chapter 127., the writ de contumace capiendo is substituted for the old writ de excommunicato capiendo in cases of contempt; and in the few cases in which excommunication is still pronounced as a sentence the court is empowered to assign a term of imprisonment, not exceeding six months. 2. Causes of a mixed description are suits for tithes, church rates, seats in churches, and faculties; which concern the temporals or external possessions of the church. The subtraction of tithes or other ecclesiastical dues may be complained of in the Ecclesiastical Courts; but if any question of law arises on the defence, as where modus or prescription is relied on against a claim of tithe, either party may apply for a *prohibition* from the King's Bench, as the Ecclesiastical Court has not authority to decide the point of law. Suits of this description are consequently of rare occurrence. The Ecclesiastical Court exercises jurisdiction to enforce the payment of church rates; but where the amount to be recovered does not exceed 10*l.*, and the validity of the rate is undisputed, two justices may enforce payment by distress. 3. Exclusive property in a seat in the body of the

church can be claimed only in virtue of a faculty, that is, a grant from the ordinary (or immediate ecclesiastical superintendent); or of a prescription, that is, immemorial usage, presumed to be founded on a faculty. But the courts of common law interfere, — 1. Where the pew is claimed as annexed to a house; 2. In all cases of prescription, in which a prohibition will be granted to remove the cause from the ecclesiastical tribunal in order to have the prescription tried by a jury. Causes of a purely civil nature, although in their origin supposed to possess something of a spiritual character, are testamentary and matrimonial. And these constitute the bulk of the business transacted in our Ecclesiastical Courts. The jurisdiction of these courts over wills is of very ancient date in England; while it either ceased at an early period or was never held valid in other Christian countries. The distribution of the personal effects of persons who died intestate was entirely at the discretion of the ordinary. This is one of the rights confirmed to the prelates by Magna Charta. The absolute power of the ordinary was first limited by Edward I., in whose reign he was compelled to discharge the intestate's debts; and in the reign of Edward III. he was obliged to divide them, by means of administrators, among the kindred of the deceased, in proportions which were finally determined by the Statute of Distributions. *See* Administration.

As a natural consequence of their power to distribute intestates' effects, the bishops acquired a jurisdiction over wills, both to determine their validity, and to decide disputes respecting bequests of personal property; hence arose the *granting probate of wills*, and suits for legacies. (*See* Will.) The courts of common law exercise exclusive jurisdiction over all testamentary devises of real estate; the ecclesiastical courts possess a similar power over bequests of personal estate; but courts of equity have no authority to determine the validity of a will of any description of property. Hence, in a devise of land, a judge and jury determine on vivâ voce evidence; in a bequest of personalty, the judge of the ecclesiastical court on depositions reduced into writing; and when the will relates both to real and personal estate, there may be a double trial and conflicting determinations.

Matrimonial causes form the next and most important branch of ecclesiastical jurisdiction. (*See* Marriage, Law of.) Directly, the ecclesiastical courts have the sole cognizance of the validity of a marriage; but indirectly, the common law courts assume this jurisdiction whenever the question arises in a civil or criminal proceeding before them.

ECCLE'SIA'STICUS. An apocryphal book, composed, as is generally supposed, by Jesus the son of Sirach, and admitted by the Romish church into the canon of the Old Testament. This book was originally written in Syro-Chaldaic, and consists chiefly of meditations relating to religion and the general conduct of human life. It displays but little regard for methodical arrangement; but the style is so highly poetical, and the sentiments so profound, that Addison (*Spectator*, No. 60.) has pronounced it one of the most brilliant moral treatises on record.

ECCOPRO'TICS. (Gr. ἐκ, *out*, and κοπρος, *excrement*.) The term formerly applied to mild aperient medicines.

E'CHEA. (Gr. ἠχεω, *I sound*.) In Ancient Architecture, sonorous vases of metal or earth in the form of a bell, used in the construction of theatres for the purpose of reverberating the sound of the performer's voice. They were distributed between the seats; and are described in the fifth book of Vitruvius, who states that Mummius introduced them in Rome, after the taking of Corinth, where he found this expedient used in the theatre.

E'CHELON (Fr.), in the art Military, signifies the position of an army, when its divisions are so formed as to be behind one another in the form of steps.

ECHI'DNA. In Grecian Mythology, the daughter of Geryon and the sea-nymph Callirhoe, or of Tartarus and Gaia; a monster that devoured travellers: parent, according to Hesiod, of those well-known terrors of ancient Greece, — Cerberus, the Hydra, the Sphinx, and the Nemean lion. Hence some suppose the name to represent a sort of general type of monsters and terrific phenomena.

Echi'dna. In Zoology, a name proposed by Cuvier for a genus of Australian quadrupeds, having the general form of an ant-eater, but covered with spines. The *Echidna*, like the *Ornithoryhnchus*, deviates in a remarkable manner from the typical structure of the mammalia in general in the organization of the generative and osseous systems, and forms with it a family or order called *Monotrema*. (See that word.) In the male of the *Echidna*, as in the *Ornithorhynchus*, the hind foot is armed with a curved spur, perforated like the fang of a viper by the duct of a poison gland, whence probably the reason for the name. Among the colonists of Australia, the *Echidna* is generally known by the name of the porcupine. It frequents sandy localities, lives in burrows, and feeds on ants and other insects, which it entraps by means of a long and adhesive tongue.

ECHINA'TUS, in Botany, signifies bristly.

ECHI'NOCO'CCUS. (Gr. ἐχινος, *a spine*, and κοκκος, *a cyst*.) A genus of Hydatids or Cystic Entozoons, of which one species (*Echin. hommis*) is recorded by Rudolphi as infesting occasionally the human subject.

ECHI'NODERMS, *Echinoderma*. (Gr. ἐχινος, *a hedgehog*, and δερμα, *skin*.) A name applied to a class of Invertebrate animals, which have a crustaceous or coriaceous integument, most commonly armed with tubercles or spines.

ECHINO'PORA. (Gr. ἐχινος, *a spine*, and πορος, *a pore*.) A subgenus of *Madrepores*. See that word.

ECHI'NUS. (Gr. ἐχινος.) The generic name of the sea-urchins, which constitute the type of the class *Echinoderma*. The Linnæan genus is now subdivided into many subgenera; some of which have their names compounded of Echinus and some other word, as *Echinobrissus, Echinocidaris, Echinoclypeus, Echinoconus, Echinocorys, Echinocyamus, Echinodiscus, Echinoampas, Echinometra, Echinoneus, Echinorodon*, &c.

Echinus. In Architecture, the same as the ovolo or quarter round, though the moulding is only properly so called when carved with eggs and anchors. (*See* Anchors.) It is the shell or husk of the chesnut, though the ornament does not seem to bear much resemblance to it.

E'CHO. (Gr. ἠχω, *sound*.) A sound reflected from a distant surface, and repeated to the ear. When sound in its passage through the atmosphere meets an obstacle, the molecules of air in vibration are reflected in the same manner as elastic bodies, and communicate to the contiguous molecules a vibratory motion, which is propagated in the direction determined by the inclination of the opposing surface to the original direction in which the sound reaches it, the angle of incidence being equal to the angle of reflection. Though echo is a simple consequence of the reflection of sound, several conditions must be fulfilled before it can be produced. In the first place, it is necessary that the ear be situated in the line of the reflection; and in order that the person who emits the sound may himself hear the echo, this line must be perpendicular to the reflecting surface, at least if there is only one reflecting surface; but if there are several such surfaces properly disposed, the sound may be brought back by a series of successive reflections to the point from which it emanated. In the second place, it is necessary that the opposing surface be at a certain distance from the ear; for if the direct and reflected sound succeed each other with great rapidity, they are in some measure confounded, and the echo cannot be distinguished. Hence large rooms and vaulted caves have a strong *resonance*, but no echo is produced by them; the proximity of the walls rendering it impossible to distinguish the reflected sounds.

Observation proves that sound passes through the atmosphere at the rate of about 1125 feet in a second; hence a person placed at half that distance, or 512 feet from the reflecting surface, would hear the echo exactly one second after the sound was emitted by him, and the echo would repeat as many distinct sounds as the ear can distinguish in a second. The utmost number of sounds which any ear can distinguish in a second perhaps does not exceed ten; hence the least distance of the reflecting surface from the point whence the sound is emitted must be about 50 feet, in order that an echo may be produced.

Every thing which is capable of reflecting sonorous pulses may cause an echo; whence the wall of a house, or the rampart of a city, a wood, rocks, or mountains, produce echos. Unless, however, the surface which reflects the sound is of considerable extent, the echo will be too feeble to be heard. A certain degree of concavity in the surface, by which several diverging rays of sound are collected and concentrated at the point where the echo is audible, if not absolutely essential, is at least highly favourable to the production of echos. It is a property of the ellipse that every sound proceeding from one of its foci, and impinging against the curve, is reflected into the other focus; whence two persons placed in the two foci of an elliptic chamber may converse with each other in a whisper, and their voices not be heard by those who are in the other parts of the room. Hence also walls or buildings approaching to the elliptic form return sounds with great distinctness and force. In the whispering gallery of St. Paul's, the faintest sound is conveyed from one side of the dome to the other, but is not heard at any intermediate point. In Gloucester cathedral a gallery of an octagonal form conveys a whisper 75 feet across the nave. Some echos are remarkable for their frequency of repetition. An echo in Woodstock Park repeats 17 syllables by day and 20 by night. Southwell (*Phil. Trans.* 1766) describes an echo in the Simonetta palace, near Milan, which repeated the report of a pistol 60 times. In *Birch's History of the Royal Society*, an account is given of an echo at Rosneath, near Glasgow, that repeats a tune played with a trumpet three times, completely and distinctly.

Echo, in Architecture, is a term often applied, though improperly, to certain vaults and arches, usually of an elliptic or parabolic form, made for the purpose of producing artificial echoes.

ECHO'METER. In Music, a sort of scale or rule, marked with lines, which serve to measure the duration of sounds, and to ascertain their intervals and ratios.

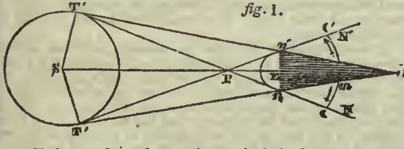
ECLE'CTICS. (Gr. ἐκλέγω, *I pick out.*) Those philosophers who endeavour to select from the systems of various schools those doctrines alone which are true, and to present these in the form of an entire whole. An eclectic spirit, it is evident, can only arise at a period of some maturity in philosophical speculation. Whether or not it is to be regarded as an evidence of the decay of original power in the age in which it appears, must depend on the less or greater coherence in the system when completed. In one sense of the word, Plato and Aristotle may be regarded as eclectics. They both availed themselves largely of the labours of their predecessors. Plato, in particular, comprehended in his scheme of philosophy the whole of more than one foregoing system; as the doctrine of Heraclitus of the perpetual flux of sensible objects, and the consequent uncertainty of sensible impressions. But in the hands of these great thinkers the *discerpta membra* are reunited, and endued with a principle of vitality as constituent parts of a harmonious whole. The same cannot be said of others who have adopted a similar method; especially of most of those to whom the term *eclectic* has been more peculiarly applied. These philosophers lived chiefly under the Roman empire. The most celebrated among them may be said to have been Epictetus (A. D. 90) and Plutarch. The latter, in particular, a man of great and various endowments, may yet be taken as a striking instance of a false eclecticism. His great object, in his philosophical writings, seems to have been to reconcile the profound speculations and pure morality of the philosophers with the fanciful inventions and the gross theology of the poets and priests of Greece, Italy, or Egypt.

A far more favourable specimen of the eclectic spirit has been afforded us in modern times in the person of M. Victor Cousin, without doubt the most able and ingenious thinker of modern France. See his *Lectures on the Hist. of Philosophy*, in which eclecticism is presented under its fairest guise, and vindicated with the utmost vigour of style and acuteness of thought.

ECLI'PSES (Gr. ἔκλειψις, from ἐκλείπω, *I faint away or disappear*), taken in a general sense, are those phenomena which exhibit the obscuration of astronomical luminaries, and may be divided into two kinds, in reference to the circumstances under which they are presented; viz. 1. When the obscuration is caused by an interception of the light received by the luminary from the sun; as in the cases of eclipses of the moon, eclipses of Jupiter's satellites, &c. 2. When the obscuration is caused by an interception, either totally or partially, of the light transmitted from the luminary to the spectator; and this kind consists of eclipses of the sun, occultations of stars and planets by the moon, and the transits of Mercury and Venus over the disc of the sun.

The most popular and generally interesting objects are the eclipses of the sun and moon; and their causes and aspects will here deserve some explanation. The earth and moon being opaque bodies are illuminated by the sun; and, just as we observe with small opaque bodies on the surface of the earth which are within the range of ocular examination, they cast their shadows in directions which are opposite to the sun. As the figures of the bodies are nearly spherical, and as the sun is the largest, it is plain that these shadows must be very nearly of a conical form. The moon is eclipsed when it becomes involved in the shadow of the earth, and so deprived of the light it is accustomed to receive from the sun; and this can take place only at the time of full moon, or when the moon is in opposition to the sun. Let S represent the

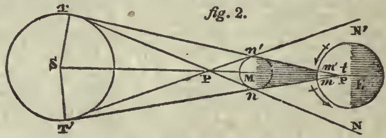
fig. 1.



sun, E the earth, and $n' t n$ its conical shadow, into which the rays of the sun do not enter. This shadow must evidently be a portion of the larger cone T t T′ which envelops both bodies. Suppose the plane of the paper to be the plane of the ecliptic, or the plane in which the earth moves round the sun, and let ☾ ☾′ represent a portion of the path of the moon round the earth, the arrows indicating the direction of her motion. Conceive also by means of cross tangents T P ☾, T′ P ☾′ the two opposite and circumscribing cones T P T′, ☾′ P ☾ to be drawn. The latter of these cones, ☾′ P ☾, is called the *penumbral cone;* and the space N n n' N′, projected beyond the earth, is called the *earth's penumbra*. It is evident that any position within this penumbra is at least partially deprived of the light of the sun; for if we imagine a spectator to be in that position, it is obvious that the interposition of the earth would act as a partial screen and obscure a portion of the sun's disc from his view. It is also evident that a greater portion of the disc of the sun would be hidden from this supposed spectator as his position approaches nearer to the earth's shadow; and that if we suppose him to enter the shadow, he will become totally deprived of the light of the sun, the disc of the sun in this case being entirely hidden by the intervention of the earth. From this observation it follows that as the moon advances in the penumbra from ☾ to m her disc will receive less and less light from the sun, and its brightness will gradually diminish; also, as soon as a portion of the moon's disc enters the shadow, that portion becomes totally deprived of the light of the sun, and is, in other terms, darkened or eclipsed. If in the course of the eclipse only a part of the moon's disc enters the earth's shadow, it is called a *partial eclipse;* but if the moon is totally darkened by the whole disc entering the shadow, it is called a *total eclipse*. It is to be understood in the diagram that the orbit of the moon, or the path she describes round the earth, is not in the plane of the ecliptic or the plane of the paper, but inclined to it at an angle always greater than 4° 57′ and less than 5° 21′. This is the reason why eclipses of the moon do not happen at every full moon, for they can only take place when the moon's elevation above the ecliptic at full moon happens to be less than the semidiameter of the section of the earth's shadow through which she passes. In the course of a year there may be three eclipses of the moon, which is the greatest number that can happen; but there must always necessarily be two.

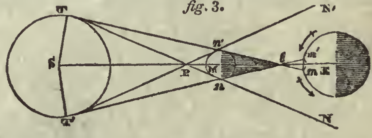
At the time of new moon, or when the moon is between the sun and the earth, her shadow or penumbra may fall on the disc of the earth at certain places, and prevent either all or part of the light of the sun from reaching those places on the earth's surface. This circumstance produces the phenomenon of a total or partial eclipse of the sun, which is limited to the portion of the earth on which the moon's shadow or penumbra happens to fall. The shadow of the moon does not always reach so far as the earth. In the two following diagrams, annexed by way of illustration, the former represents the case in which it does reach, and the latter represents the case in which it

fig. 2.



does not reach, the surface of the earth. The shadow of the moon in the first diagram falls upon a portion of the earth's surface between m and m'; and the inhabitants, if any, of that portion, will evidently, from what has been said before, have the sun's disc wholly covered by the intervention of the dark body of the moon, and therefore

fig. 3.



have presented to them a *total eclipse of the sun*. But in the second diagram, where the shadow of the moon does not reach the earth, if we suppose the dark conical shadow $n t n'$ to be produced into the small opposite cone $m t m'$ meeting the surface of the earth, it will be obvious, after a slight consideration, that any supposed spectator within this latter cone, or any inhabitant of the portion $m m'$ of the earth, will perceive the dark body of the moon wholly within the disc of the sun, and intercepting only an interior part of his light; the unobscured part of the sun which circumscribes the disc of the moon will consequently present the appearance of a beautiful luminous ring or annulus, and the eclipse exhibiting this aspect is commonly called an *annular eclipse* of the sun; the cone $m t m'$ may be similarly called the *annular cone*. It does not always occur, during the progress of an eclipse of the sun, that either the dark shadow of the moon or the annular cone will fall on the earth's surface, and it very rarely happens that either of them will fall on any defined spot, such as London or Edinburgh. For the occurrence of an eclipse on the earth, it is only necessary that the moon's penumbra N n n' N′ shall be projected against a portion of the terrestrial surface, as an inhabitant of that portion will at least have a part of the disc of the sun intercepted by the moon. When neither the moon's shadow nor the annular cone meets the earth in the course of an

eclipse, and consequently only a part of the sun's disc is obscured to terrestrial vision, it is called a *partial eclipse of the sun*, and in that respect it is similar to a partial eclipse of the moon. If in the two diagrams we suppose, as before, the plane of the paper to be the plane of the ecliptic, the position of the moon must not necessarily be considered to be in that plane. The north pole of the earth will be directed upwards at an angle of about 23° 28′, and the arrows will represent the direction in which the earth revolves about its axis; the moon proceeds round the earth in the same direction, and carries her penumbra across the earth's surface with a much greater velocity than the earth's rotation. It follows, therefore, that the arrows indicate also the direction in which the phenomena of the eclipse pass geographically over the earth, viz. from west to east; and that different places will have the eclipse at a later or earlier time, according as they are more to the east or west. Eclipses of the sun occur more frequently than eclipses of the moon. In the course of each year there must be two at least in some parts of the earth; but there cannot possibly be more than four,—a number that sometimes, though very seldom, happens.

Calculation of Eclipses of the Sun and Moon.—It is here chiefly intended to explain methods by which the times of beginning and ending of any phase or appearance may be predicted for a particular place on the earth. For these calculations it is necessary, first, to ascertain the longitudes and latitudes of the sun and moon by means of the solar and lunar tables. Those of the sun may be determined from the revised tables of Carlini, which form the supplement to the *Milan Ephemeris* for the year 1833; and those of the moon may be calculated from the tables of Burckhardt or Damoiseau. With the help of the tables, the hourly variations of the same quantities, as well as the horizontal parallaxes and semidiameters of both bodies, are to be calculated. The results so found will be elements from which the phenomena of the eclipse may be determined for any stated place on the earth; but their computation is necessary only for eclipses that occur at remote periods, since all these calculations are accurately executed and registered in the *Nautical Almanac*, a work regularly published three or four years in advance. The positions are there likewise reduced to the plane of the equator, so as to determine the places of the bodies by their right ascensions and declinations, which are more readily applicable to the calculation of *all* the circumstances of an eclipse; besides, the right ascensions and declinations of the moon are given with the utmost precision for every hour, which adds considerably to the facility of these calculations. It will here be the more generally useful and interesting, therefore, to describe methods by which, with the use of the *Nautical Almanac*, the circumstances of an eclipse may be predicted, as it will appear from any given spot on the earth's surface.

In the diagram (*fig.* 1.) join E m, E ☾, S n, and denote

E mn = the moon's horizontal parallax, by P,
E S n = sun's —— by π,
T n S = sun's semidiameter, by σ;

then the angle M E m is the semidiameter of the section of the earth's shadow traversed by the moon, as it would be seen from the centre E; and the angle M E ☾ is the similar semidiameter of the penumbra. To determine the semidiameter of the section of the shadow, we have mEt = Emn − Etm = Emn − (SnT − nSt) = Emn + nSt − SnT; that is, the semidiameter of the shadow = P + π − σ. This value, however, is affected by the atmosphere of the earth, which absorbs those rays of the sun that would pass near to the surface, and thus makes the shadow of the earth to appear sensibly larger. To take this effect into account, it is the usual practice of astronomers to increase the value given by the preceding expression by one-sixtieth, or to add as many seconds as there are minutes in the radius of the section. The actual formula employed in this calculation is therefore

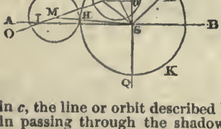
$$\text{Semid. of shadow} = \frac{61}{60}(P + \pi - \sigma).$$

By adding to this the angle m E ☾ = mn ☾ = T n T′ = 2σ, we have also,

$$\text{Semid. of penumbra} = \frac{61}{60}(P + \pi - \sigma) + 2\sigma.$$

Let the circle H H′ K represent the section of the earth's shadow through which the moon passes during the eclipse; P Q a portion of the circle of declination which passes through the centre S and the north and south poles, P being towards the north, and S towards the south; A B a portion of the parallel of declination, which also passes through S; O R, intersecting P Q in c, the line or orbit described by the centre of the moon in passing through the shadow; M her position when

Fig. 4.



she first comes into contact with the shadow, and begins to be eclipsed at H; m her position at the middle of the eclipse, or time of greatest obscuration; and M′ her position at leaving the shadow when the eclipse ceases. In the figure, for the sake of convenience, the shadow is supposed to be fixed; and hence the motion of M is not considered to be the entire motion of the moon, but the motion with which she passes through the shadow, or, as it is called, the relative motion of the moon. This relative motion is equal to the difference between the motion of the moon and that of the shadow. But as the centres of the sun and shadow must always be in opposite points of the sphere, as seen from the centre of the earth, the motion of the shadow will be just the same as that of the sun.

At any assumed time T, near to the time of opposition, let a be the position of M, and draw ab parallel to A B; at this instant let α denote the difference between the right ascensions of the moon and shadow; also let x = Sb, and y = ab. Then, from what has preceded,

Right ascension shadow = right ascension ☉ ± 12ʰ.

Declination shadow = declination ☉ with a contrary name.

α = right ascension shadow − right ascension ☾
x = declination ☾ − declination shadow
= declination ☾ + declination ☉.

But as $ab = y$ may be considered to be part of a parallel of declination, and as α is the spherical angle it subtends from the pole, it is evident that $y = \alpha \times$ cos. ☾'s declination. We must therefore first calculate the following quantities:—

Right ascen. shadow = right ascen. ☉ ± 12ʰ.
y = (right ascen. shad. − that of ☾) × cos. ☾'s dec.
hourly mo. y = (hor. mo. ☾'s right ascen. − that of ☉) × cos. ☾'s dec.
x = ☾'s dec. + ☉'s dec.
hourly mo. x = hor. mo. ☾'s dec. + hor. mo. ☉'s dec.

It will be here observed that hourly mo. y denotes the decrease of y, while hourly mo. x denotes the increase of x, in one hour.

If i denote the angle c I S or m S c, which is the inclination of the relative orbit O R with the parallel A B, we find also,

$$\tan. i = \frac{\text{hourly mo. } x}{\text{hourly mo. } y}$$

$$\text{hourly motion in the orbit } o\text{R} = \frac{\text{hourly mo. } y}{\cos. i}.$$

Again, in the right-angled triangle abS, knowing the sides Sb = x, and ab = y, we calculate the angle aSb and the distance Sa. The difference of the angles aSb, mSc, gives the angle aSm; and in the right-angled triangle aSm, knowing also the side aS, we find the other two sides am, Sm, the latter of which is the nearest distance of the centres of the moon and shadow. The distance S M, at the beginning or ending of the eclipse, is found by adding the semidiameter of the moon to that of the shadow; hence, in the triangle M S m, knowing also the side Sm, we find the side Mm = mM′; and by subtracting and adding the value of am, before found, we get the distances Ma, aM′. Knowing therefore these distances, and the hourly motion in the orbit O R, we find the times employed by the moon in traversing them: the former of these times, subtracted from the time originally assumed at which the elements were taken, will therefore give the time of the beginning of the eclipse; and, similarly, by adding the latter, we get the time at which the eclipse will terminate. The times thus found will be for the meridian of Greenwich, and will require reducing for the longitude of the place.

To those who are not familiar with algebraical operations, a rough sketch of the figure, drawn by the hand, will indicate most distinctly the way in which the several angles and lines ought to be combined in the process of the calculation.

For an eclipse of the sun the relative positions of the sun and moon are not independent of the observer's position, like those of the moon and the earth's shadow. In the calculation of an eclipse of the sun, we must first apply the effects of the relative parallax to the right ascension and declination of the moon to get her exact position with respect to the sun, as she will appear to a spectator at the place for which the calculation is proposed to be made. (See the article PARALLAX.) By subtracting and adding the hourly motions, given in the *Nautical Almanac*, we obtain the values of the quantities for an hour before and after the time of conjunction in right ascension. Then, after calculating and applying the effects of parallax to the moon, we find the quantities x, y, in the same manner as for an eclipse of the moon, only substituting the sun in place of the sections of the earth's shadow. The half differences of the quantities so computed for an interval of two hours will show their apparent hourly motions; and with these the remaining calculation, for either time, is precisely the same as has already been described for an eclipse of the moon. It is only further to be observed, that as the apparent relative motion of the moon is not

very uniform, the results will be most accurate when they are close to the times assumed. If a very accurate calculation of the beginning or ending be required, it will, for this reason, be necessary to repeat the calculation for a single assumed time close to the occurrence of the phase; and for this purpose we may adopt the hourly motions in the first calculation. In these cases, greater accuracy is to be obtained by interpolating the right ascensions and declinations from the running ephemeris than by inferring them from the list of elements.

ECLI'PTIC. In Astronomy, the great circle of the heavens which the sun appears to describe in his annual revolution. It has been called the *ecliptic*, because eclipses only happen when the moon is in the same plane, or very near it. The ecliptic, from time immemorial, has been conceived to be divided into twelve equal parts, called *signs*, — Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, Pisces. But the signs of the ecliptic are not to be confounded with the *signs of the zodiac*, which denote the places occupied by certain constellations, and consequently never alter their position in the heavens. The signs of the ecliptic denote merely arcs of 30°; and as they are reckoned from the intersection of the equator and ecliptic, which is not a fixed point, their limits are not, in all ages, determined by the same stars.

The ecliptic is the circle to which longitudes and latitudes in the heavens are referred, as right ascensions and declinations are referred to the earth's equator.

The angle which the plane of the ecliptic makes with the plane of the equator is called the *obliquity of the ecliptic*. It is to the oblique position of these two planes that we owe the vicissitudes of the seasons. If the equator coincided with the ecliptic, the days and nights would always be equal at all parts of the earth, and there would be no summer or winter.

The obliquity of the ecliptic at the present time (Jan. 1. 1840) is 23° 27′ 36·52″. (*Nautical Almanac.*) This quantity, besides being subject to a periodic variation of about 18″, arising from the nutation of the earth's axis, is affected by a *secular* inequality, of which the period is not ascertained. By comparing the observations of the present times with those made in former ages, it is found that the obliquity has continued to undergo a slow progressive diminution, the rate of which appears to be about 45″ in a century, amounting to a fourth of a degree since the time of Hipparchus. The planes of the ecliptic and equator have consequently been approaching each other during the last 2000 years; but though mathematicians have not yet ventured to assign the limit of this approach, it cannot exceed a certain small quantity; and, after a few thousand years more, the two planes will begin again to recede. The diminution of the obliquity is caused by the action of the other planets, particularly Venus and Jupiter, on the earth; in virtue of which action the plane of the earth's orbit is drawn, as it were, nearer to the planes of these two planets. *See* NUTATION, and PRECESSION OF THE EQUINOXES.

ECLIPTIC DIGITS. *See* DIGITS.

ECLIPTIC LIMITS, are the greatest distances at which the moon can be from her nodes, in order that an eclipse of the sun or moon may happen. When the moon is within those limits at the time of the new or full moon, an eclipse certainly happens; but when the moon is beyond those limits, an eclipse cannot happen. The limits for an eclipse of the sun are about 17°, and for an eclipse of the moon about 12°.

E'CLOGUE. (Gr. ἐκλόγη, *a selection.*) In the original meaning of the word, the select or choice pieces of an author; or extracts collected out of former works, such as were termed in Latin *excerpta*. It is not known how this title was originally given to the pastoral poems of Virgil; but from the circumstance of their being so named, the word eclogue in modern usage is applied to that species of poetry. The persons who are introduced conversing in eclogues, or whose adventures are recounted in them, are shepherds; that is, for the most part, imaginary personages, whose sentiments, and the external circumstances among which they live, belong rather to an ideal age of gold than to the realities of modern life; and their loves constitute the main and proper subjects of the eclogue. Nevertheless various writers (Gay, &c. among ourselves) have endeavoured, but with little success, to give an air of greater reality to pastoral poetry, and give their rustics more of the costume and diction of actual clowns; but the result has been a species of burlesque, not at all answering to our conceptions of pastoral poetry; nor can we easily imagine that the personages of Theocritus, although the earliest and therefore the simplest of pastoral poets, are correct resemblances of the Sicilian rustics among whom the writer lived. The eclogues of Virgil are of various descriptions: some of them only have the true character of pastorals; others contain occasional poems on public and private events of the day, very slightly enveloped in the pastoral costume. The characteristics of this species of poetry, as assumed by the moderns, are, first, the representation of nature in soft and quiet scenes of cultivation; secondly, a slightly dramatic turn either of action or narration; thirdly, characters whose sentiments and language are confined within certain peculiar limits: thus, any strong emotion, virtue, or vice, would be an unfit topic for a pastoral poet to dwell upon. Among ourselves, Spenser, Philips, and a few others, may be named as pastoral poets in the strict sense of the word; others, as Milton in his *Lycidas*, have assumed the pastoral costume in order to convey a very different class of ideas. It is worthy of remark, that this species of composition is among those which have wholly disappeared in the present day: we have had no pastoral poet since Gay and Collins; and Gesner, in Germany, is the latest author who has acquired any degree of celebrity in this line. *See* IDYLL, BUCOLIC.

ECO'NOMY, POLI'TICAL. *See* POLITICAL ECONOMY.

ECTHY'MA. (Gr. εκθυω, *I break out.*) An eruption of pimples or small pustules common in young persons after having overheated themselves, or eaten indigestible and greasy things. Analogous eruptions are seen upon infants, especially those who are ill-nursed. Proper diet, mild aperients, especially small doses of rhubarb and magnesia, generally carry them off.

ECTRO'PIUM. (Gr. εκτρεπω, *I evert.*) An unnatural eversion of the eyelids, arising from tumefaction of the inner membrane, or from a contraction of the skin covering the eyelid.

ECZE'MA. (Gr. εκζεω, *I boil out.*) An eruption of the skin frequently observed in irritable habits, and sometimes mistaken for the itch: it is not pustular, but consists of small vesicles, often forming patches or blotches, and producing, as they die off, a desquamation of the cuticle. Alteratives and cooling local applications are the remedies usually resorted to for the relief of this complaint.

E'DDA. The ancient collection of Scandinavian poetry in which the national mythology is contained. There are two Eddas: the older is believed to have been reduced to writing, from oral tradition, in Iceland, between A.D. 1050 and 1133. It was recovered and published in Denmark in 1643. The new Edda, supposed to have been composed 200 years after the former, is an abridgment of it, with a new arrangement of its parts. It was translated by Resenius in 1640, and is thence called the Resenian Edda. The authenticity of these monuments of an early age has been doubted in recent times, but the latest researches of critics (the brothers Grimm and others) seem to go far towards establishing it. (See the *Penny Cyclopædia.*)

E'DDY (Sax. ed, *water*, and ea, *backwards*), is the water of a stream or tide which, in consequence of striking against some obstacle, is thrown backwards, and runs in a direction opposite to that of the general current. More frequently, however, the term is used to denote the whirling or circular motion caused by the meeting of two opposite currents; and, in this sense, it is also applied to a similar motion of the atmosphere. *See* WHIRLPOOL, WHIRLWIND.

EDE'NTALS, *Edentata*. The name of an order of Mammals, including those genera in which the dental apparatus is more or less incomplete: the incisive teeth are almost always deficient.

E'DICT. (Lat. edico, *I speak out.*) An instrument signed and sealed by a despotic prince to serve as a law to his subjects. In ancient Rome, the ordinances of the magistrates, but especially of the two prætors, *prætor urbanus* and *prætor peregrinus*, were so called. Previously to the time of Augustus, the grand principles of Roman law were exceedingly ambiguous and undefined; and to remedy this defect in some measure, the prætors used to publish, on their accession to office, *edicts* or rules for regulating the practice of their courts, as well as for their own guidance in the decision of doubtful cases. A jurisdiction, however, thus vague and arbitrary in its nature being constantly abused, it was enacted by the Cornelian Law (B.C. 56), that the prætor of the year should be compelled to adhere to the spirit and letter of his first proclamation. The edicts of the preceding prætor were not binding on his successor. If the latter confirmed them, they were styled *edicta vetera* or *tralatitia;* in contradistinction to *edicta nova*, those framed by himself. (*See* PRÆTOR.) Under the emperor Hadrian, a digest of the best decisions of the prætors from the earliest times was made by Sylvius Julianus, collected into a volume called *Edictum Perpetuum*, or Perpetual Edict, ratified by the emperor and senate, and fixed as the invariable standard of civil jurisprudence.

The *Edict of Milan* was a proclamation issued by Constantine after the conquest of Italy (A.D. 313), to secure to the Christians the restitution of their civil and religious rights, of which they had long been deprived, and to establish throughout his extended dominions the principles of a wise and enlightened toleration.

The most famous edict of modern history is the Edict of Nantes, issued by Henry IV. in 1598, to secure to the Protestants the free exercise of their religion. This act, after continuing in force nearly a century, was repealed

by Louis XIV.; and, as is well known, its revocation led to a renewal of the persecutions and bloody scenes which previously to the issuing of this edict had been enacted against the Protestants. The depopulation caused by the sword was also increased by emigration. Above half a million of her most useful and industrious subjects deserted France, and exported, together with immense sums of money, those arts and manufactures which had chiefly tended to enrich the kingdom. About 50,000 refugees passed over into England; and there can be little doubt that their representations of the cruelties perpetrated by the King of France tended to excite the suspicions of the English against their own Roman Catholic sovereign, and in some degree accelerated the advent of the Revolution of 1588. *See* HUGUENOTS.

In the French law, the term *edict* has a wide signification, being applied equally to the most momentous and the most trifling proclamations of the government.

E'DINGTONITE. A mineral found near Dumbarton in small greyish-white translucent prisms, composed of silica, alumina, lime, water, and probably some alkali.

EDI'TION (from the Latin verb edere, *to give out or publish*), means simply the (indefinite) number of copies of a work printed at one time, before the types are distributed by the compositor. Any one who prepares for publication the writings of another is said to edit them, and is called the *editor*. In literary language, since the invention of printing, the *editor* of a work revises, adds notes, prepares for the press, &c. &c.: the *publisher* is the bookseller who negotiates the sale of the impression. Sometimes (but especially in classical works) the edition goes generally by the name of the printer or publisher, sometimes by that of the editor. Thus, we have the Aldine and Elzevir Classics, &c., the houses of Aldus and Elzevir having been concerned both in printing and publishing; while *Bentley's Horace*, *Heyne's Homer*, &c., are so denominated from the name of the *editor*. In bibliographical works, *editio princeps* signifies the earliest printed edition of an author; *editio optima*, that which is generally regarded as the best, &c.

E'DITORS, are of different species:—1. Those who merely republish a text, or content themselves with adding notes and commentaries to it. 2. Those who superintend the publication of a work, receiving the manuscripts from one or more contributors; seeing that the object of the work is attained, that the language is correct, the illustrations appropriate, and the facts accurately stated, and that all the parts of the work are properly adjusted and made subordinate to each other.

E'DRIOPHTHA'LMA. (Gr. ἑδϱαιος, *fixed*, and ὀφθαλμος, *an eye*.) The name under which the Malacostracous Crustaceans with sessile eyes are grouped together.

EDUCA'TION (Lat. educare), in its most extended signification, may be defined, in reference to man, to be the art of developing and cultivating the various physical, intellectual, and moral faculties; and may thence be divided into three branches—physical, intellectual, and moral education. This definition is by no means complete; but it is used merely as indicative of the manner in which this subject has generally been discussed. Under physical education is included all that relates to the organs of sensation, and the muscular and nervous system. Intellectual education comprehends the means by which the powers of the understanding are to be developed and improved, and a view of the various *branches of knowledge* which form the objects of instruction of the three departments into which we have divided education. Moral education embraces the various methods of cultivating and regulating the affections of the heart.

The wide extent of this subject, and the infinity of collateral questions with which it is mixed up, would prevent us from entering into any details respecting it, even if the difficulty of communicating any satisfactory information upon so boundless a theme within our limits did not preclude us from the attempt. The influence which education has exercised in humanizing the world is universally acknowledged. Its importance has been recognized by philosophers and legislators in every age; and by all the nations, both of antiquity and modern times, which have become distinguished in history, it has been regarded as the chief element in the attainment and promotion of civilization. The reader will find, in the writings of Plato, Plutarch, and Quintilian, among the ancients, and in modern times of Locke, Rousseau, Basedow, Niemeyer, Rehberg, Cousin, &c., a view of the chief systems that have been proposed or adopted in reference to this subject; and for an account of the comparative merit of the different systems, and the innumerable controversies that have been maintained in regard to them, he may consult the *Edin.* and *Quar. Reviews*, passim, and the other periodical publications of England.

EDU'LCORA'TION. (Lat. edulcoro, *I purify* or *sweeten*.) A chemical term applied to the cleansing of substances, especially pulverulent precipitates, by the repeated affusion of water, so as to remove all soluble matters, and render them free from taste and smell.

EFFE'CT. (Lat. efficio.) In the Fine Arts, that quality in works of art whose nature is to give particular efficacy to other qualities, so as to bring them out and to attract the eye of the spectator.

EFFECT. *See* KEEPING.

EFFE'NDI. A Turkish word signifying *lord* or *superior*; applied to legal, ecclesiastical, or other *civil* functionaries, in contradistinction to *aga*, the name by which high *military* personages are designated. *See* REIS EFFENDI.

EFFERVE'SCENCE. (Lat. effervesco.) The escape of gaseous matter from liquids, as in the act of fermentation. All liquids from which bubbles of gas rapidly escape, so as to resemble boiling, are said to effervesce.

E'FFIGY. (Lat. effigies.) In Painting and Sculpture, the representation of an individual.

EFFLORE'SCENCE. (Lat. effloresco, *I flower*.) The spontaneous crumbling down of transparent crystals in consequence of the loss of water.

EFFLU'VIUM. (Lat. effluo, *I spread abroad*.) The vapours arising from putrefying matters.

EFFU'SION. (Lat. effundo, *I pour out*.) In Surgery, the escape of a fluid from the vessel naturally containing it; thus when the chest is wounded blood may be effused into the cavity of the pleura, and in injuries of the head blood may be effused upon the brain.

EGEON. *See* PONTOPTULUS.

E'GERAN. A variety of garnet found near Eger in Bohemia.

EGG. (Germ. ei.) The ovum of birds and oviparous animals. The changes which the hen's egg undergoes during incubation have been described by Sir E. Home in the *Philosophical Transactions* for the year 1822 (page 339.), and illustrated by a beautiful series of plates after Bauer's drawings: the same volume also contains a valuable paper by Dr. Prout on the same subject, but chiefly in reference to the chemical changes of the egg during that process. The specific gravity of new-laid eggs at first rather exceeds that of water, varying from 1080 to 1090; but they soon become lighter, and swim on water, in consequence of evaporation through the pores of the shell. When an egg is boiled in water, and suffered to cool in the air, it loses about 32 hundredths of a grain of saline matter, together with a trace of animal matter and free alkali. The mean weight of a hen's egg is about 875 grains, of which the shell and its inner membrane weigh 93·7 grains, the *albumen* or white 529·8 grs., and the yolk 251·8 grs. The shell contains about 2 *per cent.* of animal matter and 1 *per cent.* of the phosphates of lime and magnesia, the remainder being carbonate of lime, with a trace of carbonate of magnesia. When the yolk of a hard-boiled egg is digested in repeated portions of strong alcohol, there remains a white residue having the leading characters of albumen, but containing phosphorus in some peculiar state of combination: the alcoholic solution is yellow, and deposits a crystalline fatty matter, and when distilled leaves a yellow oil. The albumen of the egg contains sulphur. The use of the phosphorus is to yield phosphoric acid to form the bones of the chick; but the source of the lime with which it is combined is not apparent, for it has not been detected in the soft parts of the egg, and hitherto no vascular communication has been discovered between the chick and the shell.

The trade in eggs is of great value and importance; the number of eggs imported into this country from various parts of the Continent, for the year ending Jan. 5. 1839, was 83,745,723; and the gross amount of duty received for the same was 29,111*l*.

E'GLANTINE. (Fr. eglantier.) The old English name of the sweet-briar rose. The term is improperly applied by Milton to the honeysuckle.

EGYPTIAN ARCHITECTURE. *See* ARCHITECTURE.

EGYPTIAN BEAN. The fruit of the *Nelumbium speciosum* has been so called: it has been regarded as the forbidden bean of the disciples of Pythagoras.

EGYPTIAN PEBBLE. A species of agate or jasper.

EI'DER-DUCK. The species of duck tribe so called is one of the largest and most valuable of the *Anatidæ*, and, from certain modifications of the beak and sternum, constitutes the type of a subgenus, called *Somateria*. The common eider (*Somateria mollissima*) frequents in great numbers the Orkneys, Hebrides, and Shetland isles. It is defended from the cold of the dreary northern coasts by the development of an unusual quantity of the finest down beneath the dense exterior plumage, which is equally well adapted to form an impenetrable barrier to the wet. The down of the eider constitutes its chief value, as it combines with its peculiar softness, fineness, and lightness so great a degree of elasticity that the quantity of this material which might be compressed and concealed between the two hands will serve to stuff a coverlet.

As the female plucks from her own body a quantity of her finest down to line her nest, the Orcadians avail themselves of this instinct, and take an early opportunity to rob the nest of both eggs and down. She then begins to lay afresh, and envelops her eggs with another layer of down; and if this be removed, the male is said to contribute his own down when the female can afford no

more. Lastly, when the brood of ducklings is hatched, the nest is again visited and the down removed. Thus a considerable quantity of the valuable material furnished by the eider-duck is obtained independently of that which is plucked from the slaughtered birds. Besides the down and eggs, the islanders turn the skins and flesh of the eiders to profit; while these birds cost them no expense, as they feed entirely on sea-weed and other natural productions of the ocean.

EISTE'DDFOD. (Welsh, from eistedd, *to sit.*) The assemblies or sessions of the Welsh bards were so termed. (*See* BARD.) They were held, according to Pennant (*Tour in Wales*), at different places for the minstrels of their respective neighbourhoods; at Caerwys, at Aberfraw in Anglesea, and Mathravel in Powys. The judges were appointed by commissions from the Welsh princes, and after the Conquest from the English kings. The last was issued in 1568. But the Gwynnedigion and Cambrian Societies have lately revived the old custom; and annual meetings for the recitation of prize poems, and for performances on the harp, are now held under the name of Eisteddfod.

EJE'CTMENT, in Law, is a personal action in the form of trespass, in which a tenant for years claims damages for his expulsion from land demised to him; and it has become the usual form of trying questions of right to real property by a singular fiction. The party claiming land or its appurtenances not in his possession is the real plaintiff, through the means of a fictitious tenant (the celebrated John Doe), who complains of being ejected from his farm by the defendant. The defendant justifies by disputing the plaintiff's title to let the land; and if the plaintiff succeeds, he recovers not only *nominal* damages for his ejectment, but also *the land itself* for the term of Doe's supposed demise, and in fact for the term of his own right.

ELÆAGNA'CEÆ. (Elæagnus, one of the genera.) A natural order of shrubby arborescent Exogens inhabiting the entire northern hemisphere down to the equator, having leprous leaves, superior fruit, tubular calyx, and apetalous flowers. They are distinguished from *Thymelaceæ* by the ovule being erect, from *Proteaceæ* by the valvate calyx and the dehiscent fruit of the latter, and from *Santalaceæ* by the superior ovary. The berries of some species are eaten in Persia and Nipal.

ELÆOTE'RIUM. (Greek. ἔλαιον, *oil.*) In Ancient Architecture, an apartment in the ancient baths wherein the bathers anointed themselves after leaving the bath.

ELAI'DIN. A fatty matter produced by the action of nitric acid upon certain oils, especially upon castor oil.

ELAI'N. (Gr. ἔλαιον, *oil.*) That portion of fat or oil which retains a liquid state; it may be pressed out of hog's lard and other solid fats, and separated from oils by exposing them to cold and subsequent pressure.

ELAIO'DIC ACID. (Gr. ελαιον, and ειδος, *form.*) One of the compounds produced during the saponification of castor oil.

E'LAOLITE. (Gr. ελαιον, and λιθος, *stone.*) A brittle mineral, of a greasy lustre, crystalline in its texture, of various shades of grey, green, and red, and composed of silica and alumina, with about 18 *per cent.* of potash. It is found in Norway, and when *chatoyant* is sometimes used for ring stones.

E'LAPS. A subgenus of vipers. *See* VIPERA.

ELA'SMOTHE'RIUM. (Gr. ελασμος, *a plate*, and θηρ, *a beast.*) The name of an extinct Pachydermatous animal, which forms the type of a new genus, characterized by the laminated structure of its teeth, and intermediate between the horse and rhinoceros.

ELASTI'CITY. (Gr. ἐλαστη, *a spring;* from ελαυνω, *I draw.*) In Physics, that property which certain bodies possess of recovering their primitive form and dimensions after the external force by which they have been dilated or compressed or bent is withdrawn.

The theory of elasticity must be deduced from some hypothesis respecting the constitution of matter. The simplest and most general view which can be taken of the subject is, that all matter is composed of indefinitely small parts or *molecules* acted upon by attractive and repulsive forces. The attractive forces result from the action of the molecules on each other; the repulsive forces from the caloric with which the molecules are combined. From the combined action of these two forces, the attraction of matter and the repulsion of caloric, the different forms of matter and its varied physical properties may be explained.

This view of the constitution of bodies supposes that the molecules are not in contact, but at a certain distance from each other, which, though it is to be regarded as infinitely small in comparison of any distance appreciable by our senses, admits nevertheless of increase and diminution. When a body is in a state of rest, the opposite forces which any two of its contiguous molecules exercise on each other are in equilibrium. The energy of the forces also depends on the distance between the two molecules, or, in mathematical language, is a function of that distance. If the distance be increased within the limits of the action of the forces, both forces are diminished; and if the distance is diminished, both are increased, but not in the same proportion. If the interval at which the two forces balance each other be diminished, the repulsive force becomes stronger than the attractive force, and the two molecules are repelled from each other: on the contrary, if the distance be increased, the attractive force acquires the superiority, and the molecules are drawn towards each other.

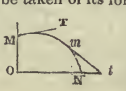
Let us now suppose a solid body, of which all the molecules are in a state of equilibrium, to receive the impression of an external force. The operation of the force is to produce a change in the distances of the molecules at the surface, in consequence of which the equilibrium is disturbed, and the molecules thrown into a state of vibration. This vibration is communicated to the interior molecules; and the body, under the action of the external force, undergoes a certain change of form. The molecules at the surface, which receive the impulse, transmit it to those in the interior of the body, and are reacted on by them with an equal force. In this manner the action is propagated through the whole mass, until it is destroyed by another exterior force, or by the resistance of an obstacle to the motion of the body itself.

From this hypothesis respecting the constitution of matter, analytical expressions may be deduced to represent the motions or the equilibrium of the molecules of a body acted upon by an external force which is not so great as to exceed the limits of its elasticity, or to produce a change in the distance of the molecules greater than the radius of the sphere of molecular action. These equations contain a numerical coefficient, which is constant for the same body, but variable for different bodies: and which has no influence on the law of elasticity, though it serves to measure its effects. It is therefore called the *modulus* of elasticity, or *coefficient* of elasticity; and is of the same nature and order of magnitude as the cohesive resistance which bodies oppose to rupture on being crushed, and may therefore be expressed as so many pounds acting on a square inch of surface. The modulus of elasticity for each particular body must be determined by experiment, and has only been ascertained in a few instances.

Elasticity is perfect when the body exactly recovers its primitive form, after the force by which it is bent or compressed or dilated has been removed, in the same time as was required for the force to produce the alteration. This perfect elasticity is, however, not found in any of the bodies of nature; the aëriform fluids or gases are those whose elasticity approaches the nearest to it. Hard bodies, even tempered steel and ivory, possess it in a less degree; in fluid substances the elastic force is greatly diminished; and in soft bodies, as butter, moist clay, it entirely disappears. In solid bodies the elastic force is, in general, diminished by use, or by a long-continued application of a straining force. A bow which has been long bent, or a spring which has been long compressed, will not entirely recover its original form. In many cases the elasticity of a body can be augmented by producing a closer aggregation of the molecules. The metals, for example, are rendered more elastic by hammering them cold, or by alloys. Iron and steel acquire a greater elasticity by *tempering;* that is, by producing a sudden contraction of their volumes when they have been expanded by heat.

The principal phenomena of elastic bodies are the following: — 1. That an elastic body (the elasticity being supposed perfect) exerts the same force in endeavouring to restore itself as that with which it was compressed or bent. 2. The force of elastic bodies is exerted equally in all directions, but the effect chiefly takes place on the side on which the resistance is the least. 3. When an elastic solid body is made to vibrate by a sudden stroke, the vibrations are performed in equal times, to whatever part of the body the stroke may be communicated. Thus, sonorous bodies always emit sounds of the same pitch; and the difference of the pitch depends on the greater or less frequency of the vibrations of the sonorous body. 4. A body perfectly incompressible cannot be elastic, therefore bodies perfectly solid can have no elasticity; and hence, also, the small degree of elasticity belonging to the liquids which are eminently incompressible. *See* COLLISION, PERCUSSION, STRENGTH OF MATERIALS; also ATMOSPHERE, HYDRODYNAMICS, PNEUMATICS, and VAPOUR.

ELA'STIC CURVE. In Mechanics, the figure assumed by an elastic plate or lamina, one end of which is fixed horizontally in a vertical plane, and the other loaded with a weight which tends by its gravity to bend the plate. This was the manner in which the curve was conceived to be formed by James Bernoulli, who first investigated its properties; but a more general view may be taken of its formation. Let the lamina M N be fixed



at the point M in such a manner that, however it may be bent, the direction of the tangent M T shall be constant; and let it be submitted to the action of any number of forces acting in the same plane, which will be the plane of the curvature. Let P be the resultant of all the forces acting

in the direction O M, the axis of y, and Q the resultant of all those acting in the direction O N, the axis of x; and let the distances of the directions of the forces P and Q from the axes of the co-ordinates be respectively p and q. The curve at any point m, the co-ordinates of which are x and y, is kept in equilibrio by the action of three forces, namely, P and Q, which are exerted in turning the lamina round the point m, and the elasticity E, which may therefore be considered as acting in the direction perpendicular to $m\ t$, the tangent at m. But the action of P on the point m is equal to the product of that force by its distance from the ordinate of m parallel to its direction, which distance is $p-x$. The action of P is therefore equal to $P\ (p-x)$; and, in the same manner, the action of Q is equal to $Q\ (q-y)$. Hence, since the elasticity is equal to the sum of these two, we have the equation

$$P\ (p-x) + Q\ (q-y) = E.$$

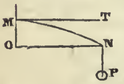
It is now necessary to make a hypothesis respecting the manner in which the elasticity E varies from point to point in the curve. The law usually assumed is, that the force of elasticity at any point is proportional to the tension, or inversely as the radius of curvature at that point; hence if r denote the radius of curvature, and E be the elasticity at the point where $r = 1$, the general equation of the elastic curve becomes

$$P\ (p-x) + Q\ (q-y) = \frac{1}{r}\ E.$$

Let $f'x = \frac{d\,y}{d\,x}$, and $f''x = \frac{d^2\,y}{d\,x^2}$; then, by the known expression for the radius of curvature, we have $\frac{1}{r} = \frac{f''\,x}{(1+f'x^2)^{\frac{3}{2}}}$.
The differential equation of the curve therefore becomes

$$P\ (p-x) + Q\ (q-x) = \frac{E\,f''\,x}{(1+f'\,x^2)^{\frac{3}{2}}}.$$

To take a simple case, let us suppose the lamina so



situated that the tangent M T is parallel to the axis O N, in which situation the force Q vanishes; and also let the force P be that resulting from the gravity of a weight suspended from the extremity N of the lamina; then, if $l =$ the length of the lamina, we shall have

$$P\ (l-x) = \frac{E\,f''\,x}{(1+f'\,x^2)^{\frac{3}{2}}}.$$

Let us further suppose the curvature to be very small, in which case, $f'\,x = \frac{d\,y}{d\,x}$ will be very small, so that its square may be neglected. We have then, on substituting for $f''\,x$ its value,

$$P\ (l-x) = E\,\frac{d^2\,y}{d\,x^2}.$$

The integral of this is

$$P\ (l\,x - \tfrac{1}{2}\,x^2) = E\,\frac{d\,y}{d\,x};$$

and a second integration gives

$$y - k = \frac{P}{2 \cdot 3\,E}\ (3\,l\,x^2 - x^3),$$

k being a constant, and equal to the distance O M.

The elastic curve is the same as that which a perfectly flexible line would form itself into, if supported at its two extremities and loaded with a fluid of uniform density filling the whole cavity of the curve; or it is the figure assumed by a spider's thread fixed at its extremities and blown by the wind.

E'LATER. (Gr. ελατηρ, *leaper*.) A Linnæan genus of Coleopterous insects, now the type of an extensive family of the Serricorn Coleoptera. The *Elateridæ* may be distinguished from the other Serricorn beetles by the presence of a strong, short, and often slightly curved spine, projecting from the posterior margin of the prosternum, and of a depression just above the origin of the second pair of legs adapted for the reception of the preceding spine. An *Elater* may be recognized on a distant view from the particular use to which it puts the above described sternal modifications. If a beetle be seen to fall upon its back, and instead of making the ordinary attempts to set itself upon its legs, bends its head towards its tail, raising this part, and then suddenly springing into the air, and repeating the action until it has fallen upon its feet, such a beetle may be recognized at once as a species of one or other of the numerous subgenera of the *Elateridæ*. This leap is due to the rebound occasioned by the sudden disengagement of the sternal spine from its socket. One of the species of *Elater* proper (*Elater noctilucus*) is the common fire-fly of the tropical parts of America. Its luminosity is emitted by two round convex yellow spots situated at the sides of the thorax. The *Elateridæ* generally are vegetable feeders; the larvæ devour decayed timber; the perfect insects feed on flowers or other soft and living parts of vegetables.

ELA'TERES. In Botany, the loose spiral fibres that are contained, together with the sporules, in the conceptacles of *Jungermaunia* and *Morchantia*.

ELATE'RIUM. (Gr. ελαυνειν, *to stimulate*.) This substance, commonly called *extract of elaterium*, is obtained from the fruit of the *Momordica elaterium*, or *squirting cucumber*, which, if gathered a little before it ripens and the juice gently expressed, deposits a green sediment, which is collected and dried. In the dose of from one eighth of a grain to a grain, good elaterium operates as a drastic purge, bringing away from the bowels a large quantity of watery secretion; it is seldom prescribed except with a view of diminishing the collection of fluid in cases of dropsy.

Elaterium. In Botany, a term invented by Richard to denote that kind of fruit which is found in *Euphorbia*, consisting of three or more carpels, consolidated when young, but bursting with elasticity when ripe.

E'LBOW. The sea phrase for the half twist in the cables by which the ship is moored, caused by her *swinging* the wrong way. (*See* Hawse.) Also a term for a sudden turn in a line of coast or course of a river.

ELBOWS. (Sax. elboga.) In Architecture, the upright sides which flank any panelled work, as in windows below the shutters, &c.

ELCA'JA. An Arabian tree, the fruit of which is emetic, and is employed in an ointment for the cure of the itch: it is the *Trichilia emetica* of botanists.

E'LDERS. Certain laymen who, according to the constitution of the Presbyterian church, form a council of which the minister is the moderator, and discharge the functions of a spiritual court. They also assist the minister in the management of the concerns of the parish, attending to the interests of the poor, like the deacons of the primitive church. Among the Jews, elders were those persons most distinguished for age, rank, and wealth, who formed the council of the people. *See* Presbyters.

EL DORA'DO. (Span. *the golden region*.) The name given by the Spaniards to an imaginary country, supposed in the 16th century to be situated in the interior of South America, between the rivers Orinoco and Amazon, and, as the name implied, abounding in gold and all manner of precious stones. After the Spanish conquest of Mexico and Peru, the most exaggerated accounts of the wealth and riches of the newly acquired territory were circulated and believed. A new region was fabled to exist far surpassing the wealth and splendour of Peru; expeditions were fitted out for the purpose of discovering it; and though all such attempts proved abortive, the rumours of its existence continued to be believed down to the beginning of last century. The term has now passed into the language of poetry, in which it is used to express a land of boundless wealth and felicity, like the ancient Elysium or the Mohammedan Paradise. (See a learned article on "Sir Walter Raleigh" in vol. lxxii. of the *Edin. Review*, which contains a *resumé* of all the speculations that have been entertained upon this subject.

ELEA'TIC PHILOSOPHY. A system owing its origin to Xenophanes, a native of Elea (in Latin *Velia*), who lived about the year B.C. 530. The most celebrated of his followers were Parmenides and Zeno, also natives of Elea. The dialectical character of the principal systems of antiquity may be said to owe its existence to the Eleatics. The tendency of their speculations was the direct contrary of that which distinguishes the Ionic school. While the latter fixed their attention on outward nature, and strove to discover the laws which regulate its progress, Xenophanes and his disciples confined their thoughts to what they conceived to be the only objects of real knowledge — the ideas of God, or Being as it is in itself. The world of succession and change, which they designated under the title of *that which becomes* (τὸ γιγνόμενον), they held to be utterly vain and illusory; the very conception of change itself seeming to them to involve a contradiction. Time, space, and motion they regarded as mere phantasms, generated by the deceiving senses, and incapable of scientific explanation. They were consequently led to distinguish between the pure reason, the correlative of Being, and in one sense identical with it, and opinion or common understanding, the faculty which judges according to the impressions of sense. Parmenides, in particular, was the author of a philosophical epic, the two books of which treated respectively of these two modes of thinking. For a full account of all that can be gathered from remaining fragments of this rigid system of rationalism, the reader must consult the German writers on the subject; in particular Brandis and Ritter, in their histories of philosophy. Frequent allusion is made both by Plato and Aristotle to the Eleatic doctrines, the authors of which are mentioned by both those philosophers in terms of evident respect and veneration. Plato has made their system the subject of a whole dialogue, entitled the *Parmenides*; perhaps the most striking specimen of dialectic subtlety which Grecian philosophy affords. Many valuable remarks on the nature and influence of the Eleatic doctrines are to be met with in Mr. Thirlwall's *History of Greece*, vol. ii. c. 12.

ELECA'MPANE. The vulgar name of the *Inula*

Helenium. It is an aromatic bitter, and was formerly regarded as expectorant; whence the monkish line,

Enula campana reddit præcordia sana.

A coarse candy, composed of little else than coloured sugar, is sold under the name of elecampane.

ELE'CT. (Lat. electus.) Some functionaries are so termed during the period between their appointment and some act which is necessary to ratify it; as, a bishop after election and before consecration.

ELE'CTION, in Law, is when a man is left to his own free choice to take or do one thing or another, which he pleases; as, where a man has two forms of action by which he may recover his right, it is within his election to choose that according to which he will proceed; or where, as in some cases, he has an election between several parties, against any of whom he may prosecute his suit. Where there are coparceners of lands, on partition the eldest sister has the election.

ELE'CTION, in Theology, is the choice made by God of certain individuals of the human race to enjoy peculiar privileges and blessings. In the Old Testament election is spoken of as national, not individual. The Jews were the chosen people of God (Deut. iv. 37., Is. lxv. 9., and in passages too numerous to be cited). And that the "elect" or chosen of God, of whom the inspired writers of the Epistles speak, and to whom they often address themselves, are in some instances only persons called to partake in the benefits of the Christian dispensation, appears to be admitted on all hands (1 Pet. i. 1, 2.; 1 Pet. ii. 9.). But an opinion arose from very early times in the church, that in other passages (Rom. ix. 18. 24., Eph. 1, &c.) the election spoken of is a predetermined choice, not to the immediate blessings of the covenant, but to eternal life; that God, by arbitrary will, selects a number of persons without respect to foreseen faith or good works, and infallibly ordains to bestow upon them eternal happiness through the merits of Christ. This doctrine is of course opposed to that of universal redemption; namely, that every man is enabled (if he will) to obtain salvation through those merits. It is certain that the doctrine of election — something resembling which is attributed to the Basilidians, Valentinians, and other early heretics — cannot easily be traced in the writings of any father of the church before Augustine, who embraced it with all the ardour of his eager disposition, but appears to have varied much in his opinions respecting it. It is most rigidly laid down in his treatise *De Dono Perseverantiæ*. Calvin, in modern times, was its great reassertor, and declared it in a dogmatical manner: "We were elected from eternity, before the foundation of the world, from no merit of our own, but according to the purpose of the divine pleasure." (*Inst.* iii. c. 15. s. 5.) It became a fundamental article of belief in Calvinistic churches. The synod of Dort was expressly convened to vindicate the doctrines of election and predestination against Arminian tenets (1615). The language of the Church of England, on this as on other controverted points, admits of a variety of interpretations; but during the prevalence of Calvinism in the higher clergy, and especially in the university of Cambridge, under Archbishop Whitgift, an attempt was made to define her tenets more strictly. The Lambeth articles, agreed to in 1595 by a portion of the clergy, assert that "God from eternity hath predestinated certain men unto life, certain he hath reprobated." But these were never authentically received by the church. *See* CALVINISM, PREDESTINATION.

ELECTIVE AFFINITY signifies the order of preference, as it were, in which substances combine; thus, if nitric acid be added to a mixture of lime and magnesia, it will *elect* or choose to combine with the lime in preference to the magnesia. *See* AFFINITY, CHEMICAL.

ELECTIVE GOVERNMENTS are those in which all functionaries, from the highest to the lowest, are chosen by the suffrages of a greater or less number of citizens. Of these the government of Athens in antiquity, and in modern times that of the United States, will serve as examples. When the functionaries of an elective government are chosen by a very great number, it is identical with a democracy; and when by a comparatively small number, either with an aristocracy or an oligarchy.

ELE'CTORS. (Germ. chur- or kur-fürsten.) Those princes of the old German empire who had a voice in the election of the emperor. These were originally (A. D. 1256) seven: Mentz, Treves, and Cologne, — ecclesiastical; and Bohemia, Brandenburg, Saxony, and the Elector Palatine, — lay; but to these Bavaria was added soon after their institution. In 1692 this dignity was conferred on the dukes of Brunswick-Luneburg, who were afterwards styled electors of Hanover; and, at different periods during the last century, on the princes of Salzburg, Wurtemberg, Baden, and Hesse Cassel. But on the dissolution of the German empire in 1806, the title of elector was merged in that of king, grand duke, &c. &c., by all the German states except Hesse Cassel, whose sovereign is still designated elector. The electors had various privileges, both general and special.

ELE'CTRIC FISHES. The species of the class *Pisces* are so called which have the power of discharging electric shocks; the most remarkable are the *Torpedo*, *Gymnotus*, and *Silurus*, or *Malapterurus electricus*.

ELECTRI'CITY. (Gr. ηλεκτρον, *amber;* the substance in which the property of attracting light substances after friction was first observed.)

This truly extraordinary power of matter, independent of the interest that always belonged to it, has of late years acquired much importance from its influence over chemical phenomena, and its connection with those of magnetism. When a clean glass tube is rubbed with the dry hand, or with a piece of silk, it attracts and repels any light substances, — such as feathers, bran, or little pieces of paper, — which are brought near it; a stick of sealing wax rubbed upon dry flannel exhibits the same appearances, and, to a superficial observer, seems to be exactly in the same state as the glass; and they are said to be electrically *excited*. But, on more close examination, it is found that when light bodies are *attracted* by excited glass, they are *repelled* by excited sealing wax, and *vice versâ*, so that the glass and wax are said to be in *opposite electric states;* and hence the terms *vitreous* and *resinous* or *positive* and *negative* electricity. But these two states are always coexistent: thus when glass is rubbed by silk the glass becomes positive, but the silk becomes negative; and in the case of sealing wax rubbed by flannel the wax is negative, but the flannel is positive.

A similar excitation of electricity is seen in an infinity of other cases; as when we rub a cat's back with the hand, or when a piece of silk riband is drawn briskly between the fingers, or a sheet of paper rubbed with India-rubber, or a metal rod with a silk handkerchief. These, and other extraordinary phenomena connected with them, are hypothetically referred to the presence of a peculiar form of matter called the *electric fluid;* it is supposed to appertain to all matter, but to become evident only when in redundance or deficiency. When glass is rubbed with silk the equilibrium of the electric fluid is disturbed, the silk imparts it to the glass; and hence the former, losing electricity, becomes *minus* or negative, and the latter, acquiring electricity, becomes *plus* or positive. This is commonly called "Franklin's Theory," having been proposed and defended by that celebrated electrician. Others have assumed the existence of *two fluids* as essential to the explanation of electrical phenomena; both equally subtile, elastic, and universally diffused, and each highly repulsive as to its own particles, and attractive of those of the opposite kind. Electrical quiescence is referred to the combination of these fluids, and their consequent mutual neutralization; and electrical excitation is the consequence of either being free or in excess. It is supposed that they are separated by friction, and by all those other causes which give rise to the appearance of free electricity. Either of these hypotheses may be adopted as facilitating the explanation of electrical phenomena, and as conferring meaning on terms which would otherwise be unintelligible: of the two the simplest, or that which refers the phenomena to one fluid, is perhaps the most generally applicable. Both are apparently equally consistent with facts; but the existence of any *fluid*, or form of matter, as the cause of electrical phenomena, is at best extremely problematical.

There are two series of distinct phenomena presented by electrified bodies: the one seems to result from the accumulation of electricity upon the surfaces of bodies; they are commonly included under the term *electricity of tension*, and are well exhibited by the common electrical machine and its prime conductor. It affects all neighbouring bodies, and they are thrown by it into a polar electrical state by what is termed *induction:* it has a tendency to pass off in sparks through the air, or gradually to escape from points. The thunder storm furnishes a magnificent specimen of this state of electricity. The other state of sensible electricity is that exhibited by *electricity in motion;* as when a current of electricity is passing through a wire or other conducting medium: in this case a vast *quantity* of electricity may be concerned in the phenomena without any apparent *intensity;* but, whilst the current is continuous, it produces magnetic phenomena of a most extraordinary character; and, when the perfect conductor is broken by the intervention of certain other media, they suffer in some cases chemical decomposition, and in others become heated, and even ignited. The phenomena of electricity in motion are best exhibited by the Voltaic apparatus.

In all electrical experiments remarkable differences are observed in respect to the transfer of the electric fluid through different bodies: some, such as the metals, allow its free and nearly unimpeded passage through their substance; while others receive and retain it more superficially, such as glass, resin, and other substances which exhibit attractive and repulsive powers when rubbed. Hence the division of bodies into *conductors* and *non-conductors*.

Many most important electrical phenomena depend apparently upon *induction*, a subject which has been ably

studied by Faraday. (*Phil. Trans.*) We shall here enter into such details only as are required to render some of the principal terms employed in discussing electrical phenomena intelligible.

If P + represent a metallic sphere in a highly positive electric state, and N P a metallic *conductor* in its vicinity *insulated* upon a glass stem; it will be found that the extremity N of N P is *negative*, whilst the other extremity P is *positive*, and that these opposite electricities are greatest at the extremities of the conductor, and gradually diminish towards the centre line C, which is neutral. This extraordinary state of excitation in N P is entirely dependent upon the proximity of P+; for if P+ be withdrawn, N P loses all appearance of electricity; and the degree of excitement in it is directly proportional to the extent to which P+ is excited, and (within certain limits) to its nearness to N; so that fluctuations in the electricity of N P will be observed in proportion as P+ is brought towards or removed from N, provided they are not brought into *contact*, and that no *spark* passes. These phenomena have been theoretically explained upon the supposition that the free electricity in P+ disturbs the equilibrium of the natural electricity of N P, and by repelling it from N to P leaves the former *minus* and the latter *plus*. Or, if we assume the existence of two electric fluids, then the free positive electricity of P+ *repels* the positive fluid of N P and *attracts* its negative fluid, throwing it into an *electro-polar* state. If N P, instead of being insulated, be connected by its extremity P with the ground, the accumulation at P is prevented whilst N retains its deficient or negative state; or, upon the other theory, the positive fluid at P is neutralized by a supply of negative fluid from the earth; and if, after having effected this by momentarily touching N P with the finger, we suddenly remove P+, the insulated conductor N P will be left with an excess of negative electricity.

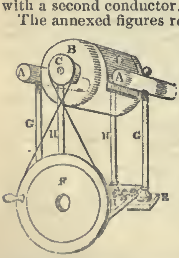
It will be obvious from the above statement that when light bodies, especially if they be conductors, are attracted by electrified surfaces in their vicinity, they are thrown by induction into opposite electrical states; and when the hand is brought near the excited conductor of the electrical machine, it becomes negative, and remains so till the equilibrium is restored by the passage of a spark; which phenomenon is supposed to be the result of the combination of the two electric fluids.

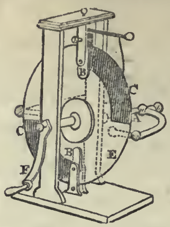
Many important phenomena of electrical accumulation are explained by reference to the principles of induction, and among them the action of the *Leyden jar* or phial. A thin glass jar or bottle, A, is coated inside and out, to within three or four inches of its mouth, with some conducting substance; tin foil, being especially convenient for the purpose, is generally used; and a metallic rod projecting a few inches from the aperture, and surmounted by a brass ball, B, communicates with the interior coating.

When the ball is applied to the prime conductor of the electrical machine, and the outer coating communicates with the ground, the interior acquires a positive and the exterior a negative charge; and on making a communication by means of a conductor between the inner and outer coatings, the electricities are annihilated with the production of a bright spark and explosion, and by a most disagreeable sensation, called the *electric shock*, if the body be made part of the *circuit*. When several jars are so arranged that their interior and exterior coatings are all separately connected, the assemblage constitutes the *electrical battery*.

In the common *electrical machines*, electricity is excited by the *friction* of the plate or cylinder of glass upon the cushions or rubbers; and the glass becomes positive, and communicates the same state to the opposed conductor, generally termed the *prime conductor* of the machine; the rubber becomes negative, and is sometimes connected with a second conductor.

The annexed figures represent the two common forms of the electrical machine. The first is the *cylinder* machine, commonly called Nairne's machine. B is the glass cylinder, which is made to revolve upon its axis by the multiplying wheels F, C, the necessary friction for the electric excitation being produced by the cushion and silk flap D. A A are the positive and negative conductors: the latter, bearing the cushion, is adjusted as to its requisite pressure upon the cylinder by the screw at E. The conductors are respectively supported and insulated by the glass pillars G G, which should be coated with lac varnish; and the axis of the cylinder rests upon the pillars H H, which are also of glass. The second figure represents the *plate* machine, usually termed Cuthbertson's machine, in which A is the prime conductor, borne by a stout glass stem which is attached to the frame of the machine. B B are the upper and lower pairs of cushions, by which, together with the silk flaps C C, the necessary friction is obtained. E is the disk of plate glass which is made to revolve upon its axis by the winch F. In this machine, as the cushions or rubbers are not insulated, the negative electricity cannot be separately accumulated or exhibited, as in the cylinder machine.





There are many other and highly important causes of electric excitation than those above adverted to; such as contact of different metals (*see* GALVANISM), chemical action (*see* VOLTAIC ELECTRICITY), change of temperature (*see* THERMO-ELECTRICITY), and magnetism (*see* MAGNETISM and ELECTRO-MAGNETISM).

ELE'CTRO-CHEMISTRY. That branch of chemical science describing the especial applications of electricity as a chemical agent.

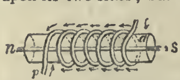
ELE'CTRODE. (Gr. ηλεκτρον, and ὁδος, *a way*.) The surfaces by which electricity passes into and out of other media have been called by Mr. Faraday *electrodes*. The term has also sometimes been derived from ηλεκτρον, *amber*, and ειδος, *like*, and applied to substances which, like amber, become electric by friction.

ELE'CTRO-DYNA'MICS. (Gr. ηλεκτρον, and δυναμις, *power*.) The phenomena of electricity in motion.

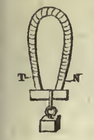
ELE'CTROLYTE. (Gr. ηλεκτρον, and λυω, *I set free*.) Substances susceptible of direct decomposition by the action of the electric current: hence, also, the verb *electrolyze;* i.e. to resolve compounds into their elements by the agency of electricity. Faraday has shown that in many supposed cases of electrolysis, the evolution of elements is the consequence of a secondary action; the sulphur, for instance, which is thus evolved at the negative pole from sulphuric acid, is the result of the evolution of hydrogen at that pole; in all cases of true electrolytic action sulphur appears at the anode.

ELECTRO-MAGNETISM. When a current of electricity is traversing any substance, or when electricity is in motion, magnetism is at the same time developed. This fact was first observed by Professor Oersted of Copenhagen, and has become the source of an important series of discoveries included under the above term. The excitation of magnetism depends upon *quantity* of electricity, and is best observed in the wire which closes the voltaic circle, especially of one or more pairs of large plates. If a magnetic needle be brought near a wire through which an electric current is passing, it will immediately deviate from its usual position, and assume a new one, dependent upon the relative position of the needle and the wire. On placing the electric wire *above* and parallel to the magnet, the pole next the negative end of the battery always moves to the west; and when the wire is placed *under* the needle, the same pole turns to the east. When the electric wire is on the same horizontal plane with the needle, no declination takes place; but the magnet shows a disposition to move in a vertical direction, the pole next the negative side of the battery being depressed when the wire is to the west of it, and elevated when it is to the east.

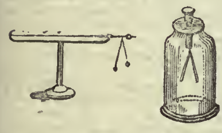
The magnetic phenomena of a wire transmitting electricity are such as appear to depend upon the circulation of magnetism at right angles to the electric current, so that if N P represent the wire transmitting a current of electricity in the direction of the horizontal darts, a current of magnetism will be established in the direction of the vertical dart, appearing to move round the axis of the electric current; hence the term *vertiginous* or rotary magnetism, applied to these phenomena; and hence the motion of the pole of the magnet round the electric wire, or of the electric wire round the pole of the magnet, when they respectively are so arranged as to be able to move freely in any direction. If a steel needle be placed in contact with the electric wire, and parallel to it, it acquires opposite magnetisms upon its two sides; but if it be placed at right angles to the connecting wire, it becomes polar, and permanently magnetic. If the electric wire be twisted into a spiral, and the steel needle placed within it (as in the cut), it is retained there, and becomes a more powerful magnet in consequence of the repetitions and direction of the electric and magnetic currents, as will be evident from the annexed figure, where *a* represents a glass tube with the



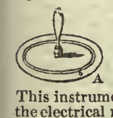
wire n p conveying the electric current twisted round it; the darts at the ends of which show the ingress and egress of the electricity, and the transverse darts the direction of the magnetic current. If the cylinder round which the wire conveying the electric current is twisted be of steel, it becomes a permanent magnet; if of pure soft iron, it becomes a temporary magnet, so long as the electric current is in motion, and s and n are powerfully opposed poles. If the bar be bent, as in the annexed cut, a powerful horse-shoe magnet is obtained when the ends p n of the copper wire twisted round it are connected with the voltaic circle; and a single pair of plates is sufficient for the purpose.



ELECTRO'METER. (Gr. ηλεκτρον, and μετρον, *a measure.*) An instrument for ascertaining the presence and intensity of electric excitation. The simplest form of electrometer consists of two very small pith balls suspended from a small conductor by very fine wire or thread; upon the principle that bodies similarly electrified repel each other, these *diverge* upon the reception of very minute quantities of electricity. Two thin slips of gold leaf are also similarly applied; and, to prevent the influence of the agitation of the air upon them, they are suspended in any convenient way under a glass shade. The other forms of electrometers generally act upon the same principle, being respectively adjusted to the varying degrees of quantity and intensity.



ELECTRO'PHORUS. (Gr. ηλεκτρον, and φερω, *I carry.*) This instrument consists of a flat smooth cake of resin A, which is rendered negatively electrical by friction; a plate of brass with a glass handle is then placed upon it, and becomes electropolar by induction. The brass plate, having been touched by the finger whilst lying upon the resin, is afterwards lifted off by its glass handle, and gives a spark of positive electricity. The same operation maybe indefinitely repeated. This instrument is sometimes a convenient substitute for the electrical machine, and is elegantly applied to inflame a jet of hydrogen gas in *Volta's inflammable air lamp.*



ELE'CTROPO'LAR. A term applied to conductors, one end or surface of which is positive, and the other negative; a state which they commonly exhibit when under the influence of induction.

ELE'CTROSCOPE. (Gr. ηλεκτρον, and σκοπεω, *I see.*) An instrument for rendering electrical excitation apparent by its effects. The gold leaf electrometer, and other similar arrangements, are *electroscopes.*

ELE'CTRUM. (Gr. ηλεκτρον.) A term applied by the ancients to various substances; but especially to the substance now called amber, or to a certain metallic alloy consisting of four parts of gold and one part of silver. (See *Pliny*, lib. xxxiii. and xxxvii.)

ELE'CTUARY. (Lat. electuarium.) This term is generally applied to powders which are mixed up with syrup, so as to be of about the consistency of treacle. The *confections* of the present Pharmacopœia are substituted for the former electuaries.

ELE'DONE. (Gr. ελεδονη.) A name applied by Aristotle to a genus of Malakia or Cephalopods having a single row of suckers on each arm, and without any musky odour; it is applied in modern zoology to the same genus.

E'LEGANCE. (Lat. elegantia.) In the Fine Arts, a quality indicating grace and lightness, but especially the latter. In painting and sculpture it greatly depends on good selection and delicacy of execution, and these again upon taste. Heaviness, and leanness or extreme lightness, are the boundaries between which elegance is a mean.

ELE'GIT (Lat. *he has chosen*), in Law, is a writ of execution, which lies for one who has recovered debt or damages; or upon a recognizance in any court against one not able in his goods to satisfy the same, directed to the sheriff, commanding him to make delivery of a moiety of the party's land, and all his goods except beasts of the plough. The creditor holding the moiety of the land until satisfaction is termed tenant *by elegit.*

E'LEGY, is the name given in modern times to a species of poetical composition of a mournful character. But though this signification of the term tallies with its etymology (Gr. ε, and λεγειν, *to cry alas*), the expression *elegy* among the Greeks, with whom it originated, and among the Romans, by whom it was assiduously cultivated, had a much wider signification. Thus among the former it embraced equally the warlike verses of Tyrtæus, the melancholy effusions of Mimnermus, and the moral and political aphorisms of Theognis and Solon; and among the latter it comprehended the miscellaneous themes of Ovid, Propertius, Tibullus, and Catullus. The form of verse in which it was composed was the alternate hexameter and pentameter. (*See* PENTAMETER.) In modern times almost all the nations of Europe have practised this species of composition; but if we except the *Elegies* of Hammond, Milton's *Lycidas*, and Gray's *Elegy* among ourselves, and Matthisson's *Elegie* among the Germans, it does not appear with great success.

E'LEMENTS. The old chemists applied this term to certain imaginary principles or essences of matter; such as fire, water, earth, and air. The elements of the alchemists are salt, sulphur, and mercury. The term element is now used as synonymous with *simple* or *undecompounded body;* that is, a substance which we cannot resolve into simpler forms of matter. The present list of *elements* includes all the *metals*, and the following substances — oxygen, chlorine, iodine, bromine, fluorine, hydrogen, nitrogen, sulphur, phosphorus, carbon, selenium, and boron; amounting in all to fifty-four, exclusive of the imponderable forms of matter. *See* EQUIVALENTS, CHEMICAL.

E'LEMI. The resinous exudation of the *Amyris elemifera*, brought from the West Indies: it yields a volatile oil on distillation. It is used in ointments, giving them a gently stimulating character, and adding to their viscidity. The *compound elemi ointment* of the Pharmacopœia is a good preparation of this kind, and resembles the *yellow basilicon* of old pharmacy.

ELE'NCHUS. *See* SOPHISM.

ELEPHANTI'ASIS. A disease which chiefly affects the legs and feet, which become rough, scaly, and swollen, and have been compared to the feet of the elephant: the skin gets thick, unctuous, and insensible, and the limb occasionally attains an enormous size.

E'LEPHANT, WHITE. A Danish order of knighthood of great antiquity: the number of knights is limited to thirty, besides members of the royal family.

E'LEPHAS, or ELEPHANT. (Gr. ελεφας, *an elephant.*) The generic name of the most gigantic of existing quadrupeds. They are characterized essentially by having grinders composed of alternating vertical plates of ivory, enamel, and cæmentum, and two tusks in the upper jaw: they are also the only living Mammalia which have a proboscis or trunk longer than the head. It is inferred from the structure of the skull that the extinct Mastodons, which have grinders of a more simple structure, also possessed a long proboscis; and accordingly Cuvier includes the genus *Elephas* and *Mastodon* in a particular family of Pachyderms called *Proboscidians.* Of the true genus *Elephas* there are two living and a greater number of extinct species. The Indian elephant (*Elephas Indicus*, Cuv.) differs from the African species in its greater size, in the skull being higher in proportion to its length, and with a more concave forehead. The Indian elephant has also comparatively smaller ears; the skin is of a paler brown colour; and it has four nails on the hind feet instead of three. The elephant will breed in confinement; its period of gestation is twenty months and some days. It brings forth one young at a birth, which derives its nourishment from two nipples placed on the inner side of the setting in of the fore-legs. The perpendicular height of the Indian elephant, measured from the top of the shoulder, has not been found to exceed ten feet six inches: the ordinary height is from seven to nine feet. The Indian elephant varies as to the length of the tusks; their ends only are visible externally in the females, and there is also a race (Mooknah) in which they are straight and short in the males. In other races the males have the tusks long and curved, especially in that called "Dauntelah." The anecdotes of the docility, sagacity, and tenacious memory of the elephant are numerous and generally known. The characteristics of the African elephant may be inferred from the account of those of the Indian species. It is usual to describe it as having a forehead convex instead of concave; but the projection is caused by the nasal bones, which are higher placed than in the Indian species; and the true front is in reality concave in the African species, but in a less degree than in the Indian. The chief external character of the African elephant is his huge ears. It is a remarkable fact that no African nation has ever subdued the elephant, or made it available for any useful purpose. For an account of the fossil elephants, see MAMMOTH.

ELEUSI'NIAN MYSTERIES. The secret religious rites performed every year in honour of Ceres and Proserpine at the Attic town of Eleusis. To these mysteries all Greeks of both sexes, if unpolluted by crime, were admitted; and as persons thus initiated were considered to be peculiarly under the protection of the gods and to enjoy their favour, it was a privilege much sought after. It has been thought that many passages of ancient classical writers refer in a covert manner to these mysteries, and the doctrines disclosed in them: thus, the whole sixth book of the *Æneid* has been interpreted by Warburton and others as an allegorical exposition of them, a notion controverted by Gibbon in one of his early works. *See* MYSTERIES.

ELEVA'TION. (Lat. e, *from*, and levo, *I raise.*) In Architecture, a geometrical representation of a building measured vertically in respect of the horizon; by the an-

cient architects called the orthography. It is only in this sense that it is technically used by architects; in general terms it is the height of a building above the ground.

Elevation, in Astronomy, denotes the angular height or the altitude of a celestial object above the horizon. Thus, *elevation of the pole* denotes the arc of the meridian intercepted between the pole and the horizon.

Elevation, in Perspective, is sometimes used for the scenography or perspective representation of the whole object or building.

E'LEVATOR. A surgical instrument for raising depressed portions of the skull.

ELFS, or FAIRIES. Imaginary beings, honoured more particularly by the northern nations, in whose mythology they occupy a prominent place. They were divided into two classes — the good and the bad; and their exploits have given rise to a multiplicity of delightful stories. (See *Midsummer-Night's Dream:* and *Grimm's Deutsche Mythologie*, p. 259.) *See* Fairies.

E'LGIN MARBLES. A collection of ancient bas reliefs, statues, &c., which were chiefly decorations of the Parthenon at Athens, and are now deposited with some additions at the British Museum. Mr. Harrison, a northern architect of great abilities, suggested to Lord Elgin in 1797, at the period of his nomination to the embassy at Constantinople, the removal of these celebrated works. But it was not till some time after Lord Elgin's arrival that the ministers of the Porte were prevailed on to allow him to detach any portion of the marbles; and about eighty cases arrived in England in 1812. In 1816 the collection was purchased by government under a recommendation of a committee of the House of Commons at, if we rightly recollect, the sum of 35,000*l*. They are without question the finest productions of sculpture in the world.

EL'IMINA'TION. (Lat. elimino, *I put out.*) A term used by writers on algebra to denote that operation by which any number n of equations being given, containing n unknown quantities, a single equation is deduced from them containing only one unknown quantity; so that, by resolving this equation, we find the value of the unknown quantity it contains, and thence, by successive substitutions, the values of all the other unknown quantities. To eliminate a quantity is therefore to cause that quantity to disappear from an equation.

ELIQUA'TION. (Lat.) The separation of two metals by fusion.

ELI'SION. (Lat. elido.) In Grammar, the cutting off or suppressing of a vowel at the end of a word, for the sake of euphony or the measure of the verse. The use of the *elision* was confined chiefly to the languages of Greece and Rome.

ELI'XIR. (Arab.) A term applied in old pharmacy to certain essences or tinctures: a mixture of an aromatic tincture with sulphuric acid was called *elixir of vitriol*. The alchemists applied the term *elixir* to various solutions employed in the art of transmutation.

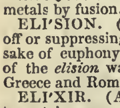
ELK. *See* Cervus.

ELLA'GIC ACID. An acid obtained by Braconnot from gall nuts, and differing from the gallic acid: the term is derived from the word *galle*, reversed.

ELLI'PSE. (Gr. ελλειψις, *defect.*) One of the conic sections, produced by cutting a cone by a plane passing obliquely through its opposite sides. (*See* Conic Sections.) The ancient Greek geometers gave this name to the figure, because, among its other properties, one is, that the squares of the ordinates are less than the rectangles under the respective abscissa and the parameter, or differ from them in *defect*.

Though the ellipse was first suggested to geometers from considering the sections of the cone, it may be defined in various ways, and all its properties investigated without any reference to the solid. We subjoin some of these definitions, which are, in fact, so many different properties of the ellipse.

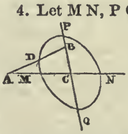
1. If two points F and f be given in a plane, and a point D be conceived to move around them in such a manner that the sum of the two distances D F and D f is always the same, the point D will describe upon the plane an ellipse A D B. The points F and f are the *foci* of the ellipse; and the point C, which bisects the distance between the foci, is its centre. The line A a is the *major* or *transverse axis;* and B b, which passes through the centre, and is perpendicular to A a, is the *minor* or *conjugate* axis. From this definition it is obvious how the curve may be described mechanically. Having fixed two pins F and f in the plane, let the ends of a thread be fastened to the two pins; then, moving a style or pencil within the thread, so as to keep it always stretched, the point of the style will describe the ellipse.



2. Let F be a given point, and M N a straight line given in position; if another point D move on the same plane so that its distance D F from F shall have always to the perpendicular D E, or its distance from the given line M N, the constant ratio of two given lines X and Y, of which X is less than Y, the point D will describe an ellipse. The line M N is called the *directrix*, and its distance from the centre C is such that C G is a third proportional to C F and C A. It is obvious that F A is to A G in the given ratio of X to Y.

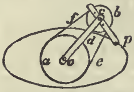
3. It is also a property of the ellipse that the rectangle under A H and H a is to the square of the ordinate H D in the ratio of the square of C A to the square of C B. From this property the common algebraic equation of the ellipse is derived. Let C A $= a$, C B $= b$, C H $= x$, and H D $= y$; then A H·H a : H D^2 : : $a^2 : b^2$, that is, $(a - x)(a + x) : y^2 : : a^2 : b^2$, or $a^2 - x^2 : y^2 : : a^2 : b^2$, whence $y^2 = \frac{b^2}{a^2}(a^2 - x^2)$. This equation may be put under the following elegant form, $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$.

4. Let M N, P Q be two straight lines intersecting each other in C; then if a straight line B A of a given length be carried along the two straight lines M N, P Q, any point D in A B (or in A B produced) will describe an ellipse the centre of which is at C. It is on this principle that elliptic compasses and lathes for turning ovals are constructed.



5. If a moving or generating circle roll along the concave circumference of a fixed circle in the same plane, and the radius of the former be half that of the latter, any given point in the plane of the generating circle, within or without it, will describe an ellipse. This very remarkable property of the ellipse, by which the curve is shown to be an epicycloid, was applied by Professor Wallace of Edinburgh to the invention of an ingenious instrument for describing an ellipse by continued motion. The construction of the instrument is as follows:—

"a and b are two wheels, the axes of which turn in holes c o, near the ends of the connecting bar d. One of the wheels b must be just half the diameter of the other a, which may be of any size, and a band e f goes round them outside; an arm c p is attached to the wheel b, and admits of being lengthened or shortened by sliding along its surface in a socket which may be any where on the wheel. Suppose now that the wheel a is fixed or kept from turning, and that the bar d is turned round the centre o, carrying at its other extremity the wheel b; the action of the band e f will then turn this wheel round its centre c; and while the bar makes one revolution round the centre of the fixed wheel, the other wheel will make two revolutions about its centre, and the point p in the sliding bar will describe the ellipse." (*Wallace's Conic Sections.*)



6. The ellipse is the curve in which the planets perform their revolutions about the sun, and its properties enter into almost every investigation connected with physical astronomy. In these investigations it is found most convenient to define the curve by means of an equation between the *radius vector*, that is, a line drawn from the focus to the curve, and the angle which it makes with the transverse axis. This is called the *polar equation* to the ellipse, and is found as follows:— Let F D the radius vector (see the first diagram) $= r$, C A $= a$, C F the eccentricity $= e$, and the angle A F D, which is called the *anomaly* $= \phi$; then $r = \frac{a^2 - e^2}{a + e\cos.\phi}$.

It is a property of the ellipse, that if a circle be described upon either axis, and from any point of that axis an ordinate be drawn both to the circle and ellipse, then the ordinate of the circle is to the ordinate of the ellipse as that axis to the other axis. Hence the whole area of the circle is to the whole area of the ellipse in the same proportion, and consequently the area of an ellipse is a mean proportional between the areas of the two circles described upon its transverse and conjugate axes. Hence, to find the area of an ellipse, multiply the two axes together, and multiply the product by ·7854. *See* Circle.

The whole length of the periphery of an ellipse is expressed by the following series:

$$2\pi\left(\overline{1} - \frac{1}{2^2}e^2 - \frac{1^2 \cdot 3}{2^2 \cdot 4^2}e^4 - \frac{1^2 \quad 3^2 \cdot 5}{2^2 \cdot 4^2 \cdot 6^2}e^6 - \frac{1^2 \cdot 3^2 \cdot 5^2 \cdot 7}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2}e^8, \&c.\right)$$

where 2π denotes the circumference of the circle described about the greater axis, and e is the eccentricit that is, $e^2 = 1 - b^2$, b being the semi-axis minor, and the semi-axis major being unit.

ELLI'PSIS. (Gr. ἐλλείπω, *I omit.*) In Grammar and Rhetoric, the omission of a word or part of a sentence, which is left to be supplied by the imagination of the hearer or reader.

ELLIPSOID. (Gr. ελλειψις, and ειδος, *form.*) A geometrical solid, of such a nature that every section of it made by a plane produces an ellipse.

ELLIPSOID OF REVOLUTION, called also the *Spheroid*, is the solid generated by the revolution of an ellipse about its lesser axis.

ELLIPTIC COMPASSES. An instrument for describing an ellipse by continued motion. An instrument of this kind has been described under ELLIPSE. Various contrivances for effecting this purpose are described in the *Exercitationes Mathematicæ* of Schooten.

ELLIPTI'CITY of the TERRESTRIAL SPHEROID. A term used by Clairaut and other writers on the figure of the earth, to denote the deviation of the earth's form from that of a sphere. Clairaut employed the term to denote the difference of the two axes divided by the smaller: most other writers understand by it the difference of the axes divided by the greater. Thus, let $a =$ the equatorial diameter, b the polar diameter, $e =$ the ellipticity; then $e = \frac{a-b}{a}$, whence $b = a\ (1-e)$.

ELM. A valuable genus of trees, confined to the colder parts of the northern hemisphere, but common to both the old and new world. Most of the species are trees of considerable size, and produce a timber useful for many common purposes in which great strength and durability are not required; but some of them are small bushes of no known value. In Great Britain there are several species in a wild state, the most valuable of which are called the Welsh, the Hertfordshire, the Huntingdon, and the smooth-leaved; in other countries of Europe and Asia many peculiar species exist, but they have been little examined by botanists. The elm is valued for the rapidity of its growth, its hardiness, and its capability of thriving in poor soil unfit for tillage. The word seems to be an alteration of ulmus, its Latin name.

ELOCU'TION (Lat. eloquor, *I speak out*), signified originally, as the derivation of the word imports, the art of choosing and adapting words and sentences to the ideas to be expressed; but it is more frequently employed to denote the just and graceful management of the voice, countenance, and gesture in speaking; in which sense it is synonymous with what is termed a *good delivery* or *pronunciation*. *See* DECLAMATION, ELOQUENCE.

E'LOGE. (Gr. ευλογια, Ang. *eulogy*.) A term applied in France to the panegyrical orations pronounced in honour of illustrious deceased persons, and particularly of members of the Royal and other academies. Formerly the secretaries of the various French literary institutions used to compose and pronounce the *éloge*; but this duty is now performed by the new member elected in the room of the deceased. This practice is no doubt open to censure; but it has been the means of giving to the world many interesting biographical sketches, which would never otherwise have appeared. *Eloge* is also applied to any species of biographical writing in which praise predominates over censure, and has been much cultivated by French and Italian authors.

ELONGA'TION, in Astronomy, is the apparent distance of a planet from the sun. The greatest elongation of Mercury amounts to about $28\frac{1}{2}$ degrees, and that of Venus to about 47° 48′. With regard to the superior planets, the elongation may have any value from 0 to 180°.

E'LOQUENCE. (Lat.) The art of clothing the thoughts in the most suitable expressions, in order to produce conviction or persuasion. In its primary signification, eloquence (as indeed its etymology implies) had reference to public speaking alone; but as most of the rules for public speaking are applicable equally to writing, an extension of the term naturally took place; and we find even Aristotle (*Rhe.* book iii.), the earliest systematic writer on the subject whose works have come down to us, including in his treatise rules for such compositions as were not intended for public recitation. A still wider extension of the term was contended for by the ancient rhetoricians, who included under it all kinds of literary productions (such as treatises on law, logic, &c.), and whatever might be necessary to illustrate and explain them. In the following observations, we shall confine ourselves chiefly to the etymological meaning of the word, and shall give a brief sketch of the history, the objects, and the divisions of eloquence. The invention of eloquence is ascribed by the Egyptians and the fables of the poets to the god Mercury; but no certain account can be given when or by whom this art first began to be cultivated. If we may judge from the eulogiums which Homer pronounced upon Ulysses and Nestor for their attainments in eloquence, it must have been very early in high esteem among the Greeks. But though, from time to time, there arose in Greece many distinguished writers upon eloquence, it does not appear that the practice of the art was combined with the theory for public purposes till the time of Pisistratus, who owed to his rhetorical acquirements his elevation to the throne. Passing from Pericles (the next in order to Pisistratus), who was distinguished at once as a general, a statesman, and an orator, we find many eminent names during the Peloponnesian war immortalized for their eloquence by the pen of Thucydides. In the succeeding age arose the school of rhetoricians, or sophists, as they are called, who endeavoured to graft upon eloquence the subtleties of logic; and among the earliest and most eminent of this school were Gorgias, Isocrates, and Isæus, of whose publicly delivered orations there are still ten extant. It was in this age that Grecian eloquence attained its highest perfection by the genius of Demosthenes, to whom the palm has been conceded by the unanimous consent of ancient and modern times. Various are the writers that have endeavoured to point out the beauties of Demosthenes; but by none are the peculiar qualities and distinguished properties of his style more vigorously and happily (though briefly) pourtrayed than by Hume, who, throwing aside his usual calm and dispassionate manner, thus describes it:—"It is rapid harmony exactly adjusted to the sense: it is vehement reasoning without any appearance of art: it is disdain, anger, boldness, freedom, involved in a continued stream of argument; and of all human productions, the orations of Demosthenes present to us the models which approach the nearest to perfection." After this period, Grecian eloquence declined rapidly; and though in the following ages there flourished among others Hermagoras, Athenæus, Apollonius, Cæcilius, and Dionysius, their names have been almost without exception rescued from oblivion by a work, which may be regarded as the last expiring ray of Grecian eloquence — the incomparable treatise of Longinus on the Sublime.

In consequence of the all-absorbing spirit for military glory with which the ancient Romans were animated, it was long before they found leisure to appreciate the advantages of eloquence; and even so late as the year of the city 592, when, by the industry of some Greeks, the liberal arts began to flourish at Rome, the senate passed a decree banishing all rhetoricians from the country. But a few years afterwards, when Carneades, Critolaus, and Diogenes were sent as ambassadors from Athens to Rome, the Roman youth were so charmed with the eloquence of their harangues, that the study of oratory formed thenceforth a branch of a liberal education. Men of the highest rank were now seen teaching and learning respectively the art of eloquence; and such was the impetus given to this study, that it made the most rapid advances, and was at last crowned by the appearance of Cicero, to whom critics have concurred in assigning a rank inferior only to that of Demosthenes. That many illustrious orators existed at Rome prior to the age of Augustus, we learn from the work of Cicero, *De Claris Oratoribus*. In this treatise Cicero, in detailed notices and liberal eulogiums, has given immortality to the very men whose works were thrown into obscurity by the splendour of his own: as Quintilian says of Menander and *his* predecessors — atque ille quidem omnibus ejusdem operis auctoribus abstulit nomen, et fulgore quodam suæ claritatis tenebras obduxit. The mighty scale on which every thing was conducted at Rome, and the enormous interests so frequently at stake, were never so wonderfully exhibited as in the age of Cicero; and the unparalleled exigency found or created in him a talent for profiting by its advantages or coping with its difficulties. In the succeeding ages of the Roman empire, the despotic character of the government checked the growth of the rhetorical art; but the names of Tacitus, Quintilian, and Pliny are an earnest of what might have been achieved in this arena, had circumstances permitted the development of their talents.

During the middle ages, though the practice of eloquence may, as far as we know, be said to have lain dormant, the theory formed part of the scholastic study, as may be seen from the old doggrel hexameter, which served to fix the monastic studies in the memory—

"Gramm. (Grammatice) loquitur; Dia. (Dialectice) vera docet;
Rhet. (Rhetorice) verba colorat."

With regard to the early history of eloquence in England, there are found, indeed, the names of several distinguished men who in former times directed the resolutions of our parliament; but no pains were taken to preserve their speeches; and, as Hume observes, the authority which they possessed seems to have been owing to their experience, wisdom, or power, more than to their talents for oratory. It was not until the close of the last century (a period which, it may be said, Hume did not live to see), that an era arose in the history of British eloquence, which the genius of Chatham, Pitt, Burke, Fox, and Sheridan has consecrated and immortalized.

We can only allude to the history of eloquence in other countries. The little opportunity afforded for a display of forensic or senatorial eloquence by the different governments of Germany has almost entirely checked its growth in that country; and the same remark is applicable to Italy, Spain, and Portugal; all of which, however, have been rich in the eloquence of the pulpit. The only two countries in the world whose orators can be put in competition with those of Britain, are France and America. To the pulpit oratory of the former, the illustrious names of Bossuet, Bourdaloue, and Massillon have given enduring celebrity; while the popular character of their respective institutions, has formed a host of forensic and senatorial speakers worthy a prominent place among the orators of antiquity, and modern times. The pulpit orators of England are too well known to be noticed here.

The elements of eloquence are usually comprised under the four following divisions — *invention*, *disposition*, *elocution*, and *delivery*. The first has reference to the character of the thoughts or ideas to be employed; the second to their arrangement (usually called the *parts* of a discourse, — consisting of the *exordium* or *introduction*, the *narration*, the *proposition* the *proof* or *refutation*, and the *peroration:* see these terms); and the third and fourth have respect to words, style, utterance, action, &c.

The Greeks divided discourses according to their contents, as relating to precept (λογους), manners (ηθη), and feelings (παθη), and as therefore calculated to instruct, to please, and to move. The Romans distinguished three kinds of eloquence: — the demonstrative, occupied with praise or blame, and addressed to the judgment; the deliberative, which acts upon the will by persuasion or dissuasion; and the judicial or forensic, which was used in defending or attacking — a division originally laid down by Aristotle, *De Rhetorica*. In our own times, a division somewhat similar has been made; and the bar, the senate, and the pulpit are the three grand theatres for the exhibition of oratory. With regard to the distinguishing characteristics of these three kinds of eloquence, the reader will find ample information on this head by consulting Blair, or *Campbell's Philosophy of Rhetoric*. The following is a summary of their views. In popular assemblies, the great object to be effected by the orator is persuasion: the speaker aims at determining his audience to adopt some line of conduct, as good, fit, or useful; and in order to accomplish this object, he must address himself to all the principles of action in human nature, — to the passions, to the heart, as well as to the understanding. At the bar, on the other hand, it is not persuasion, but conviction, that the orator aims at producing. There it is not the speaker's business to persuade the judges to what is good and useful, but to show them what is just and true. Hence it is chiefly to the understanding that his eloquence is to be addressed. Hence, also, the eloquence of the bar is considered by most rhetoricians of a more limited kind than that of popular assemblies. In many instances, however, the eloquence of the bar has a much wider scope than such writers have conceded, and the trial by jury admits of the most impassioned appeals to be found in the annals of modern eloquence. With regard to the eloquence of the pulpit, though it appears at first view to be possessed of many qualities advantageous to oratorical display, such as the dignity and sublimity of the subject, the large and mixed audience, and the leisure of the speaker for premeditation, these will be found to be counterbalanced by many disadvantages; *e.g.* the triteness of the subject, and the difficulty experienced by the speaker to excite attention. Besides, at the bar, or in the senate, the orator addresses passions which are forbidden ground to the preacher; and if at any time the latter makes an incursion into those regions, he is in danger of assuming a tone inconsistent with the dignity and the charity of his profession. The fierce invective, the terrible crimination, the bold and unexpected retort, the cutting sarcasm, the cool and dignified irony, on the one hand, — and, on the other, the skilful flattery, the exquisite artifice, with which the baser as well as the nobler passions of the audience are wrought into a subservience of the purpose of the orator; all these fall more or less within the province of the bar and the senate, but are beyond the sphere of the pulpit orator. With all these restrictions, however, the subject to which pulpit eloquence may be addressed are sufficiently extensive to admit of great oratorical display; and as to convince the intellect and force the unwilling homage of the reason, as well as to awaken the conscience and to arouse the imagination, are the objects of preaching, the pulpit orator may, by the choice of his subject, at one time be argumentative and ratiocinative at another declamatory and impassioned.

It is admitted on all sides that, in modern times, eloquence has not been invested with so much importance, or cultivated with so much care as among the ancients. For the cause of this alleged inferiority of modern as compared with ancient eloquence no satisfactory reason has been hitherto assigned, and even Hume has confessed his inability to solve the problem. Perhaps one cause of the ascendency of the ancient orators lies in the difference of the means employed in ancient and modern times to gain the consent of the audience. Among the ancients, the most violent and passionate expressions, accompanied by what Cicero calls the "supplosio pedis," and the "percussio frontis vel femoris," were not only admissible, but were even necessary, in order to produce an effect upon the audience. Among the moderns, such violence of gesture, except on the stage, would excite nothing but laughter. Those orators are now-a-days more esteemed who aim at convincing the understanding than at captivating the feelings; and this is a characteristic that pervades every species of modern eloquence. Again, if we look to the peculiarities of ancient law, the tribunals of justice, and the legislative assemblies of the Greeks and Romans, we may perceive, perhaps, the superior arena of the ancients. The great scope for eloquence in ancient times, as has been observed by an able writer in the *Quarterly Review*, arose from a circumstance that with us would be considered a vice — the blending of the legislative with the judicial powers. When the legislature is employed, as in England, in establishing, from the contemplation of a whole class of cases, a general principle for deciding on every future case that may be referable to that class; and when the judicial power is only occupied in ascertaining to what previously established legal class any particular case belongs, and what the decision of the law is regarding that class: in this state of things, there is scope, indeed, for the exercise of the most useful and respectable powers of eloquence, — the clear, strong, and elegant development of ratiocination, and of the information and the views of a comprehensive mind; and this is all. But when, as was the case in Greece and Rome, the written laws are few and vaguely expressed; when the judges exercise an undefined equitable jurisdiction, in the application of which they are not bound by any regulation of their predecessors; still more, when the tribunal is invested with a direct legislative power, the question is no longer to be decided by argument and the application to general principles alone, but the individual passions and interests of the judges are let loose; and then all the higher and more perilous faculties of the orator are called forth to rule in this war of elements, and direct the storm as may suit his purpose, — whether to sweep away falsehood and oppression, or to bear down the barriers of truth, law, and justice. (See *Whately's Rhetoric; Campbell's Rhetoric; Cicero, De Oratore;* and the works already mentioned.)

ELUTRIA'TION. (Lat. elutrio, *I cleanse*.) The separation of substances by washing them in large quantities of water, so that the heavier particles fall to the bottom, and the lighter ones, remaining some time suspended, are gradually deposited in a finely divided state.

ELYDO'RIC PAINTING. (Gr. ἔλαιον, *oil*, and ὕδωρ, *water*.) In Painting, a species of painting with a vehicle composed of oil and water, invented by M. Vincent of Montpetit. Its object is to add the fresh appearance of water colours and the extreme finish of miniature painting to the mellowness of oil colours. Not, however, having seen any specimen of it, we are unable to state from our own knowledge whether those objects have been attained.

ELY'SIUM, or the ELYSIAN FIELDS. (Gr. ηλύσια πέδια.) In Mythology, the region to which the souls of the virtuous were said by the poets to be transported after death. They are variously represented as a part of the infernal realms, or islands situated in the Western Ocean beyond the Columns of Hercules. The enjoyments of the blessed spirits in this abode were held to consist in the same pursuits that were their delight on earth, carried on in a calmer and happier climate: beautifully described in the well-known passage (*Odyss.* iv. 563.) —

Αλλα σ' ες ηλυσιον πεδιον και πειρατα γαιης, &c.

Thus admirably rendered by the late A. Moore: —

> Thee to the Elysian plains, earth's farthest end,
> Where Rhadamanthus dwells, the gods shall send:
> There mortals easiest pass the careless hour;
> There neither winter comes, nor snow, nor shower;
> But ocean ever, to refresh mankind,
> Breathes the shrill spirit of the western wind.

A tract on the coast of Campania was also termed the *Elysian Fields*.

E'LYTRUM. (Gr. ελυτρον, *a sheath*.) The superior or first pair of wings in four-winged insects are so called when they are of a coriaceous and hardly flexible texture, and serve as a protective covering to the second pair; as in beetles.

EMANATION, SYSTEM OF. In Philosophy. *See* PANTHEISM.

EMA'NCIPA'TION. (Lat., from mancupo, *I sell*, or deliver over the tangible property in any thing.) By the ancient Roman law, the son stood in the relation of a slave to the father. By a fiction of that law, the son might be freed from this relation by being three times sold (mancipatus) by the father. Hence the enfranchisement of the son derived from this ceremony the name of emancipation. In course of time, various modes of emancipation, both tacit and express, became recognized by the Roman jurisprudence. The word, in countries following that law, signifies the exemption of the son from the power of the father, either by express act, or by implication of law. By the present civil law of France, majority (and with it emancipation) is attained at 21 years of age; and the marriage of a minor emancipates him. (See *Code Civil*, lib. 1. ch. 3.) In ordinary language, emancipation is used in a general sense to signify the enfranchisement of a slave, or the admission of particular classes to the enjoyment of civil rights.

EMA'RGINATE. In Zoology, when the margin of a part is broken by an obtuse notch, or the segment of a circle.

EMARGI'NULA. A subgenus of Gastropodous Mollusks, dismembered from the genus *Patella* of Linnæus, and characterized by a shell of a simple conical form, but

having a narrow fissure extending from the margin to near the summit.

EMBA'LMING. (Lat. balsamum, *balm.*) A process adopted by the ancient Egyptians, chiefly for the preservation of dead bodies from putrefaction. The term is derived from the use of balsamic substances in the operation; in addition to these, saline substances and tanning materials seem also to have been used. *See* MUMMY. (See *Granville*, in *Phil. Trans.*; and *Pettigrew upon Mummies.*)

EMBA'NKMENT. In territorial improvement, an embankment is a mound of earth or a wall, or a structure composed partly of a wall and partly of a bank of earth, to protect lands from being overflown by rivers or the sea. Embankments appear to have been coeval with the culture of corn crops; because these, it appears, were first grown on the alluvial soils which border large rivers, and to protect the crops from the overflowing of these rivers after heavy or long-continued rains, the cultivator would naturally throw up a bank of earth. This appears to have been done in Egypt at the most remote period of which there is any record. In modern times, embankments are employed, not merely to protect lands under cultivation, but to enclose land that is occasionally overflown by rivers or the sea, and render it fit for the purposes of husbandry. This has been done to a greater extent in Holland than in any other country. There are also immense embankments in Italy, particularly in Lombardy. In Britain, we have the embankments of the Thames near London, which have been in existence since the time of the Romans; many in Lincolnshire, formed during the time of Cromwell, and some of them many centuries before; and one of the most recent is that at Tre Madoc in Caernarvonshire, by which upwards of 4000 acres were recovered from spring tides, and in great part rendered fit for the plough. Embankments are attended with immense expense; but as the soil gained or protected is generally of the best quality, a judicious embankment is commonly considered as paying about the same rate of interest as a landed estate.

EMBA'RGO. A restraint or prohibition imposed by the public authorities of a country on merchant vessels or other ships, to prevent their leaving its ports. Embargoes are usually imposed only in time of war, or in apprehension of an invasion; in which cases the government employs the ships under embargo in armaments, expeditions, and transportation of troops, &c. When it is found necessary to stop the communication of intelligence between any two places, an embargo is laid upon all ships, both foreign and under the national flag.

E'MBASSY. *See* AMBASSADOR.

E'MBER DAYS, in the Romish calendar, are certain fasts appointed by Pope Calixtus for imploring the blessing of the Almighty on the fruits of the earth, and upon the ordinations performed in the church at these times. They occur four times a year, or once in each of the four seasons; being the Wednesday, Friday, and Saturday after the first Sunday in Lent, after the Feast of Pentecost or Whitsunday, after the festival of Holy Cross on the 14th of September, and after the festival of St. Lucia on the 13th of December. The weeks in which the ember days fall are called *ember weeks.* The word *embers* signifies ashes, which the primitive Christians strewed on their heads at these solemn fasts.

EMBERI'ZA. (Lat.) The name of a genus of Passerine birds, characterized by having the upper mandible narrower than the under one, with the edges turned inwards, and with a hard knob on the palate: the entire bill has the usual short strong conformation of the *Conirostral* tribe of Passerine birds. It is now the type of a family, subdivided into minor genera, under the name of *Emberizidæ* or Buntings.

EMBE'ZZLEMENT, in Law, is a felony, consisting of the same class of acts which would in any other case amount to larceny, when committed by one employed as a clerk or servant, and by virtue of his office, on the goods and chattels of his employer.

E'MBLEM. (Gr. εμβλημα; from εν and βαλλειν, *to throw in.*) Literally, *something inserted.* This term has various significations; but it is used most frequently in English to signify a figurative representation, which by the power of association suggests to the mind some idea not expressed to the senses. In Bibliography, books consisting of a series of plates, containing emblematic subjects, with explanations, generally in verse, in Latin or modern languages, are termed books of emblems. They were fashionable in the latter half of the sixteenth century. The best known is the *Emblemata Alciati*, by André Alciat, a French lawyer, which went through many editions.

EMBOLI'SMIC (Gr. εμβαλλω, *I insert*), in Chronology, signifies the same thing as *intercalary*, and is chiefly applied to the additional months required to fill up the lunar cycle. *See* CYCLE and EPACT.

EMBO'SSING, *Embossment.* (Fr. bosse, *a protuberance.*) In Architecture and Sculpture, the raising or forming in rilievo any sort of figure, whether performed with a chisel or otherwise. It is a kind of sculpture, in which the figures rise from the plane on which they are formed; and as they are more or less prominent, they are said to be in alto, mezzo, or basso rilievo.

EMBOUCHU'RE (Fr.), signifies the mouth of a river; it is used also for the mouth-piece of a musical instrument.

EMBRA'CERY. (Norm. Fr. embraserie.) In Law, the offence of endeavouring to corrupt or influence a jury; punishable by fine and imprisonment.

E'MBRASU'RE. In Fortification, an opening made in the wall or parapet of a fortified place, or breast-work of a battery, through which the guns are fired. The embrasures are usually made about two and a half feet wide at the interior extremity, and eight or nine feet at the exterior; and the sole or lower surface is at the height of about two and a half feet above the platform on which the carriage of the gun is placed; but their forms and dimensions are of course varied, according to their position relatively to that of the point against which the fire is to be directed.

E'MBROCATION. (Gr. εμβρεχω, *I moisten.*) A fluid application to any part of the body when painful or inflamed.

EMBROI'DERY. (Fr. broderie.) The name given to the art of working figures on stuffs or muslin with a needle and thread. All embroidery may be divided into two sorts, embroidery on *stuffs* and on *muslin*: the former is used chiefly in church vestments, housings, standards, articles of furniture, &c., and is executed with silk, cotton, wool, gold and silver threads, and sometimes ornamented with spangles, real or mock pearls, precious or imitation stones, &c.; the latter is employed mostly in articles of female apparel, as caps, collars, &c., and is performed only with cotton. In Germany this division is indicated by the expression *weisse* (*white* or muslin), and *bunte Stickerei* (*coloured* or cloth) *embroidery.* The embroidery of *stuffs* is performed on a kind of loom or frame; that of *muslin* by stretching it on a pattern already designed. The modes of embroidering stuffs or muslin with the common needle are extremely various; but a minute description of these processes would be as difficult as it would be uninteresting to the general reader. They consist for the most part of a combination of ordinary *stitches*; but no limit can be assigned to their number or variety. The art of embroidery was well known to the ancients. As early as the time of Moses we find it practised successfully by the Hebrews; and long before the Trojan war the women of Sidon had acquired celebrity for their skill in embroidery. At a later period, this art was introduced into Greece, probably by the Phrygians (by some considered as the inventors); and to such a degree of skill did the Grecian women attain in it, that their performances were said to rival the finest paintings. In our own times the art of embroidery has been cultivated with great success, more especially in Germany and France; and though for a long period it was practised only by the ladies of these countries as an elegant accomplishment, it is now regarded as a staple of traffic, and furnishes employment for a large portion of the population. In England also it appears to have taken deep root, as it now forms an accomplishment of which almost every lady is in possession. About seven years ago a great impetus was given to the cultivation of this art, both on the Continent and in England, by the invention of a machine which enables a female to execute the most complex patterns with 130 needles, all in motion at once, as accurately as she could formerly do with one. But as no account of this remarkable invention which we might give could be intelligible without the aid of illustrations, which would be out of place in this work, we must refer the reader to *Dr. Ure's Dictionary of Arts, &c.* for full information respecting it. One such machine with 130 needles is estimated to perform daily the work of 15 hand embroiderers employed in the ordinary way. Many of them are now mounted in Germany, France, and Switzerland; and in Manchester there is one factory where they do beautiful work. (See the *Art of Needle-work*, edited by the Countess of Wilton. Lond. 1840.)

E'MBRYO. (Gr. εμβρυον, from βρυω, *I bud forth.*) In Botany, a fleshy body occupying the interior of a seed, and constituting the rudiment of a future plant. It is divided into three parts;—viz. a plumula or growing point, a radicle or root, and a cotyledon or cotyledons. It is the vegetable fœtus; and is so tenacious of life under particular circumstances, that there are well-attested instances of its having preserved its vitality much beyond 1000 years. The term is also applied to the fœtus in utero before the fifth month of pregnancy, because its growth has been compared to the budding of a plant.

EMBRYO'TOMY. (Gr. εμβρυον, *the fœtus*, and τεμνω, *I cut.*) The operation of cutting the fœtus out of the womb.

E'MERALD. (Fr. emeraude.) A mineral of a beautiful green colour, which occurs in prismatic crystals, and is much valued for ornamental jewellery. The finest are obtained from Peru. It consists of 65 silica, 16 alumina, 13 glucina, about 3 oxide of chromium (which is the colouring matter), and a trace of lime. (*Vauquelin.*) The mines from which the ancients obtained emeralds are said to have existed in Egypt, near Mount Zabarah. (*Caillaud.*)

EME'RITI. (Lat.) The name given to the soldiers and other public functionaries of ancient Rome, who had retired from their country's service. On these occasions the parties were entitled to some remuneration, resembling our *half-pay;* but whether it was a grant of land or of money has not been accurately ascertained.

EME'RSION. (Lat. emergo, *I sink.*) In Astronomy, the reappearance of the sun, moon, or planets, or of a star, from behind the celestial body by which it has been eclipsed. The phenomena of *immersions* and emersions are of considerable use in determining the longitudes of places.

E'MERY. (From Cape *Emeri* in the island of Naxos.) A variety of corundum; amorphous, compact, and generally opaque. It is characterized by excessive hardness; and its powder is used for cutting and polishing glass, gems, and all hard substances: it scratches and wears down nearly all minerals except the diamond.

EME'TICS. (Gr. εμεω, *I vomit.*) Medicines which occasion vomiting. The only vegetable emetic in general use is *ipecacuanha*, from ten to twenty grains of which is a dose; the chief mineral emetics are the *tartrate of antimony and potash*, or *emetic tartar*, *sulphate of zinc*, and *sulphate of copper*. When it is merely wished to evacuate the contents of the stomach in cases where it is disordered by improper food, twenty grains of ipecacuanha in an ounce of water is a safe and good emetic; it generally operates in ten to twenty minutes, and its action may be assisted by chamomile tea or warm water. At the beginning of fevers or inflammatory disorders, an emetic is often advantageously administered, and then ten or fifteen grains of ipecacuanha with half a grain or a grain of emetic tartar in an ounce and a half of water is to be preferred: the perspiration which the vomit induces should be kept up by remaining in bed, and by warm drinks or other proper remedies. Where poisons have been swallowed, the stomach is often insensible to these means, especially where large doses of opium are concerned; and then half a drachm of sulphate of zinc or of sulphate of copper may be dissolved in three ounces of warm water, and a third part of the solution taken every ten minutes till it operates. In such cases, however, the stomach-pump is principally to be relied upon. When emetics are given in small doses, they produce *nausea*, and to this extent they have proved useful in restraining hæmorrhage of the lungs and stomach. Emetics should be avoided in all plethoric habits, and where there are any symptoms announcing fulness of the vessels of the head; in hernia, in the advanced stage of pregnancy, and in active inflammations. They should also be given with the utmost caution to young children; and when given, ipecacuanha should be resorted to. Old chronic pains and obstinate rheumatism are sometimes relieved by an emetic.

EME'TIC TA'RTAR. A triple salt, composed of oxide of antimony, potassa, and tartaric acid. It is soluble in eighteen parts of cold and in three of boiling water. In the dose of from half a grain to two grains it operates as a powerful emetic and sudorific; in smaller doses, it acts upon the bowels, and is diaphoretic.

E'METINE. A substance discovered in 1817 by Pelletier in ipecacuanha. It is white, pulverulent, and bitter; easily soluble in hot water and alcohol, and intensely emetic. It exists in ipecacuanha to the amount of about 16 *per cent.*, and appears to be the sole cause of its emetic property.

EMIGRA'TION. (Lat.) Migration is the movement of an individual or a number of people from one place of residence to another; emigration, their abandonment of their former home; immigration (a word of modern coinage), their settlement in their new one. Emigration is, in modern times, chiefly regarded in the light of a mode of relieving a country or district labouring under excess of population. The prejudices which formerly existed against it, on account of the loss of inhabitants thus sustained by a country, have long been removed, both by severe necessity, and by the progress of economical knowledge. The power of reproduction in the human race is so great, that the vacuum occasioned by any practicable amount of emigration is speedily filled. It was long ago observed that those provinces in Spain from which the most constant emigration to America was going on (Biscay, Asturias, &c.) were among the best peopled. The subject of emigration, considered in an economical light, has been amply discussed by Sir W. Horton (1825, &c.), by Col. Torrens, and by Mr. G. Wakefield (*on Colonization*, 1830, in which there are some curious calculations as to the effect produced on the movement of population by the emigration of a comparatively small number of marriageable persons: England and America, 1837). Emigration from our islands has for two centuries been chiefly directed to North America; of late years, the Cape of Good Hope and Australia have begun to absorb a small portion of our surplus population. In 1831, a government commission on emigration was formed, with a view to the regulation of the practice; by which officers were appointed both at home and in the North American colonies to watch over the interests of emigrants and furnish them with necessary information. With reference to Australia, they established, for the first time, the useful principle of disposing of the public lands by sale, in order to form a fund for emigration. The following table, showing the number of emigrants who have left the United Kingdom from 1825 to 1837 inclusive, is taken from the *Journal of the London Statistical Society*, i. 159.

1825 - 14,891	1830 - 56,907	1835 - 44,478
1826 - 20,900	1831 - 83,160	1836 - 75,417
1827 - 28,003	1832 - 103,140	1837 - 72,034
1828 - 26,092	1833 - 62,527	
1829 - 31,198	1834 - 76,222	In all - 694,969

Of these there went, in 1837,

29,884 to the North American colonies.
36,770 to the United States.
326 to the Cape of Good Hope.
5,054 to the Australian colonies.

The number in the same year from England was 40,502
—— Scotland - 4,779
—— Ireland - 26,753

The control of this important department is now (1841) transferred to three officers, entitled Commissioners of Colonial Lands and Emigration.

E'MINENCE. A title of honour borne in Europe by various dignitaries at different times; but appropriated to cardinals by a papal decree of the year 1630.

E'MIR. (In Arabic, *chief* or *lord.*) The khalifs took the title of *Emir-al-Mumenin*, — chief or commander of the Faithful. The title is now given by prescriptive usage to those who are considered to descend from Mohammed, by his son-in-law Ali and daughter Fatima (*see* SCHERIF, a title having the same application). But when joined to another word expressive of a particular command or office, it is a common title of dignity; as, *Emir-al-Omrah*, — a title given by the Turks to viziers and pachas, &c. *See* MIRZA.

EMME'NAGOGUE. (Gr. εμμηνιος, *monthly*, and αγω, *I move.*) Medicines which promote the menstrual evacuation.

EMO'LLIENTS. (Lat. emollio, *I soften.*) Medicines which are supposed to relax the living animal fibre.

E'MPEROR (Lat. imperator), was originally merely the title of a Roman general; but, on the fall of the republic, it was particularly applied to the head of the state. The authority of the Roman emperors was formed principally by the combination of the chief offices of the old republic in a single person; besides which, some extraordinary powers were conferred. Thus, Octavius held the titles of emperor, proconsul, and tribune, pontifex maximus or high priest; and was invested with perpetual consular authority, and also that of the censorship. Besides this, he was termed prince of the senate, and Augustus, which designation descended to his successors; but he was much more moderate in his use of titular dignities than his successors, contenting himself with substantial power. The provinces of the empire were divided between the senate and emperor, who appointed their governors, distinguished by the respective titles of proconsul and proprætor; but this division threw all the armies into the hands of the latter, as he took for his share the frontier provinces. The emperors appointed their own successors, who were dignified with the title of Cæsar, and in later times enjoyed a share in the government. Dioclesian first divided the care of the empire with a second Augustus in the person of Maximian, and each of these colleagues associated with himself a Cæsar. After the court was removed to Constantinople, the old titles and forms of the republic vanished by degrees, and the emperors assumed the style of oriental princes.

Charlemagne assumed the title of emperor after his coronation at Rome; and from his time this title (in German *kaiser*) was claimed exclusively, in western Europe, by the rulers of Germany. On the dissolution of the German empire in 1805, the title passed to the emperor of Austria, and, in the same year, Napoleon assumed it in France: the czars of Russia claimed it in the reign of Alexander.

E'MPHASIS. (From the Greek preposition εν, and φημι, *I speak.*) In Elocution, the stress laid on particular words or syllables in the pronunciation of a sentence, in order to express or enforce a meaning. It is divided by some writers into emphasis of force, which we lay on almost every significant word; and emphasis of sense, which we lay on particular words, to distinguish them from the rest of the sentence.

EMPHYSE'MA. (Gr. εμφυσαω, *I inflate.*) A collection of air in the cellular membrane, rendering the part tense and elastic, and crepitating when pressed.

EMPHYTE'USIS. (Gr. εμφυτευσις, from φυτον, *a plant;* a contract conveying the right of cultivation.) In the Civil Law, a contract by which houses or lands are given to be possessed for ever, or for a long term, on condition they shall be improved, and a small annual rent or pension (*canon emphyteuticus*), either in money, grain, or

any other thing, reserved and made payable to the grantor as a recognition of his paramount title. The grantor is said to retain the *dominium directum*, the grantee to acquire the *dominium utile*. The Scottish grant in feu-farm resembles the emphyteusis. From this word (pronounced in the lower age of Latinity emphytefsis) it is supposed that fief (fevodum, feodum) is derived.

E'MPIRE. (Lat. imperium.) Originally the territory or extent of land under the command and jurisdiction of an emperor. The dominions under the sway of ancient Rome were the first to which the term empire was applied: they consisted of two grand divisions,—the Empire of the East, or, as it was afterwards called, the Lower Empire; and the Empire of the West. The former admitted of various subdivisions in reference to the different dynasties to which it was subject; and the latter became, about the end of the 9th century, the German or Holy Roman Empire. In all these cases the sovereign or chief person in the empire was named the emperor. But the term empire has in several instances been employed to designate *a large extent of dominion*, without reference to the title of the ruler or sovereign of a country: thus we hear of the empire of Persia, Hindostan, &c. The dominions of the Queen of England are invariably designated the British Empire; and the epithet "imperial" is officially prefixed to the parliament of the United Kingdom. The term empire was applied from 1804 to 1814 to the dominions of France, including all the countries then incorporated with it by the conquests of Napoleon.

EMPI'RIC. (Gr. εμπειρικος.) One whose knowledge is founded on experience. The empiric school of medicine was opposed to the *dogmatic*; it appears to have originated with Serapion of Alexandria. The empirics considered the foundation of medical science to rest upon experience, derived either directly from experiment or from chance and imitation. They were, however, a pretending, and generally ignorant sect; so that the term empiric is generally applied to quacks and pretenders, without reference to its strict etymology, which should have limited it to the study of medicine, in accordance with the principles of Lord Bacon's philosophy.

EMPLE'CTON. (Gr. εμπλεκω, *I entangle*.) In Architecture, a method of constructing walls, in which, according to Vitruvius, the front stones were wrought fair, and the interior left rough and filled in with stones of various sizes.

EMPO'RIUM. (Gr. εμποριον.) A Greek word wholly naturalized in England, signifying a city or place where great commercial transactions are made. This word has been in use in England upwards of three centuries.

EMPROSTHO'TONOS. (Gr. εμπροσθεν, *forwards*, and τεινω, *I draw*.) A spasmodic action of the muscles, by which the body is involuntarily drawn forwards.

EMPYE'MA. (Gr. εν, *in*, and πυον, *pus*.) A collection of purulent matter in the cavity of the thorax. This is an occasional termination of pleurisy, and is attended by difficulty of breathing and inability to lie on the side opposite that which is affected; an external swelling is sometimes perceptible, and the matter has occasionally been let out by making an opening between the sixth and seventh ribs.

EMPYRE'AL AIR. Oxygen gas.

EMPYREU'MA. (Gr. εμπυρευω, *I kindle*.) A burned odour. Hence, the oils obtained by distilling various organic substances at high temperatures are called *empyreumatic oils*.

EMU. A three-toed Struthious bird, peculiar to Australia, differing from the *rhea* of South America in the extreme shortness of its wings, and from the cassowary of Java in the absence of the horny projection on the head.

EMU'LGENT. The artery and vein of the kidney are so called.

EMU'LSION. (Lat. emulgeo, *I milk*.) A milky liquid; as *almond emulsion*.

EMU'NCTORIES. (Lat. emungo, *I drain off*.) The excretory ducts of the body.

E'MYDINES, *Emydina*. A section of Chelonian reptiles or tortoises, having the genus *Emys* as the type.

EMY'DO-SAURIANTS, *Emydo-sauria*. (Gr. εμυς, and σαυρος, *a lizard*.) The name of an order of the class *Reptilia*, including the tribe of Crocodiles (*Crocodiliens*, Cuv.), which form part of the order *Sauria* of the *Règne Animal*.

ENA'LIOSAU'RIA. (Gr. εν, *in*, ἁλς, *the sea*, and σαυρος, *a lizard*.) A name applied to the entire group of extinct Saurians, in the organization of which paddles, like those of the whale or turtle, were combined with the head and trunk of a crocodile. *See* Ichthyosaur, Plesiosaur.

ENA'MEL. (Fr. enemail.) A semitransparent or opaque glass. Common glass fused with oxide of tin is converted into enamel. It is often variously coloured.

ENAMEL OF TEETH. *See* Teeth.

ENAMEL PAINTING. (Fr. en email.) In Painting, the art of painting with vitrifiable colours on thin plates of metals which are melted on to it. This art is of extremely high antiquity; it was practised by the Egyptians to a considerable extent, and by the Etruscans from the time of Persenna. After lying dormant, or at least in little vogue, for centuries, it was renewed in Italy under the pontificate of Julius II. The various colours used are prepared from oxides of different metals, melted with some vitrescent mixture laid on with a fine brush, the medium being oil of spike or some other essential oil; and it is not difficult to conceive, says Mr. Aikin, "how much the difficulties of this nice art are increased, where the object is not merely to lay a uniform coloured glazing on a metallic surface, but also to paint that surface with figures and other designs that require extreme delicacy of outline, accuracy of shadowing, and selection of colouring. The enamel painter has to work, not with actual colours, but with mixtures which he knows from experience will produce certain colours after the operation of the fire." This work requires several firings. The outline is first burnt in, after which the parts are filled up gradually with repeated burnings to the last finishing touches.

ENARTHRO'SIS. (Gr. εν, *in*, and αρθρον, *a joint*.) The ball and socket joint.

ENCA'MPMENT, in Military affairs, signifies the position occupied for an indefinite period by an army, with all its artillery, stores, baggage, &c., either for the purposes of exercise or warfare.

ENCANTHIS. (Gr. εν, *in*, and κανθος, *the angle of the eye*.) A small tumour or excrescence growing from the inner angle of the eye.

ENCA'RPUS. (Gr. εν, and καρπος, *fruit*.) In Architecture, the festoons on a frieze, consisting of fruits, flowers, leaves, &c.

ENCAU'STIC PAINTING. (Gr. εν, and καυστικος, *burning*.) In Painting, a method of painting used by the ancients, the precise mode of executing which is by no means sufficiently explained. From Pliny's account, it seems that the colours were made up into crayons through a medium of wax, and, the subject being previously traced with a metal point, were melted on the picture as they were used. The picture being finished, a varnish of melted wax was spread over all. The colours thus not only obtained considerable brilliancy, but the work was also protected from the weather. It was lastly well polished. The attempts to revive this art, which, after all, if we may draw our conclusion from Pliny's account, seems to have been but a clumsy process, have not been attended with success.

ENCE'PHALOCE'LE. (Gr. εγκεφαλος, *the brain*, and κηλη, *a tumour*.) Hernia of the brain. There are two kinds of this disease: one occurs in young infants, before the skull is completely ossified; the other presents itself after the destruction of a part of the skull in consequence of disease, accident, or the operation of the trepan.

ENCE'PHALON. (Gr. εν, *in*, and κεφαλη, *the head*.) The brain. The contents of the cranium.

ENCHA'NTMENT. The name given to the charms or ceremonies to which magicians have recourse in the practice of their art. It is derived from the Lat. in, and cantare, *to sing*; and is so called because the formulæ used in magic were usually written in verse and designed to be sung. *See* Magic, Demonology.

ENCHASING. *See* Chasing.

ENCHIRI'DION. (Gr. εγχειριδιον, from ἐν, *in*, and χειρ, *the hand*.) In Literature, a brief and useful compilation; a *manual*. The ethical treatise of Epictetus is termed his *Enchiridion*.

ENCLI'TICS. *See* Particles.

E'NCRINITES. *See* Crinoideans.

ENCYCLOPÆ'DIA. *See* Cyclopædia, Dictionary.

ENCY'STED. A term applied to tumours which are inclosed in a sac or cyst.

ENDE'CAGON, or UNDECAGON. (Gr. ενδεκα, *eleven*, and γωνια, *angle*.) A plane geometrical figure bounded by eleven sides. If the sides are all equal, and the length of each be supposed = 1, the area of the figure is 9·36564.

ENDE'MIC. (Gr. εν, *amongst*, and δημος, *the people*.) A disease peculiar to a certain class of persons, or to a certain district. Thus agues or intermittent fevers are endemic in low countries,—the *goitre* in the Alps, the *plica Polonica* in Poland. *See* Epidemic.

E'NDOCA'RPIUM. (Gr. ενδον, *within*, and καρπος, *fruit*.) A term invented by Richard to denote the inner coat or shell of a fruit.

E'NDOGENS. (Gr. ενδον, and γεινομαι, *I grow*.) One of the primary classes of plants, so called because their stems grow by successive additions to the inside. They are usually known by the veins of their leaves running parallel with each other, without branching or dividing. Grasses, lilies, the asparagus, and similar plants belong to this class, which in warm countries contains trees of large size, such as palms and screw pines.

ENDOPHY'LLOUS. (Gr. ενδον, and φυλλον, *a leaf*.) A term invented by Dumortier to denote the young leaves of Monocotyledons, from their being évolved within a sheath, while those of Exogens are not so enclosed.

ENDOPLEU'RA. (Gr. ενδον, and πλευρα, *the side*.) In Botany, the internal integument of a seed.

E'NDORHI'ZÆ. (Gr. ενδον, and ῥιζα, *a root.*) A term invented by Richard for the embryo of Monocotyledons, in which the radicle has to rupture the integument at the base of a seed prior to entering into the earth, appearing as if it came from within the mother root.

ENDORSEMENT. *See* EXCHANGE.

E'NDOSI'PHONITES. (Gr. ενδον, *internal;* σιφων, *a tube.*) A genus of extinct Cephalopods, with chambered convolute discoidal shells, having the siphon placed at the inner side of the turns, as in the Spirula. The *Endosiphonites* characterize the slate rocks of the Cambrian system, and have not yet been observed in the Silurian formation.

ENDOSMO'SE. (Gr. ενδον, and ωσμος, *impulsion.*) The transmission of gaseous bodies, or vapours or liquids, through membranes or porous substances from without inwards.

ENDOSPE'RMIUM. (Gr. ενδον, and σπερμα, *seed.*) A term invented by Richard to denote the albumen of seeds.

E'NDOSTOME. (Gr. ενδον, and στομα, *the mouth.*) The passage through the inner integument of a seed immediately below the part called the foramen.

ENDOTHE'CIUM. The fibrous cellular tissue lining an anther.

ENDOW'MENTS. *See* FOUNDATION.

ENEID. *See* ÆNEID.

ENE'MA. (Gr. ενιημι, *to inject.*) A medicine injected into the rectum. A clyster.

ENFEOFFMENT. *See* FEOFFMENT.

ENFILA'DE. A term used in military language to denote a fire of artillery or musketry in the direction of the enemy's line. A trench or parapet is said to be *enfiladed* when guns are so placed that the shot can be fired into it in a direction parallel to its length.

ENFRA'NCHISEMENT (Fr. franchise, *freedom or right*), in Law, is the act of incorporating a person into any society or body politic; as where one is made a citizen or free burgess of a town corporate. In feudal usage, a villein was said to be enfranchised when he was made free by his lord; and hence is derived the popular signification of the term. For enfranchisement of land, see COPYHOLD.

ENGA'GED COLUMNS. In Architecture, columns attached to walls, by which a portion of them is concealed; they never stand less than one half out from the walls.

ENGA'GEMENT, signifies either a battle by sea or land; but it is applied more frequently to the former, being synonymous with *action.* An engagement between two ships is called simply an *action:* between fleets a *general action.* As the object is to get possession of the enemy if possible, efforts are made either to disable him by cannonading, or, as is the practice of the English, to board him at once. The conquered vessel strikes (hauls down) her colours, which are afterwards replaced by those of the enemy hoisted over them.

E'NGINE, in Mechanics, is used to denote generally any kind of machine in which two or more of the simple mechanical powers are combined together.

ENGINE'ERING. (Fr. engine.) Strictly, the art of managing engines; but latterly applied in a more extended sense, not only to that art, but to all manufacturing and building operations in which engines are used. It is divided into two branches, Military and Civil.

Military engineering, as a science, implies a knowledge of the construction and maintenance of fortifications, and all buildings necessary in military posts; and hence includes a thorough instruction on every point relative to the attack and defence of places. The science also embraces the surveying of a country for the various operations of war, and consequently an acquaintance with mathematics and facility in drawing. When at a siege the engineer has surveyed a place, he reports to the commander the weakest places, and those in which approaches may be made with most success. He draws the lines of circumvallation and contravallation; marks out the trenches, places of arms, batteries, and lodgments; and in general directs the workmen in these operations. He should possess a practical and theoretical knowledge of gunnery. In regard to the marine branch of military engineering, it requires of course a general acquaintance with the construction of vessels, jetties, moles, and other buildings of that description.

Civil engineering, as its name imports, does not include those branches above named which specially belong to the art of war; but relates to the forming of roads and bridges, railroads, the construction of machinery for all purposes, the formation of canals, aqueducts, harbours, drainage of a country, &c. Till the year 1760, civil engineering was little cultivated in England as a distinct occupation; at that period, manufactures began to be extended by the enterprise, the capital, and science of a number of individuals eminent for their deep knowledge and persevering industry. New and more appropriate situations were chosen for carrying them on than the small towns in which they had been seated, and where combinations and corruption made the wages of the workman extravagant. Internal navigation was consequent upon this change: communication from harbours to warehouses, and the converse, as well as facility of transport from factory to factory, became absolutely necessary. Hence a system of canal navigation and aqueducts, which perhaps will not be entirely superseded even by the more modern railroad. Previous to the above period, a few jetties and piers of defence were thrown out in our seaports, affording to the mariner little better protection than nature herself: they have since become harbours of refuge; some of them are capable of holding large navies. The application of the steam engine to almost every purpose, independent of its importance in manufactures, has smoothed the difficulties formerly experienced in forming works under water, and has now made rapid strides towards superseding all animals of draught. To give the faintest outline of the science of practical engineering would be to write treatises on mathematics, mechanics, hydraulics, hydrostatics, and the other branches of natural philosophy: the reader must therefore seek for information under the separate heads of science involved in it.

ENGLAND, CHURCH OF. The period at which Christianity was first preached in this country has not been settled with any certainty; but there was certainly a British church existing in the island at the time of the mission of Augustine, in the year 597, to convert the Saxons. The British church, however, at that time, had shared the fate of the general British population, and had been pent up by the pressure of the heathen invaders within narrow limits at the extremities of the island. It can hardly be thought to have retained sufficient vigour to have effected the conversion of the barbarians, and would probably have died out but for the seasonable reinforcement from Rome. If such be the case, we must allow that Christianity in Britain owes at least its second foundation to the Romish see; but this foundation took place at a comparatively pure age, and possibly the influence of the uncontaminated religion of the Britons may have had its effect in preserving to the Saxons a very modified form of popery. Certain it is, as has been shown from existing homilies by Anglo-Saxon prelates, that some of the principal novelties of the Romanists were unknown to or repudiated by the English church, at least up to the time of Edward the Confessor.

The intercourse with France, which began to take place in that reign, and the superstitious temper of the monarch, prepared the way for the introduction of the Roman power: it was furthered by the necessities of the usurpers William and Stephen. Under Henry II. royalty took the alarm, and a fierce struggle took place, in which the papal authority was eventually victorious. Under John, the triumph of Romanism was completed, when the crown of England was actually given into the hands of Innocent III. But at that very time the seeds of the Reformation were being sown among the lowest classes: sects of strolling fanatics were constantly appearing and passing away; misguided themselves, but drawing the attention of the people to the errors of the church; and at length, under the impulse given by the learning of Wiclif, taking a definite and lasting shape under the name of the Lollards. A general reformation in opinion was almost at hand, when Henry VIII. threw off the supremacy of the Pope. But while he encouraged the reformers by that step, he checked them by severe enactments upon points of belief; and, as far as he is concerned, it may be doubted whether he at all assisted the development of the Reformation. The Church of England was first reformed by law on the accession of Edward VI.; but many points of doctrine and discipline were left untouched; and the enactments of Elizabeth, by which its whole constitution was finally settled, followed rather than preceded the expressed convictions of the nation. (For the variations that have since taken place in the services of the church, see art. COMMON PRAYER.) The government of the Church of England is episcopal, and the bishops sit in the House of Lords by virtue of the temporal baronies into which their benefices were converted by William the Conqueror. This constitution was subverted on the success of the Great Rebellion, and presbyterianism established in its stead; but the episcopal form was restored in 1660 with the return of Charles II.

ENGLISH ARCHITECTURE. We have already, under the article ARCHITECTURE, given a general view of the rise and progress of Gothic architecture. Our purpose in this place is to enter into details respecting its subdivisions in this country. Without disrespect to the later writers who have differently arranged and named the styles, we think none more convenient than that used by the Rev. Geo. Millers (in his description of the cathedral church of Ely) for giving the reader a succinct and satisfactory view of some of the examples which England affords. We propose, therefore, to subdivide the styles into five periods: — 1*st Period*, or *Anglo-Saxon*, which may be comprised from A. D. 600 to 1066, that is, from the conversion of the Saxons to the Norman Conquest; 2*d Period*, or *Norman*, from 1066 to nearly 1200, comprising the reigns of William I., William II., Henry I., Stephen, Henry II., and Richard I.; 3*d Period*, or *Early English*, from 1200 to 1300, or during the reigns of John, Henry III., and Edward I.; 4*th Period*, or *Ornamented English*, 1300

to 1460, comprising the latter portion of the reign of Edward I., that of Edward II., Edward III., Richard II., Henry IV., Henry V., and Henry VI.; *5th and last Period*, or *Florid English*, by some called the *Tudor Style*, from 1460 to the dissolution of the religious houses in 1537, comprising the reigns of Edwards IV. and V., Richard III., Henrys VII. and VIII.

Ducarel, in his *Norman Antiquities*, enumerates the churches in England anterior to the Norman Conquest; among which appear those of Stukely in Bucks, Barfreston in Kent, and Avington in Berks. Other examples are to be found in Waltham Abbey; the transept arches of Southwell, Notts; the nave of the abbey church of St. Alban, Herts; nave of St. Frideswide, Oxford, &c. The principal characteristics of this the *First Period* are,

(1)

arches (1) of semicircular form, frequently quite plain, occasionally decorated with various sorts of mouldings, both on the face and soffit; often double, triple, or quadruple, each projecting beyond the face of the other, with a moulding on the semicircular edge or arris, and resting on columns. The *columns* are always single, and on the plan circular, hexagonal, or octagonal; placed on a square plinth, and so low in proportion to their height as to be not more than 3½ diameters high. The shafts are sometimes ornamented with spiral fluted or other work. The capitals are indented, or rather engrailed, with fissures of different lengths and forms variously sloped off, or hollowed out towards the top. (2) They are often decorated with rude imitations of volutes and leaves, being exceedingly varied in their composition. — *Windows*, semicircular-headed, extremely narrow, being sometimes not more than six or eight inches wide to a height of little more than three feet, and splayed or levelled off on the inside through the whole thickness of the wall. — *Walls* of great thickness, without external buttresses.—*Ceilings* open-timbered, with a few specimens of vaulting in crypts. — *Ornaments* very sparingly used, except to capitals and shafts of columns. — *Plan* rectangular and parallelogrammic, being usually divided into a body and chancel separated by an ornamented arch. The chancel occasionally as broad as the nave, and at the eastern part ending in a semicircle. In large churches there is a nave and two side aisles, the latter being divided from the former by ranks of columns; but no transepts appear till the latter part of the period, that is, about 970, when they were generally adopted, with a square tower over their intersection with the nave of the church, and rising a little above the roof. At this date also towers began to appear at the west end, for the reception of bells. The churches of this period were of small dimensions, and it seems doubtful whether they were ever higher than one tier of arches with a range of windows above.

(2)
